Keywords: Wood polymer composites; Acrylic polymers; Design of experiments; Free radical bulk polymerization

Topic: New materials & structured products

Abstract

We have developed a new material consisting of pieces of wood within a matrix of an acrylic polymer, resulting in a transparent or semi-transparent product. This material present quite appealing aesthetics features, opening new possibilities for innovation in decorative products.

Acrylic and methacrylic monomers are in the liquid state for temperature ranges including room temperature. Therefore, it is possible to introduce wood (in our case, walnut wood) in a mixture of acrylic (HPA – hydroxypropyl acrylate) and/or methacrylic monomers (MMA – methyl methacrylate and HEMA – 2-hydroxyethyl methacrylate) in the presence of a chemical initiator (benzoil peroxide). Introducing this reaction mixture along with pieces of wood in a mould, we obtained a transparent polymeric matrix with wood dispersed, through bulk free radical polymerization, i.e., a wood polymer composite.

A 2^{4-1} fractional factorial design was conducted, with the purpose of studying the importance of the composition of these materials in certain selected properties. The sheets produced were characterized by DMTA (to measure T_g), TGA (to assess thermal stability), tensile testing (determination mechanical properties under tensile loads) and HDT (heat-deflection temperature).

1 Introduction

The objective pursued in this work, was to develop a transparent or semi-transparent product with pieces of wood in it, presenting appealing aesthetics features, to be used in the production of furniture and decorative products. Acrylics (products based essentially on poly (methyl methacrylate) - PMMA), are known by their beauty and transparency, which is the reason why they were used in this work to produce the matrix where the pieces of wood were introduced.

The task of introducing a solid material (wood) into another solid (acrylic) can be quite challenging, from a technical point of view. A solution for producing such type of materials, is to make the acrylic suffer a state change that allows the introduction of wood pieces.

Acrylics are thermoplastic polymers and can be processed by injection molding and extrusion (Kirk-Othmer, vol. 19, 1996). Processing temperatures of PMMA in an injection molding process, are in the range of 200-250 ºC, and in an extrusion process are around 180-250 ºC. Wood does not resist to temperatures much higher than 180 ºC (Kirk-Othmer, vol. 25, 1996), and therefore it is not advisable to consider the use of such processes for addressing the goals of this work. Alternatively, one must think in the acrylic before it is produced. Acrylic

and methacrylic monomers are in the liquid state for temperature ranges including room temperature. Therefore, it is possible to introduce wood (in our case, walnut wood) in a mixture of acrylic (HPA – hydroxypropyl acrylate) and/or methacrylic monomers (MMA – methyl methacrylate and HEMA – 2-hydroxyethyl methacrylate) in the presence of a chemical initiator (benzoil peroxide). Introducing this reaction mixture along with pieces of wood in a mould, we managed to obtained a transparent polymeric matrix with wood dispersed in it, through bulk free radical polymerization, i.e., a wood polymer composite (Kumar, 2006).

2 Experimental Design

In order to develop the new material, a 2^{4-1} fractional factorial design was conducted, where the impact of four factors in the relevant physical and chemical properties were systematically assessed. These factors were the presence of HEMA, HPA, dioctyl phthalate (DOP) and walnut wood. Two levels were adopted for each factor (Table 1): 0 and 10 w/w % for the first three factors and presence/absence for the fourth factor, the walnut wood. This experimental design as resolution IV, meaning that no main effect are aliased with any other main effect, or with any two-factor interactions, but two-factor interactions are aliased with each other (Montgomery, 2001). The composition of the samples was completed by adding MMA.

Table 1. Experimental design followed in this work

Test	**Design Factors**			
	***A* – HEMA (w/w %)**	***B* – HPA (w/w %)**	***C* – DOP (w/w %)**	***D* – Walnut**
1	0	0	0	Present
2	10	0	5	Present
3	0	10	5	Present
4	10	10	0	Present
5	0	0	5	Absent
6	10	0	0	Absent
7	0	10	0	Absent
8	10	10	5	Absent

The materials developed in this work are based in PMMA, an hydrophobic polymer with low polarity. Wood, on the other hand, is hydrophilic and polar (Jiang, 2004), due to the existence of hydroxyl polar groups (Castellano, 2004). This fact potentially conduces to weak adhesion in the interface between the polymeric matrix and wood (Jiang, 2004). The introduction of monomers HEMA and HPA in the reaction mixture, has the ability of introducing hydroxyl polar groups on the polymeric matrix, which may lead to higher levels of adhesion between the two phases.

In the literature, it is possible to find some references mentioning that polymers produced by methacrylic monomers (like MMA and HEMA) tend to be hard and brittle, whereas polymers produced by acrylic monomers (the case of HPA), tend to be soft (Kirk-Othmer, vol. 16, 1995). So, the introduction of HPA on the reaction mixture has the goal of promoting internal plasticization (Stevens, 1999), which can be compared with the external plasticization action promoted by the introduction of DOP.

3 Plates Preparation

In order to obtain the plates, one first needs to prepare the mold. Figure 1, presents a scheme with the main stages followed during mold preparation, namely:

(a) - Put in the hotte a glass plate on the horizontal. Apply a silicone spacer on the glass plate creating an open mould.

(b) - Introduce the walnut wood pieces on the mould.

(c) - Put the reaction mixture pre-polymerized on the mould. The pre-polymerization allows for a better temperature control of the exothermal polymerization reaction (Kirk-Othmer, vol. 16, 1995).

(d) - Cover the open mould with an additional glass plate.

(e) - Close the mould with adhesive tape and springs.

(f) – Put the mould on an oven, in the horizontal position. Maintain it at a temperature of 40 ºC for about 20 hours. Conclude the polymerization reaction at a temperature of 90 ºC for about 1 hour.

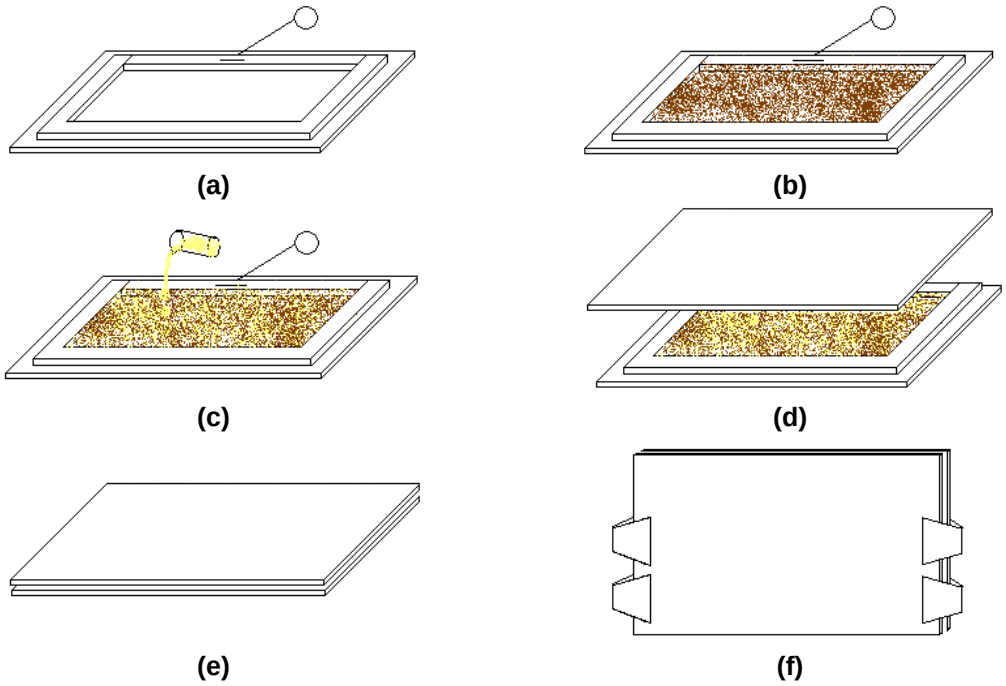

Figure 1. Scheme representing the main stages of preparation of a mold, for obtaining a wood polymer composite.

We have obtained 8 plates following this procedure, with dimensions of approximately 4x27x12 cm corresponding to the 8 runs of the experimental design. We have also produced an additional plate of PMMA, for comparison purposes. Figure 2 presents an example of a plate obtained (test #2 in Table 1).

Figure 2. A typical plate of wood polymer composite, produced in this work (test #2 in the experimental design).

4 Product Characterization

All samples produced were characterized by DMTA (determination of T_g), TGA (study of the thermal stability), tensile testing (determination of tensile mechanical properties) and HDT (heat-deflection temperature). All results obtained were properly analyzed through statistical methods.

DMTA

The tests were made for two frequencies: 1 and 10 Hz; the rate of heating was 2 ºC/min and the equipment was properly calibrated for these conditions. The samples analyzed had dimensions of about 15x8x2 mm. T_g was obtained using the maximum of the curve tan(δ) *versus* temperature.

TGA

The rate of heating was 10 ºC/min; an inert atmosphere of nitrogen was used, whose flow rate was of 10 ml/min. The equipment was correctly calibrated for such conditions, and the samples analyzed had a mass of approximately 10 mg.

Tensile Testing

The tests were made according to the ISO 527 standard, using test specimens of the 1B type and the appropriate equipment. The rate of elongation for the ultimate strength experiment was of 5 mm/min ± 1 mm/min, and for the modulus of elasticity experiment it was of 1 mm/min ± 0,2 mm/min. For the ultimate strength experiment, 3 measurements for each test were performed, and for the modulus of elasticity experiment, 2 measurements were made for each test. The mean values were used for estimating the regression models.

HDT

The heat-deflection temperature (HDT) is a useful indicator of the temperature limit above which polymers cannot be used for structural (load-supporting) applications (Fried, 1995). The tests were made according to the ISO 75 standard, for the method A. For each test of the experimental design, 2 experiments were made for specimens on the horizontal position. The mean values were used for estimating the regression models.

5 Results and Discussion

A summary table of the regression models obtained from the analysis of data collected during the experimental design runs, regarding the glass transition temperature (T_g), ultimate strength (σ_M), elongation at the ultimate strength (ε_M), modulus of elasticity (E_t) and heat-deflection temperature (HDT), can be seen in Table 2.

Table 2. Summary table with the regression models and their associated R^2 and P-values, for the properties: T_g, σ_M, ε_M, E_t and HDT.

Propriety	Regression Model	R^2	P-Value
Glass Transition Temperature (frequency 1 Hz), T_g	T_g (ºC) = 103,81 – 7,44 x **B** -7,61 x **C**	0,8195	0,0138
Ultimate Strength, σ_M	σ_M (MPa) = 40,22 + 18,46 x **D**	0,9497	0,0001
Elongation at the Ultimate Strength, ε_M	ε_M (%) = 2,74 + 1,77 x **D**	0,9447	0,0001
Modulus of Elasticity, E_t	E_t (MPa) = 1862,20 + 456,72 x **D** -324,38 x **BD**	0,8428	0,0098
Heat-Deflection Temperature, HDT	HDT (ºC) = 70,83 - 8,68 x **B**	0,7861	0,0033

As expected, the presence of HPA (internal plasticization) and DOP (external plasticization) in the reaction mixture, does promote the increase of the materials flexibility, because they cause a decrease in the values for T_g.

The TGA analysis determined that the materials produced in this work present a good thermal stability up to temperatures close to 200 ° C.

The introduction of monomers with -OH groups in the reaction mixture did not cause any significant increase in the ultimate strength (σ_M), which means that higher levels of adhesion between the polymeric and the wood phase were not achieved. Thus, the monomers to be used (even in the case of producing flexible materials, through the addition of acrylic monomers), can be chosen on the basis of cost, and not in terms of their polarity features.

The presence of HPA in the reaction mixture (internal plasticization) is the most important factor for determining the flexibility of new materials when subjected to load. Thus, if the intention is to develop materials showing flexibility when subjected to loads, attention should be focused on internal plasticization and not on the external plasticization.

6 Conclusions

We have developed a new material consisting of pieces of wood within a matrix of an acrylic polymer, resulting in a transparent or semi-transparent product. This material present quite appealing aesthetics features, opening new possibilities for innovative decorative products. The results obtained encourage further research in this topic, now focused on specific applications.

SOLUBILITY OF SOME SULFATES IN SUPERCRITICAL WATER

Jesusa Rincón*, Isaac Asencio, Rafael Camarillo and Alicia Martín
Department of Chemical Engineering. Faculty of Environmental Science. University of Castilla-La Mancha. Avda. Carlos III, s/n. 45071 Toledo. SPAIN.

Keywords: catalysts regeneration, sulfates solubility, sub and supercritical water.
Topic: Sustainable process-product development through green chemistry

Abstract

The solubility of aluminium sulfate and sodium sulfate in water has been determined at supercritical temperatures ranging from 350–400°C and sub- and supercritical pressures varying from 150–290 bar. Measured aluminium sulphate and sodium sulfate concentrations ranged from 260–584 ppm and 5–802 ppm, respectively. In the experiments, water was saturated by continuously flowing it through a contacting cell contaning an aqueous salt solution of known concentration (0,5 g/L). The results for sodium sulfate agreed well with other studies which used continuous flow methods. Experiments with aluminium sulfate showed that its solubility in sub- and supercritical water was of the same order of magnitude of that reported in the literature for sodium sulfate at similar conditions.

1. Introduction

Despite the extended use of three-way catalysts in automobile industry for so many years, only a few attempts have yet been made aiming at expanding the durability of gasoline-driven aged three catalysts (TWCs) and in situ regenerating their catalytic performance after applying economically attractive and environmentally friendly techniques. Among these attempts are extraction of contaminants by using liquid solvents such as weak organic acids (e.g., acetic, oxalic, and citric acids) and employment of different combinations of thermal and chemical treatments by oxygen, hydrogen, and chlorine-containing gas mixtures or other chlorine-containing reagents (such us carbon tetrachloride, hydrochloric acid, etc.) to reverse thermal aging by redispersion of the large particles of catalysts noble metals.

However, all of these technologies present some objections, i. e., the efficiency of the process is not complete because of one or several reasons: only partial elimination of the impurities is achieved, there are exclusive treatments for specific pollutants, the recoveries of the catalytic activity and the oxygen storage capacity are limited and wastes streams are generated that need to be treated in order to yield a process environmentally benign. It is for this reason that we propose the use of sub and supercritical water to recycle the TWCs by extracting selectively the pollutants poisoning the catalysts surface. Data recently published (1, 2) suggest that the treatment could work.

Thus, the present study has been undertaken to investigate for the first time the possibility of using sub and supercritical water to improve the catalytic activity and oxygen storage capacity of aged TWCs. More specifically, the solubility in sub and supercritical water of TWCs pollutants such as aluminium sulfate and sodium sulfate is investigated in this work in order to optimize the experimental conditions to perform the extractions that would improve the catalytic and oxygen storage properties of the catalysts.

2. Experimental

2.1 Experimental approach to determine the salt solubility

The goal in solubility studies is to achieve an equilibrium separation between the solvent media and the concentrated solute phase. A common method for determining solubility in sub and supercritical water involves passing water at such conditions through a salt bed and allowing the salt to saturate the water to its equilibrium concentration (3). The effluent from the salt bed is cooled, depressurized, and then analyzed for the salt. However, this method does not work with low-melting salts, since they have a tendency to be transported with the supercritical phase, contaminating the effluent samples and/or plugging the solubility apparatus (4).

As a result, we have developed a method to determine the solubility of salts that avoid these problems. The method takes advantage of the fact that nucleation and precipitation reactions can occur rapidly in SCW. Electolyte solutions of known composition are heated and compressed to conditions at which the solubility is to be determined and maintained at such conditions at an equilibrium cell, for 30 min, to ensure that equilibrium conditions are reached. After that time, water flows through the low flow velocity and long residence time equilibrium cell. The system pressure was maintained with a syringe pump. The equilibrium cell consisted of a 250 cm^3 cylinder. The saturated sub or supercritical water was depressurized through a metering valve. The dissolution of the inorganic salt in water at ambient pressure was collected in a bottle and the dissolved solute quantified by classical chemical SO_4^{2-} analysis. A schematic diagram of the apparatus is shown in Figure 1.

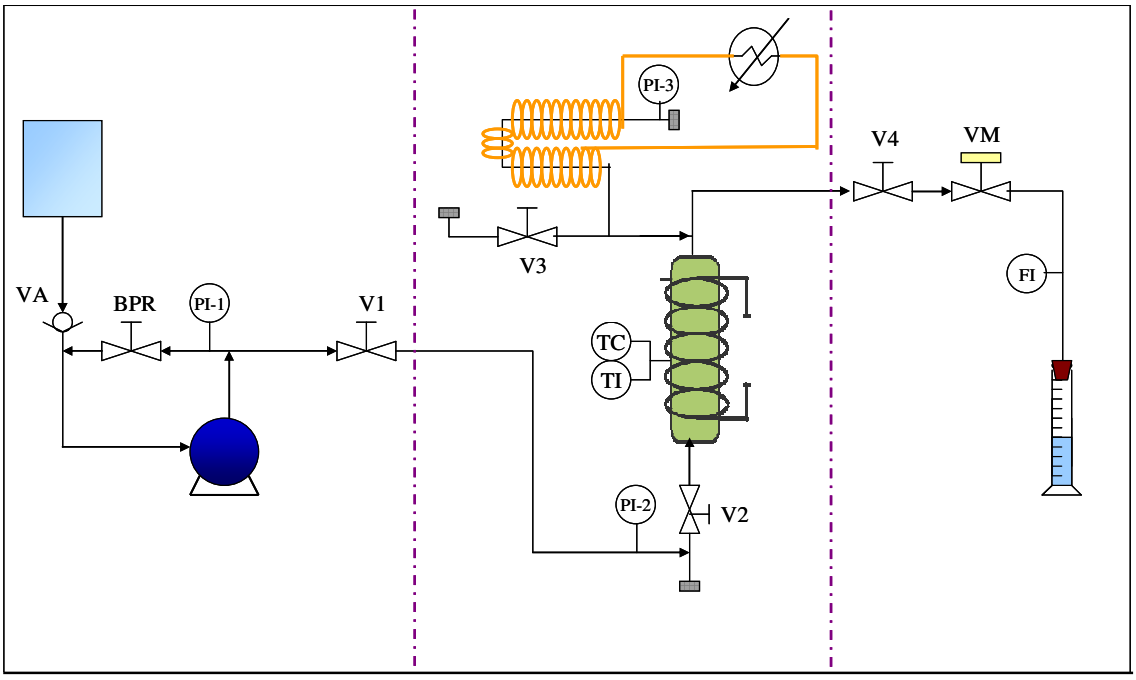

Figure 1. Schematic diagram of the solubility apparatus.

2.2 Materials

The sodium sulfate, Na_2SO_4, and the aluminium sulfate, $Al_2(SO_4)_3{\cdot}18H_2O$, were reagent grade chemicals manufactured by PANREAC. Both of them had a stated purity of 99 mass %. The water was laboratory distilled and deionized.

3. Results and Discussion

The reliability of the experimental procedure was first tested by measuring the solubility of sodium sulfate at two points and comparing it with values reported in the literature. Table 1 shows the results of these experiments. Since the measured solubilities are in good agreement with the literature values (Khan and Rogak, 2004) it may be stated that the experimental procedure for determining the solubility of sulfates is valid. Therefore, it may be used to determine the solubility of aluminium sulfate.

Table 1. Comparison of sodium sulfate solubilities from this work with those from the literature.

		Solubility (ppm)	
T (ºC)	P(atm)	This work	Khan and Rogak, 2004
382	244	802	850
397	243	5	4

For the investigation of the effect of pressure and temperature, the two variables affecting the aluminium sulfate solubility, a Central Composite Design was carried out. In this design there are five experimentation levels: +1, -1, +α, -α, and 0, where 0 corresponds to centre-point and $\alpha=2^{n/4}$, being n=number of variables=2.

For the purpose of analyzing the results, the factors were coded as X_1 and X_2 according to the following equations:

$$X_1 = (P - 218) / 50 \quad (1)$$

$$X_2 = (T - 374) / 20 \quad (2)$$

The 2-Factor Central Composite Design matrix and the values of the responses are shown in Table 2. As can be seen, 12 experiments were necessary: 2^n factorial experiments , 2n star point experiments and four experiments in the centre point. They were carried out in a random order according to the values given in Table 2.

Table 2. The 2-Factor Central Composite Design Matrix and the results for aluminium sulfate solubility.

Experiment Number	Experiment Order	Factor levels		Coded factors		Solublity (ppm)
		P (atm)	T (ºC)	X_1	X_2	
1	8	168	354	-1	-1	267
2	7	268	354	1	-1	486
3	5	168	394	-1	1	324
4	4	268	394	1	1	540
5	1	148	374	-1,41	0	260
6	2	288	374	1,41	0	420
7	12	218	346	0	-1,41	336
8	3	218	402	0	1,41	436
9	6	218	374	0	0	430
10	11	218	374	0	0	287
11	10	218	374	0	0	380
12	9	218	374	0	0	397

The use of the Central Composite Design permits us to express the cell concentration as a polynomial model of the form:

$$Y = a_0 + a_1X_1 + a_2X_2 + a_{11} X_1^2 + a_{22} X_2^2 + a_{12} X_1X_2 \quad (3)$$

where a_0 is the average value of the responses; a_1 and a_2, the temperature and the pressure main effects divided by 2, respectively; and a_{12}, half of the value of the pressure-temperature interaction.

Then, once calculated the parameters of Equation (3), the response funtion was obtained:

$$Y = 403,2 + 111,6\ X_1 + 31,6\ X_2 + 9,5\ X_1^2 - 8,3\ X_2^2 - 0,7\ X_1X_2 \quad (4)$$

where Y is the aluminium sulfate solubility (expressed in ppm), and X_1 and X_2 the coded values of the factors as given by Equations (1) and (2).

Equation (4) fits all data with an error less than 6.4%, indicating good agreement between experimental values and the empirical model.

The experimental solubility data are shown graphically as a funtion of temperature in Figure 2. It can be seen that the solubility of aluminium sulfate varies from 260 to 584 ppm for conditions ranging between 350–400°C and 150–290 atm. It can also be observed in such figure that the solubility increases with increasing pressure, at constant temperature, and with increasing temperature at constant pressure.

These results may be explained by considering that the solvent power of a supercritical fluid mainly depends on its density and that the effect of pressure and temperature on this variable is similar to that found for the salt solubility, i.e., it increases with increasing pressure, at constant temperature, and with increasing temperature at constant pressure.

Finally, it should be noticed that the experimental results obtained cover a wide range of experimental conditions and fill the gap in the information available in the literature. Very few measurements in the water critical region were found for sodium sulfate. Furthermore, the solubility of aluminium sulfate has been determined for the first time at conditions around the critical point of water.

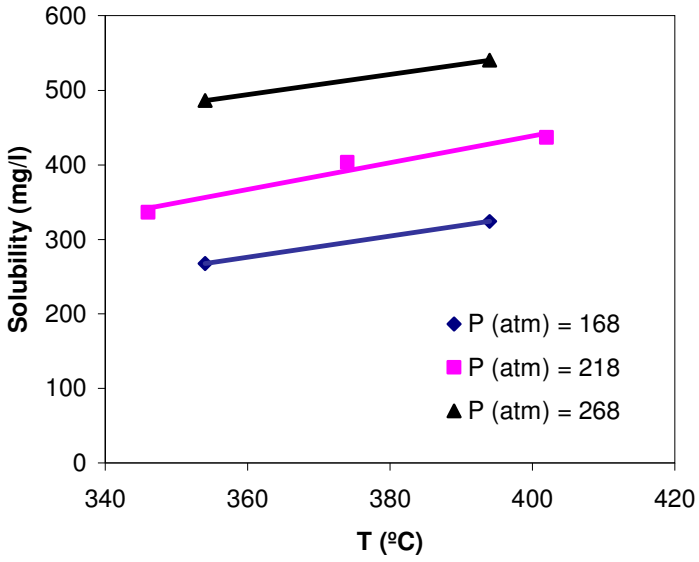

Figure 1. Solubility of aluminium sulfate as a function of temperature.

Topic: Sustainable process-product development through green chemistry.

Abstract

Supercritical fluid technology has been used together with crystal engineering approaches to produce cocrystals. Theophylline (TPL) cocrystals, using the FDA-approved sweetener saccharin (SAC) as a cocrystal former, were generated from ethanol and THF solutions by an Atomization and Anti-solvent (AAS) technique. In this process, high pressure N_2 and CO_2 have been used as supercritical media. The theophylline-saccharin (TPL-SAC) cocrystals morphology was analysed by SEM (Scanning Electron Microscopy) and the potential cocrystalline phase was characterized by DSC (Differential Scanning Calorimetry) and PXRD (Powder X-Ray Difraction) and Fourier Transform-Raman (FT-Raman).

1. Introduction

Bioavailability of an active pharmaceutical ingredient (API), the amount of the intact drug that reaches systemic blood circulation, relates to its aqueous solubility. Some fundamental strategies in improving the aqueous solubility or manipulation of technical properties of drugs include manipulation of solid state structure (polymorph changes or amorphous form), formation of a salt, for liquid drugs adjustment of pH of the solution. Drug delivery technologies, modifying chemical or mechanical environment surrounding the drug molecule, or physically altering the macromolecular characteristics of aggregated particles, have traditionally been considered for improving the solubility of drug substances.

Pharmaceutical cocrystallization is a relatively recent technology which has gained widespread attention for offering an alternative platform in improving the physicochemical properties of API's (e.g., solubility, hygroscopicity and tabletting properties) through the development of new class of crystalline solids, called pharmaceutical cocrystals (Almarsson and Zaworotko, 2004). Cocrystals, also referred as crystalline molecular complexes, may be defined as materials which contain two or more discrete molecular entities in the crystal lattice (Trask and Jones, 2005), incorporating pharmaceutically acceptable guest molecules along with the API. In cocrystals, the API's self-assemble *via* functional groups, such as amides and carboxylic acids, with complementary functional groups of a co-crystal former, resulting in new multi-component structural forms. The choice of pharmaceutical crystalline form can be used to optimize drug

properties, like solubility and dissolution rate, and so cocrystals are emerging as new alternatives (Basavoju *et al.*, 2007).

Cocrystals are often prepared by grinding or using a traditional solution crystallization approaches such as solvent evaporation, cooling or anti-solvent addition. Specifically, in addition to these traditional means of preparing cocrystals, the use of SCF's (Supercritical Fluids) offers new platform that may enhance the rate of cocrystal formation and offers a solvent free product, allowing the single-step generation of microparticles that are difficult or even impossible to obtain by traditional techniques, particularly for substances with thermal sensitivity or structure instability (Rodrigues *et al.*, 2008).

The API under consideration in the current report is theophylline, a drug commonly used in the treatment of asthma and other respiratory diseases. Cocrystallization of theophylline with dicarboxylic acids (e.g., oxalic acid, malonic acid, etc.) had been shown to improve the stability of the drug towards moisture (Trask *et al.*, 2006).

In this work we address the ability of supercritical N_2 and CO_2 for the synthesis of a recently reported theophylline-saccharin cocrystal (Lu *et al.*, 2008), using theophylline as the API and saccharin as the cocrystal former (see Figure 1).

(a) (b)

Figure 1: Chemical structures of theophylline (a) and saccharin (b).

2. Experimental

2.1. Materials

Theophylline (minimum 99% chemical purity) was purchased from BioChemika (USA) and saccharin (99.9%) from Sigma Aldrich (Sweden). Absolute ethanol (99.5%) was supplied by Panreac, THF (99.9%) by Reidel-de Haën, and carbon dioxide and nitrogen (99.998%) by Ar Líquido (Portugal).

2.2. Feed solution preparation

For TPL particle production, 50 mg (0.28 mmol) of theophylline was dissolved in 10 g of ethanol.

For TPL-SAC cocrystal production, a 1:2 mixture of theophylline (22.5 mg, 0.14 mmol) and saccharin (48.6 mg, 0.27 mmol) was dissolved in 10 g of ethanol or THF.

2.3. Particle production

The AAS apparatus was configured for the co-crystallization as described schematically in Figure 2.

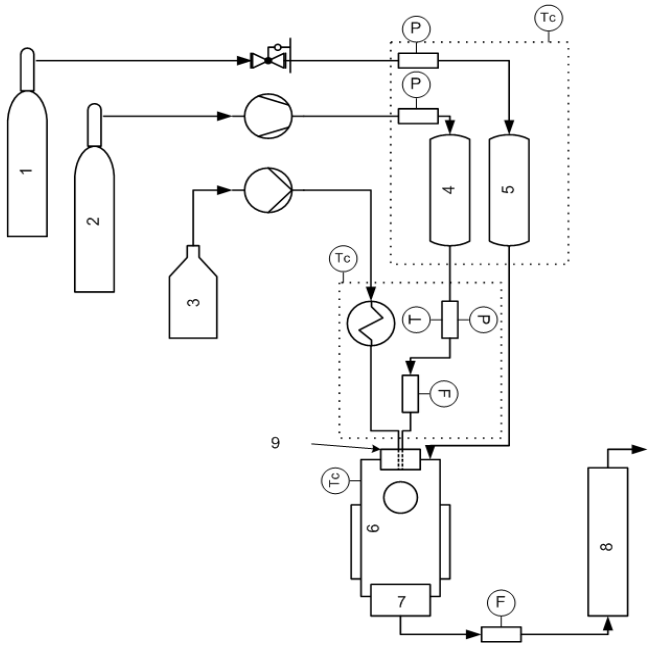

Figure 2: Schematic diagram of the AAS apparatus. 1: N_2 cylinder; 2: CO_2 cylinder; 3: liquid solution flask; 4: temperature controlled CO_2 storage cylinder; 5: temperature controlled N_2 storage cylinder; 6: precipitator; 7: filter; 8: solvent trap; 9: nozzle cap.

The solution containing both substances (theophylline and saccharin) is pumped (by a TSP metering pump, model 2396-74) through a coaxial nozzle (where it mixes with the supercritical fluid in a small mixing chamber prior to its depressurization into a precipitator vessel. The gas (N_2 or CO_2) is compressed by a Newport Compressor (model 46-13421-2).

Gas flows through the nozzle are measured by a Rheonik flowmeter (model RHM007) and pressures are measured by PX603 transducers from Omega. Temperatures are controlled in an air chamber or in a water bath by T-type thermocouples and Ero Electronic controllers (model LDS). A secondary current of dry gas (N_2) is fed into the precipitator to enhance the solvent extraction from the particles. The particles are collected in a filter at the precipitator exit.

A smaller nozzle orifice was used for CO_2 processing to limit the CO_2 flow rate and nozzle freezing due to strong depressurizations. A nozzle with a 200 μm orifice was used in the experiments with N_2 whereas a nozzle with a 80 μm orifice was used in the experiment with CO_2.

2.4. Particle characterization

The particle size and morphology were examined by SEM (Philips XL30, The Netherlands). Particles of representative samples were gold sputtered in an argon atmosphere at room temperature before the examination.

Thermal analyses (DSC) of the samples were performed on a Thermal Advantage DSC Q1000 V9.8 (TA instruments-Waters, LLC) which was calibrated for temperature and cell constants using indium and sapphire. Samples (1-2 mg) were crimped in non-hermetic aluminium pans and scanned at 10°C/min under a dry nitrogen purge (50 ml/min).

The PXRD patterns were collected on a Siemens DIFFRACplus 5000 powder diffractometer (tube voltage 40 KV and current 40 mA) with Cu Kα radiation (1.54056 Å). Each sample was

scanned between 5º and 50º 2θ with a step size of 0.01º. The instrument had previously been calibrated using a silicon standard.

The Raman analysis (Perkin Elmer NIR FT-Raman 1700X spectrometer equipped with InGaAs detector) was also performed. However, the results are not presented here.

3. Results and discussion

3.1. Particle morphology

The morphology of the processed particles showed some differences between theophylline and TPL-SAC cocrystals: the former having plate-shape morphology and the latter with a more spherical form (Figure 3). However, the morphology of TPL-SAC cocrystals was not affected by the varying processing conditions in AAS (Table 1).

Table 1. Experimental conditions for particle production. *P* is the pressure before the nozzle; *t* is the temperature in the mixing chamber; *R* is the volumetric flow-rate ratio of the aqueous feed to the supercritical fluid; t_{max} is the sample melting point; $\Delta_{fus}h$ is the enthalpy of fusion. TPL sample corresponds to the pure processed theophylline; TPL-SAC 1 to 5 correspond to processed theophylline-saccharin cocrystals under different experimental conditions.

Reference samples	Supercritical Fluid	*P* (MPa)	*t* (ºC)	Solvent	*R* (mL/NL)*	Melting Point t_{max} (ºC)	$\Delta_{fus}h$ (J/g)
TPL	N_2	12.8	60	Ethanol	0.11	272.6 ± 0.1	155.2 ± 7.2
TPL-SAC 1	N_2	8.0	50	Ethanol	0.04	197.7 ± 0.2	133.9 ± 12.0
TPL-SAC 2	N_2	8.0	50	THF	0.04	197.8 ± 0.2	124.5 ± 4.1

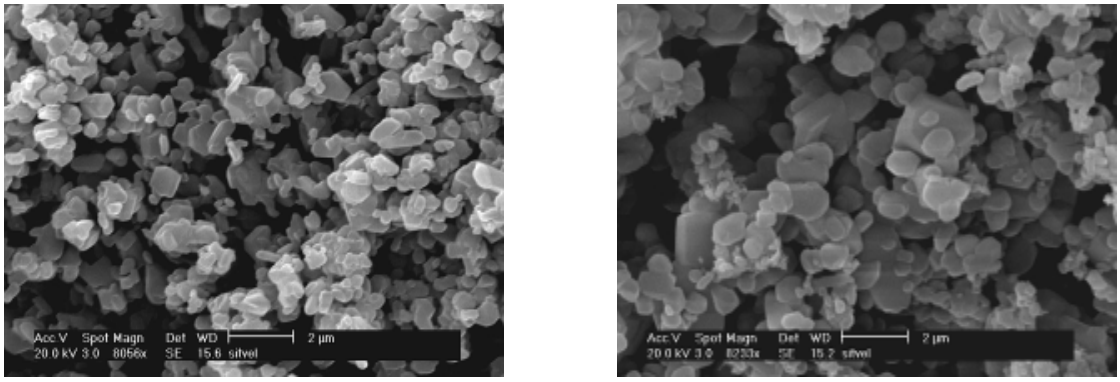
(b)



(c) (d)

Figure 3: SEM images of AAS processed samples: (a) TPL; (b) TPL-SAC 1; (c) TPL-SAC 2; (d) TPL-SAC 5.

3.2. Cocrystalline solid state characterization

Cocrystalline phase characterization and identification was carried out using classical solid state characterization techniques such as DSC, PXRD and Raman (not presented). As can be seen in Figure 4, TPL-SAC cocrystals have a single melting transition at ~197.6ºC that is different from those of the corresponding pure components and TPL-SAC cocrystals (1:1) (produced by solvent crystallization), suggesting a new cocrystalline phase formation.

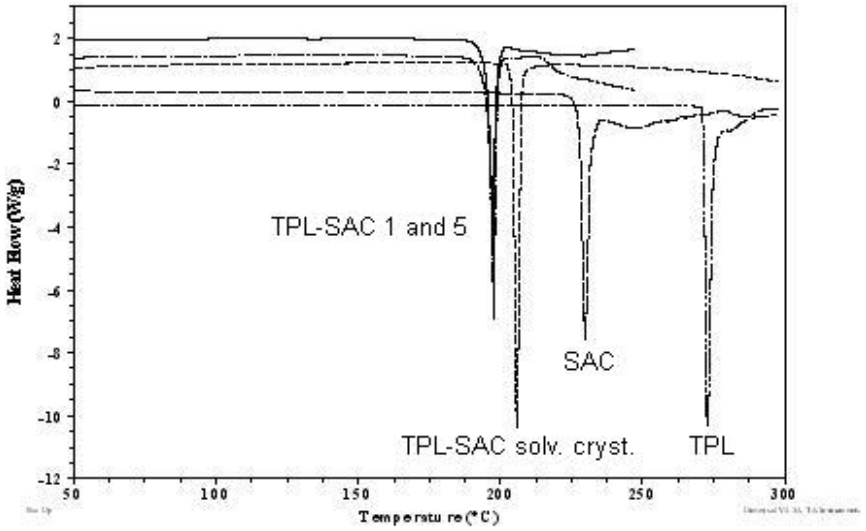


Figure 4: DSC heating curves of pure theophylline (TPL), pure saccharin (SAC), and TPL-SAC cocrystals produced by solvent crystallization and TPL-SAC cocrystal samples 1 and 5.

The powder X-ray diffraction (PXRD) pattern of TPL-SAC cocrystals (TPL-SAC sample 1) showed distinct peaks compared to the crystalline TPL (anhydrate or hydrate), SAC and reported TPL-SAC cocrystals (1:1). PXRD analysis together with FT-Raman (not presented) strongly suggests the formation of a new cocrystalline (possibly with 1:2 stoichiometry) or polymorphic form of 1:1 TPL-SAC cocrystal. Our current efforts in obtaining pure crystals of this new phase and a follow-up single crystal X-ray study (including the simulated XPRD pattern) will hopefully confirm the true nature of the cocrystalline phase.

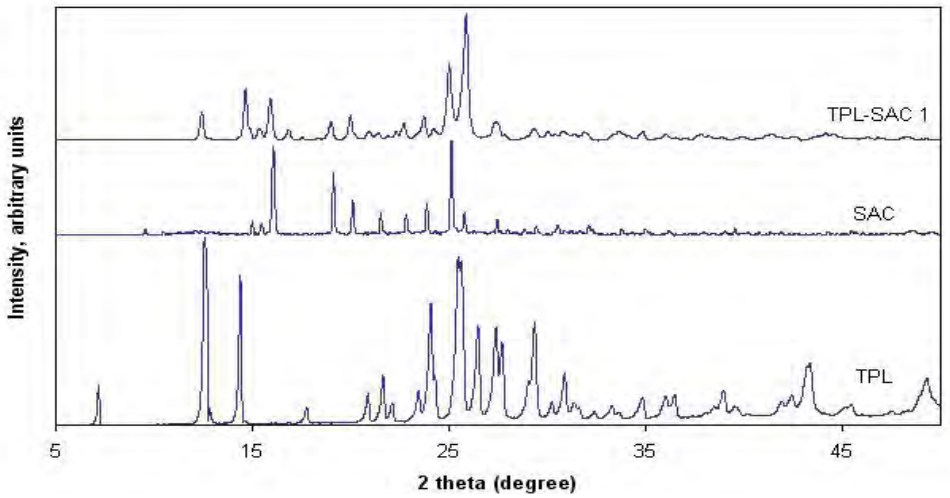

Figure 5: PXRD pattern of pure theophylline (TPL), saccharin (SAC) and TPL-SAC 1 cocrystal sample.

4. Conclusions

Pharmaceutical cocrystal micro- and nanoparticles can be produced using SCF's by AAS process and to our knowledge this is a first report on the topic. The cocrystal formed between theophylline and saccharin using a 1:2 molar ratio, is most likely a new cocrystalline phase with a distinct morphology compared to the pure processed theophylline.

Further work is currently in progress for extensive characterization of this cocrystal and analysis of its physicochemical properties, particularly its stability under relative humidity conditions. In addition, other cocrystal systems are under investigation towards an in-depth understanding of the cocrystal formation mechanism in supercritical fluids.

Keywords: CO_2 capture, CaO, MCM-41, Temperature Programmed Desorption (TPD)
Topic: Sustainable process-product development through green chemistry.

Abstract

CaO / MCM-41 sorbents (2.5, 5 and 10% in weight of CaO) were prepared by mixing raw materials in water at room temperature and they were characterized and tested as CO_2 adsorbents at low temperature (50ºC). TPD experiments carried out after exposition of the sorbents to CO_2 showed that the sorbents capture CO_2 at this low temperature, and that gas is mainly desorbed near 200ºC (CO_2 adsorbed). The gas retention at this low temperature is slow, being necesary near 18 hours to achieve the maximum capture, that is obtained with the 2.5% CaO / MCM-41 sorbent (9.8 mg CO_2 / g sorbent). The maximum CO_2 capture at 200ºC decreases at values of 1.3 to 2.1 mg CO_2 / g depending on the sorbent used. Five cycles of adsorption at 50ºC and desorption up to 550ºC were carried out with all the sorbents, founding reproducibility in the capture higher than 85%, better than that obtained with CaO, which normally captures CO_2 at higher temperatures as $CaCO_3$ and experiments a much higher loss-in-capacity.

Introduction

In the short term, fossil fuels will continue to be the main energy supply, and technologies associated with CO_2 capture and storage are increasingly considered to achieve these emission reductions (IPPC Special Report, 2005). Developed post-combustion technology consists in the flue gas absorption in an aqueous solutions with amines. Adsorption at low temperatures is considered one of the potential alternatives to absorption processes, with added advantages, and the development of adsorbents with a high CO_2 selectivity and adsorption capacity is needed. Modified carbons, zeolites, mesoporous materials, metal oxides and amines supported have been tested as adsorbents, but no work has been done by using calcium bases supported on MCM-41 materials.

The aim of this work was to study the carbon dioxide adsorption of sorbents prepared by aqueous mixture at room temperature of CaO and a MCM-41 support. Temperature-programmed desorption (TPD) analysis of these materials previously treated with CO_2 was used. The influence of time of contact, percentage of CO_2 in the flow gas and temperature of contact in the adsorption were studied. The behaviour in consecutive adsorption-desorption cycles was also tested in order to check the stability of the adsorbents, comparing to a commercial CaO adsorbent.

Materials and methods

MCM-41 material used as support was prepared with two silicon sources, heated under reflux and calcined at 550ºC (Blanco et al., 2004). The molar composition of the gel was: 1.00 SiO_2: 0.25 Na_2SiO_3: 0.25 CTMABr:0.10 TMAOH:100 H_2O. The CaO /MCM-41 sorbents were prepared at the same conditions that CaO/smectite sorbents (Renedo et

* Corresponding author. Tel + 34-42-202026. E-mail:fernandj@unican.es

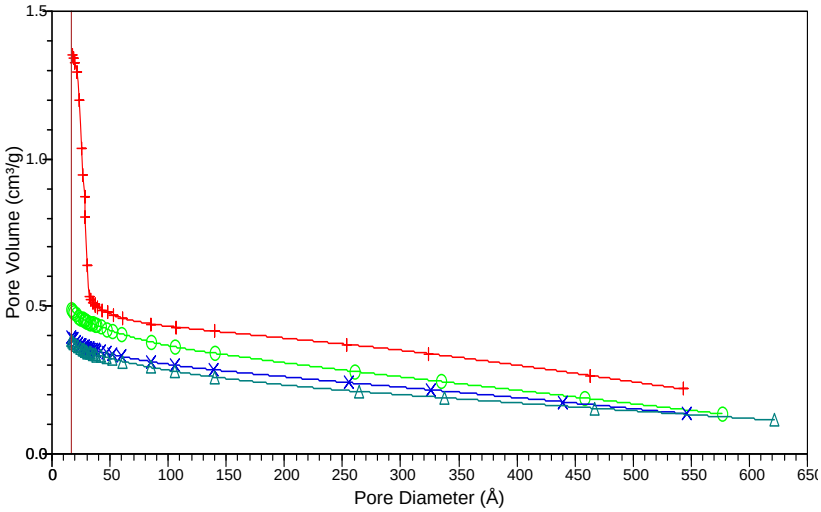
al., 2006) by mixing at room temperature CaO with distillate water, adding the MCM-41 support and stirring for 30 minutes, filtering and drying at 110ºC to constant weight. The weight percentage of CaO /support in the sorbents prepared was 2.5%, 5% and 10% and the water to solid ratio was 10.

The prepared sorbents were characterized by determining their BET specific surface area and pore size distribution by N_2 adsorption in a Micromerics ASAP-2000 apparatus.

Experiments of CO_2 adsorption and desoption were performed by using an AutoChem II 2920 equip. Initially, the sample was outgassed in He flow by thermal treatment from room temperature to 550ºC. After being cooled to the temperature at which adsorption was carried out (50 to 200ºC) the adsorbent material was contacted to a mixture of CO_2 in He (10% normally, but 50% was also checked) for times varying from 30 minutes to 24 hours. The reversible adsorbed CO_2 was removed by treatment of the sample in He flow, normally for 30 minutes at the adsorption temperature. Then, Temperature Programmed Desorption (TPD) experiments were carried out by heating the sample with a ramp of 10ºC/min until 550ºC in a constant He flow. The signals obtained with a Thermal Conductivity Detector (TCD) after the TPD experiment were integrated in order to obtain the amounts of CO_2 desorbed, previous calibration of the device. To study the regenerability of the adsorbents, after holding the sample temperature at 550ºC during 30 minutes, the temperature was decreased to the initial value and the adsorption-desorption cycle repeated.

Results and Discussion

BET specific surface area of the sorbents showed a drastic reduction with respect to the MCM-41 support when $Ca(OH)_2$ (formed by hydration of the CaO) was added. This area decreased gradually as the $Ca(OH)_2$ increased (from 1085 m^2/g of the MCM-41 support to 204, 196 and 159 m^2/g in sorbents with 2.5%, 5% and 10% CaO /support respectively) The pore size distribution also evidence that the $Ca(OH)_2$ produces the closure of the pores in the mesopore range, as can be seen in figure 1, with data of the accumulated pore volume.



----o----2.5% CaO/MCM-41 -----Δ---- 5 % CaO/MCM-41
----x----10% CaO/MCM-4 ------¡--- MCM-41 support

Figure 1. Accumulated Pore Volume for the prepared sorbents and the MCM-41 support.

In order to maintain the structure of the support, prepared by calcination at 550ºC, sorbents were treated in Helium flow up to 550ºC. It was proved previously that CO_2 is not retained in these sorbents as $CaCO_3$, which decomposes at 625ºC.

Figure 2 shows the results of TPD experiments obtained with 2.5% CaO / MCM-41 sorbent over five cycles, after 30 minutes exposition to a 10% CO_2 in He flow. Three peaks are showed, with maximums at 100ºC, 200ºC and 550ºC, being the most important peak centered at 200ºC. Similar profiles were observed by using the 5% or 10% CaO / MCM-41 sorbents, indicating that the CO_2 is adsorbed, because the desorption takes place mainly near 200ºC, at temperatures much lower than 625ºC.

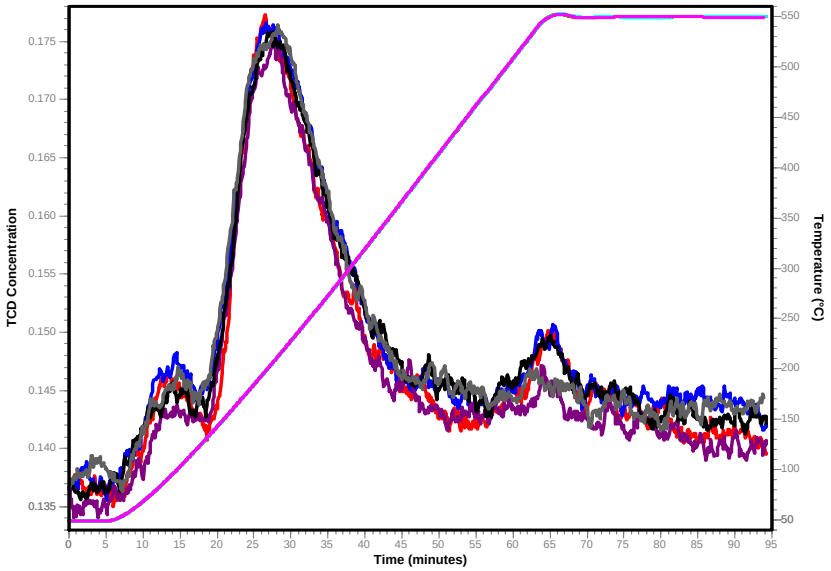


Figure 2. TPD results after adsorption for 30 minutes with 10% CO_2 in He for 2.5% CaO / MCM-41 sorbent during 5 cycles.

Data of the CO_2 amount desorbed in the different peaks for 2.5% CaO / MCM-41 sorbent, identified by the temperature of the peak maximum (100ºC, 200ºC and 550ºC) are presented in figure 3. This figure shows that the CO_2 desorption values are quite similar in the five cycles tested, mainly the peaks desorbed with maximum at 200ºC.

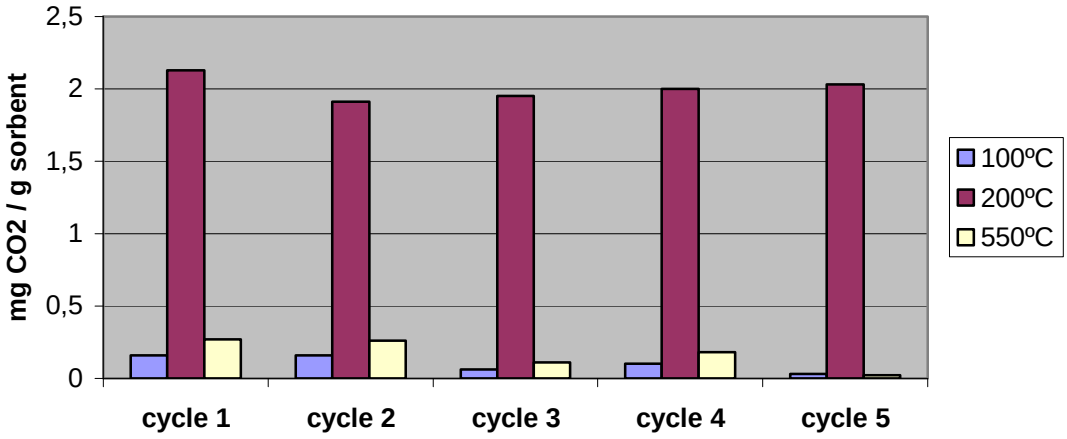

Figure 3. Milligrams of CO_2 desorbed per gram of sorbent in the different peaks for 2.5% CaO / MCM-41 sorbent during five cycles after adsorption at 50ºC with 10% CO_2 for 30 minutes.

To study the influence of the CO_2 concentration and the time of contact with CO_2 in the retention of this gas, several experiments were performed. An experiment of five cycles with a gas flow of 50% CO_2 in He for 30 minutes at 50ºC was carried out and results were compared with those obtained with 10% of CO_2 in He for 10% CaO / MCM-41 sorbent. The same value, 3.2 mg CO_2 captured / g of sorbent, was obtained in the first cycle for both conditions, being the differences in the values in the rest of the cycles lower than 2%. Therefore, no influence of the CO_2 concentration in the retention values was found.

After the exposition of 10% CaO / MCM-41 sorbent to 10% CO_2 at 50ºC in consecutive cycles for times varying from 30 to 1440 minutes (24 hours), TPD experiments were performed with reversible desorption times of 30 minutes. The time of reversible desorption was also checked, varying from 30 to 480 minutes, in the same experiment. Table 1 shows the values of the variables programmed in each cycle in this experiment.

Cycle number	Adsorption time (min)	Desorption time (min)
1	30	30
2	120	30
3	240	30
4	480	30
5	480	120
6	480	240
7	480	480
8	960	30
9	1440	30
10	30	30

Table 1. Times of adsorption and reversible desorption planned in each cycle for the experiment carried out with 10% CaO / MCM-41 sorbent, Temperature of adsorption 50ºC.

Results obtained are showed in figure 4. No influence of the reversible desorption time (cycles 4, 5, 6 and 7) is observed, being 30 minutes time enough to eliminate the reversible CO_2 adsorbed. Nevertheless the retention of CO_2 in the sorbent increases as the contact time does, as can be seen in figure 4, cycles 1 to 4, 8, 9 and 10, reaching approximately the equilibrium near 18 hours, which indicates the slow retention rate of CO_2 in the basic sorbent.

Figure 4. Results of CO_2 desorption corresponding to the programmed cylces for the experiment showed in Table 1 for 10% CaO / MCM-41 sorbent after 10% CO_2 adsorption at 50ºC.

Table 2 shows the desorption values for the three sorbents prepared, obtained after 30 minutes of CO_2 adsorption at 50ºC, and the results after CO_2 adsorption at 50ºC during 18 hours, obtained in consecutive cycles for each sorbent. It can be seen that after 30 minutes of CO_2 adsorption, the 10% CaO / MCM-41 sorbent captures more CO_2 than the other sorbents. Results of the maximum CO_2 adsorption capacity (measured by the desorption data obtained in the TPD experiments after adsorption during 18 hours) show that an important increase in the CO_2 captured takes place, being the sorbents with less CaO content (2.5%) that obtain the highest capacity of capture (9.8 mg CO_2 / g). This is an important result in order to optimize the preparation of these sorbents with the minimum cost.

	CO_2 desorbed after 30 minutes of exposition to CO_2 at 50ºC (mg CO_2 / g sorbent)	**CO_2 desorbed after 18 h of exposition to CO_2 at 50ºC (mg CO_2 / g sorbent)**	**CO_2 desorbed after 18 h of exposition to CO_2 at 200ºC (mg CO_2 / g sorbent)**
2.5% CaO / MCM-41-2	2.6	9.8	1.3
5% CaO / MCM-41-2	2.8	8.6	1.6
10% CaO / MCM-41-2	3.2	8.0	2.1

Table 2. Data of the CO_2 desorbed, in mg CO_2 / g sorbent, obtained in TPD experiments after flow of 10% CO_2 in He at the temperatures and times indicated. Values at 200ºC were obtained after the cycle at 50ºC for 18 hours.

To study the influence of the temperature in the CO_2 captured, a consecutive cycle of adsorption at 200ºC during 18 hours was performed in each sorbent, after the first

exposition at 50ºC during 18 hours and desorption. Results of the TPD are also showed in Table 2. They indicate, according to the desorption profile of these sorbents, that an enormous reduction in the CO_2 retained takes place.

Figure 5 shows the desorption results obtained over five consecutive cycles of 30 minutes at 50ºC with all the prepared CaO / MCM-41sorbents. It can be observed that the reproducibility in the capture was higher than 85%. When commercial $Ca(OH)_2$ was used as sorbent, without support, CO_2 retention values were higher than those obtained with the prepared sorbents. After 30 minutes of exposition to CO_2 at 50ºC, 22 mg CO_2 / g commercial $Ca(OH)_2$ was desorbed and after 18 hours of exposition to CO_2 at 50ºC, the value was 29 mg CO_2 / g. But desorption was done up to 800ºC. These desorption values in commercial $Ca(OH)_2$ correspond mainly to the decomposition of the $CaCO_3$ formed, over 600ºC, and the loss-in-activity found was 42% in the fifth cycle of 30 minutes and 27% after the third cycle of 18 hours.

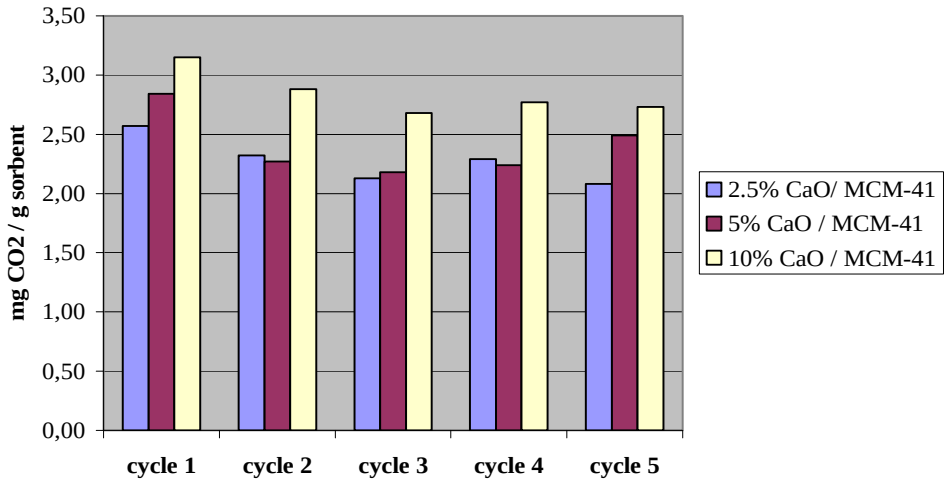

Figure 5. Desorption results (mg CO_2 / g) obtained during five consecutive cycles of 30 minutes of exposition to CO_2 at 50ºC in all the CaO / MCM-41sorbents prepared.

Apart from the slight reduction in the total CO_2 desorbed after the first cycle, the values obtained with the CaO /MCM-41 sorbents are approximately constant. This results confirm, as other author did (Feng et al., 2006) that the good distribution of CaO particles in an inert porous framework does not present the problem of loss in capacity that normally suffers calcium oxide after cycles of carbonation / decarbonation, that is an obstacle for its use in cyclic processes.

Abstract

In this work two mesoporous carbon replicas were prepared using a porous clay heterostructure - obtained from a Portuguese natural motmorillonite - as template and furfuryl alcohol as carbon source. The samples where characterized by X-ray powder diffraction, scanning electron microscopy and N_2 adsorption at low temperature. The ash content and the pH at the point of zero charge were also determined. The previous acidification of the surface revealed to be not important since the samples prepared with and without the previous impregnation with *p*-toluenesulfonic acid presented the same textural, structural and morphological characteristics. The surface chemistry properties must also be similar since the carbons present the same pH at the point of zero charge.

1 Introduction

The extensive use of porous carbons is the natural consequence of their properties, such as high specific surface areas, large pore volumes, chemical inertness and good mechanical stability. Most carbons are primarily microporous, however there are numerous potential applications for which materials with wider pores, preferably in mesopore range, would be advantageous (Lee, 2006). In this sense, since the pioneer work of R. Ryoo *et al.* (1999), much effort has been made concerning the preparation of Ordered Mesoporous Carbons (OMCs). Such materials are important for applications in emergent areas such as energy storage in double-layer supercapacitors, in addition to the common applications as adsorbents and catalyst supports (Lee, 2006).

The synthesis of OMCs is generally made by the templating approach. The main steps are: i) infiltration of the porous structure of a mesostructured inorganic material (template) by the carbon precursor (usually a polymer or pre-polymer); ii) polymerization of the infiltrated substance; iii) carbonization of the nano-composites formed and iv) elimination of the template. Depending on the type of mesostructured silica used as template, carbons with different structures and pore sizes can be prepared (Fuertes, 2004).

Although silicas of MCM and SBA families have been extensively employed as templates, the use of other inorganic matrixes has also been envisaged. In fact, in the literature there are some studies where clay based solids or zeolite frameworks were used, as is the case of the work developed by D. Nguyen-Thanh and T.J. Bandosz (2006) that, to our knowledge, is

* Angela Martins. Fax nº: 003518317267, e-mail: amartins@deq.isel.ipl.pt

the only study were the potentialities as template of a porous clay heterostructured (PCH) for mesoporous carbons preparation were evaluated.

In the present study a new approach of templated synthesis of mesoporous carbons was tried, using a PCH as inorganic matrix and furfuryl alcohol as carbon precursor. The preparation procedure was monitorized by the results of nitrogen adsorption at – 196 ºC. The carbons were also characterized by X-ray powder diffraction, scanning electron microscopy, quantification of the ash content and evaluation of the pH of the point of zero charge.

2 Experimental

The PCH used was prepared from a natural Portuguese montmorillonite from Benavila (Alentejo, Portugal). Briefly, the preparation procedure consisted in the intercalation of cetyltrimethylammonium bromide (Aldrich) and decylamine (Aldrich, 95%) to direct the interlamelar hydrolysis of tetraethylortosilicate (Aldrich, 98%), that will form the pillars in the galleries of the modified clay. The clay:amine:TEOS proportion used was 1:20:150. Finally, the sample was calcined at 650 ºC for 5 h with a ramp of 1 ºC min^{-1}.

Two carbon samples were prepared, CF and CF-TS, differing only in the fact that in the preparation of CF-TS a previous impregnation of the PCH with p-toluenesulfonic acid (Carlo Erba, 99%) was made. Following the conditions reported in Kim (2006), we used the proportion 4.3 mg of *p*-toluenesulfonic acid *per* g of furfuryl alcohol to be impregnated in the matrix. The purpose of this procedure was to increase the surface acidity of the solid which will catalyse the polymerization process of the carbon precursor, that is, furfuryl alcohol. The infiltration of this organic compound onto the PCH porosity was carried out by incipient wetness at room temperature, using a volume of alcohol equal to the total pore volume of the matrix. The material was then placed in a covered recipient and heated overnight at 95 ºC, after what it was carbonized in a horizontal tubular oven (Thermolyne, model 21100) at 700 ºC for 1 h, under nitrogen flow (6.7 cm^3 s^{-1}). The obtained composites are designated as CF/PCH and CF-TS/PCH. After removing the inorganic template using HF, the samples were thoroughly washed with distilled water until pH 7.

The porosity modifications promoted by the samples preparation methodology were studied by N_2 adsorption at low temperature, using an automatic apparatus ASAP2010. Before the essays the samples were outgassed at 300 ºC for 2 h under vacuum better than 10^{-2} Pa.

The ash content of the carbons was estimated by the mass residue left after the combustion of the samples in air, according to a procedure adapted from the Spanish Norm UNE 32 111. Approximately 1 g of dried carbon was heated in a furnace equipped with a Eurotherm 2416 controller according to the temperature regime: from room temperature to 500 ºC in 10 min, kept for 30 min at this temperature and then to 815 ºC in 15 min and kept for 2 h 30 min. After cooling, the residue was weighted (Mettler AE 240 analytical balance) and the ash content (mean of three essays) was estimated by dried mass of carbon. The pH of the point of zero charge (pH_{PZC}) was determined by reverse mass titration, following the method proposed by Noh and Schwarz (1989). The pH of several carbon slurries in distilled water (in %) up to 10 was measured after stirring for, at least, 24 h. The pH_{PZC} corresponds to the pH of the plateau of the curve obtained plotting the equilibrium pH as a function of solid weight fraction.

X-ray powder diffraction (XRD) patterns were obtained in a D8 Advance Bruker diffractometer with automatic data acquisition, using Cu$K\alpha$ graphite-monochromatised radiation. Data were acquire by step scanning from 0.7º to 6º 2θ, with a step size of 0.03º 2θ, a time per step of 4 s and 40 kV and 40 mA in the X-ray tube. The morphological characterization was made by scanning electron microscopy (SEM) in a Jeol Model JSM –

6301F microscope using electron secondary beams at 15 kV with samples coated with gold (coating chamber: Jeol JFC-1200).

3 Results and discussion

The determination of the ash content of carbon replicas is very important since it is an expedite method to check the matrix removal. The results obtained demonstrated that the procedure used efficiently removed the PCH since the ash content found were in the order of 0.4 %.

The N_2 isotherms at -196 ºC displayed in Fig. 1a) exemplify the evolution of porosity observed using either of the two samples preparation strategies used in this study. The curves obtained with PCH and carbon samples exhibit an important uptake at low pressures indicating the presence of a developed microporosity, associated with a mesoporous structure responsible for the continuous increase of the N_2 uptake that occurs at high relative pressures and the hysteresis loops observed. The isotherm of the carbon obtained using *p*-toluenesulfonic acid, CF-TS/PCH (not shown) practically overlaps that of CF/PCH. The composites obtained after carbonization present curves very close to a isotherm of type I according to the IUPAC classification (IUPAC, 1984). This result reveals that a fraction of the PCH microporosity, and all of its mesoporous structure, is filled with carbon after the carbonization of furfuryl alcohol. It is interesting to note that, after the removal of the inorganic matrix by HF treatment, the sample exhibits an adsorption capacity higher than that presented by the PCH used as template.

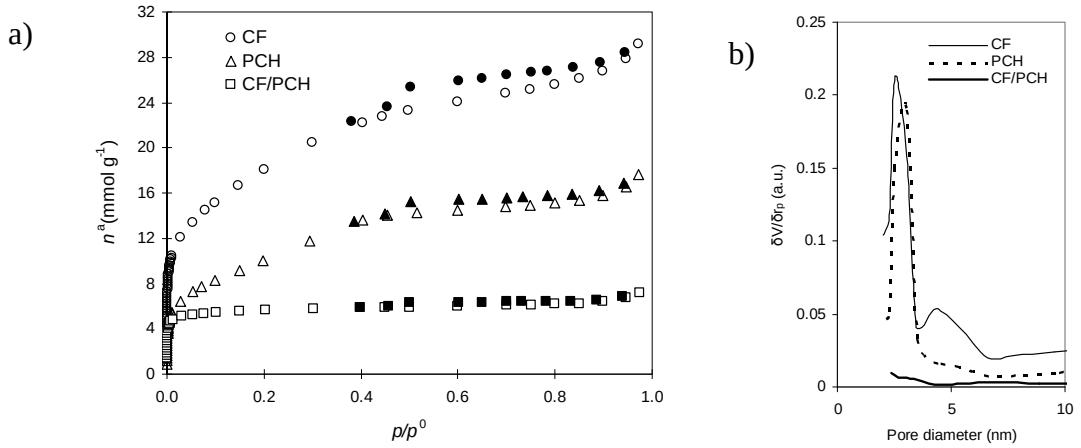

Figure 1 - Nitrogen adsorption-desorption isotherm at – 196 ºC for the samples indicated (a) and respective mesopore size distribution (b).

Table 1 presents the apparent specific surface area, S_{BET}, assessed applying the BET equation (in the range $0.05<p/p^0<0.15$) and the microporous volume, V_{micro}, obtained using the α_s method, taking as reference the isotherm reported in Rodríguez-Reinoso et al. (1987). In Table 1 the values of the the total porous volume, V_{total}, estimated from the amount of N_2 adsorbed at $p/p^0=0.95$ and the values of the mesoporous volume, V_{meso}, obtained by the difference between V_{total} and V_{micro} are also listed.

Table 1 - Textural characteristics of the samples.

Sample	S_{BET} m^2 g^{-1}	V_{micro} (α_s method) cm^3 g^{-1}	V_{meso} cm^3 g^{-1}	V_{total} (p/p^0 = 0.95) cm^3 g^{-1}
PCH	818	0.44	0.14	0.58
CF/PCH	452	-	-	0.24
CF	1469	0.64	0.34	0.98
CF-TS/PCH	428	-	-	0.24
CF-TS	1433	0.64	0.35	0.99

In line with the previous discussion based on the isotherms configuration, the values reported in Table 1 show that, the preparation of the composite materials, CF/PCH and CF-TS/PCH, resulted in the loss of 50 % of the apparent surface area and of the porous volume estimated for the template. The removal of the template leads to a very important increase of all the parameters assessed. The two carbon replicas are texturally identical and their S_{BET} and V_{total} are almost double than those presented by the starting PCH. The gain of V_{total} results of the increase of both micro and mesoporous volumes. Although in the overall process a more accentuated development of the mesoporous structure is observed, the porosity of the carbons materials is formed by, approximately, 60 % of microporores and 30 % of mesopores.

These results are different from those obtained by of D. Nguyen-Thanh and T.J. Bandosz (2006) focussed on the preparation of carbon replicas from PCH templates using sucrose as carbon source. In fact, the carbons replicas obtained by these authors present a higher mesoporous volume than that of the template used, and a smaller microporous volume. These different results seem to point out the potentialities of PCH structures to derive carbon replicas with distinct textural characteristics that can be tailored to a specific application. It must also be noted that the carbon materials obtained in the present study have both micro and mesoporous volumes higher than those reported by D. Nguyen-Thanh and T.J. Bandosz (2006)

The mesopore size distribution was made according the Broekhoff-de Boer method, in a version simplified (Lukens, 1999) with the Frenkel-Halsey-Hill equation (BdB-FHH). The curves displayed in Fig.1b show that the methodology followed permitted the preparation of carbons presenting a by-modal mesoporous size distribution, the smallest mesopores being slightly narrow than those of the PCH.

The textural characteristics of the carbons prepared with and without surface acidification (samples CF and CF-TS in Table 1) allow us to conclude that the surface acidity of the PCH is sufficient to catalyze the furfuryl alcohol polymerization and the methodology followed permitted that the replicas maintain the layered structure of the matrix in some extension.

However, this inherit of the templated structural features was not revealed in the X-ray diffraction analysis, as can be verified in the patterns shown in Fig. 2. SEM images of the PCH and the two carbon replicas prepared (Fig. 3) also show morphological changes upon the materials preparation. The particles dimensions of the carbon materials are smaller than those of the template.

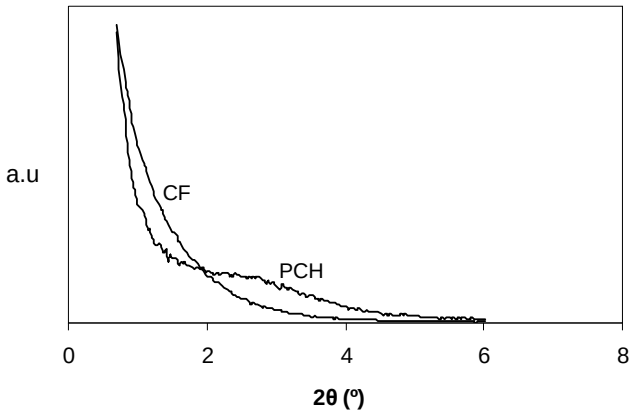

Figure 2 – XRD patterns for PCH silica template and carbon sample CF.

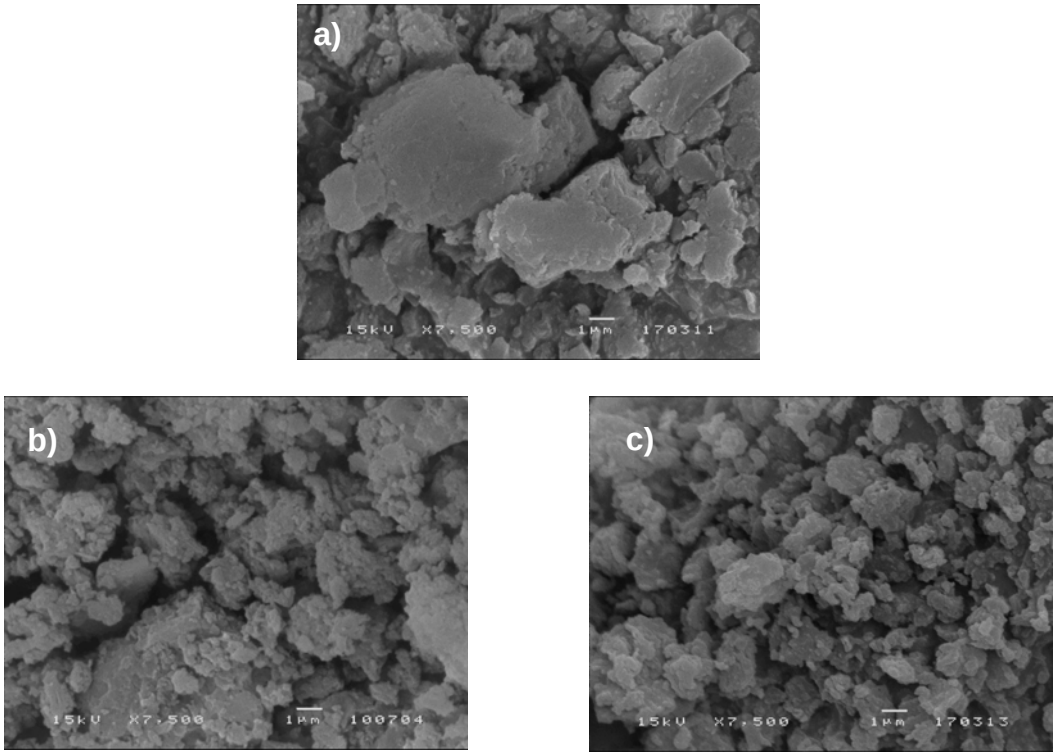

Figure 3 – Scanning electron microscopy images of: a) PCH; b) CF and c) CF-TS.

To have a first assess of the surface chemistry properties, the pH_{PZC} of the carbons was determined. No difference between the two samples was observed, since both presented a pH_{PZC} of 3.5, that is, both are acidic carbons. This result reveals once again that the previous impregnation with *p*-toluenesulfonic acid is not reflected in the carbons characteristics. The acidic properties of the surface are important for several applications, namely as adsorbents, and is usually obtained only after post-preparation treatments, what permits to envisage a large number of potential applictions for these materials.

4 Conclusions

The results obtained in this study reveal that the surface acidity of the PCH was sufficient to catalyze the furfuryl alcohol (carbon precursor) polymerization. In fact, none of the characteristics evaluated distinguished the carbon replica prepared with the previous acidification of the matrix surface from that where the furfuryl alcohol was directly impregnated. The samples obtained are characterized by an acid surface and a developed microporosity associated to a triple mesoporous volume than that presented by the starting PCH. A bi-modal mesoporous size distribution was obtained; the smallest mesopores being slightly narrow than those of the PCH. The textural and surface chemistry properties of the carbon prepared make them very promising materials, not only for adsorption purposes but also as catalysts or catalysts supports. In this sense, in the near future these materials could be used as supports for homogeneous catalysts.

Keywords: nitrate reduction, activated carbon, bimetallic catalysts, water treatment.
Topic: Sustainable process-product development through green chemistry.

Abstract

The influence of calcination and reduction temperatures on the catalytic properties of Pd-Cu and Pt-Cu bimetallic catalysts supported on activated carbon for the reduction of nitrates was studied. The catalysts were prepared according to different methodologies and the respective activities and selectivities for the reduction of nitrate in water with hydrogen were assessed. It was found that the different preparation conditions lead to different catalytic activities and selectivities. For all the catalysts, the activity decreases by increasing calcination and reduction temperatures, whereas the effect on the selectivity is not uniform. In all the preparation conditions tested the Pd-Cu pair seems to be more selective for the transformation of nitrate into nitrogen.

1 Introduction

Nitrate concentrations in surface water and especially in groundwater have increased in many locations in the world, including in Europe. The catalytic reduction with hydrogen has been suggested in the literature as a promising method for nitrate removal from water without the drawbacks of the conventional methods (Pintar, 2003; Prusse and Vorlop, 2001). This process was reported for the first time by Vorlop and Tacke (1989) and consists in the reduction of nitrate towards nitrogen over bimetallic catalysts in the presence of a reducing agent. Nitrite as intermediate and ammonium as by-product are considered the main disadvantages of this process (Pintar, 2003). The activity and selectivity of the bimetallic catalysts are highly dependent on the preparation method, on the way the noble metal is promoted, on the metal/promoter ratio and on the operation conditions (Matatov-Meytal and Sheintuch, 2005). Alloying of metals may result in important changes in their activity and selectivity in catalytic reactions (Epron et al., 2002). The selection of the support is also important for this process since it has been shown that the support affects the catalysts activity and selectivity (Matatov-Meytal and Sheintuch, 2005).

2 Experimental

The active metals were supported on a commercial activated carbon NORIT GAC 1240 PLUS (ACo). The catalysts were prepared by incipient wetness co-impregnation, from aqueous solutions of the corresponding metal salts (H_2PtCl_6, $PdCl_2$, $Cu(NO_3)_2$). Then, the samples were dried at 100 ºC for 24 h. Different temperatures were selected for calcination (T_{Cal}) under a nitrogen flow for 1 h and reduction (T_{Red}) with hydrogen for 3 h. No calcined and no reduced catalysts (N_{Cal} N_{Red}) were also evaluated. The contents of noble and

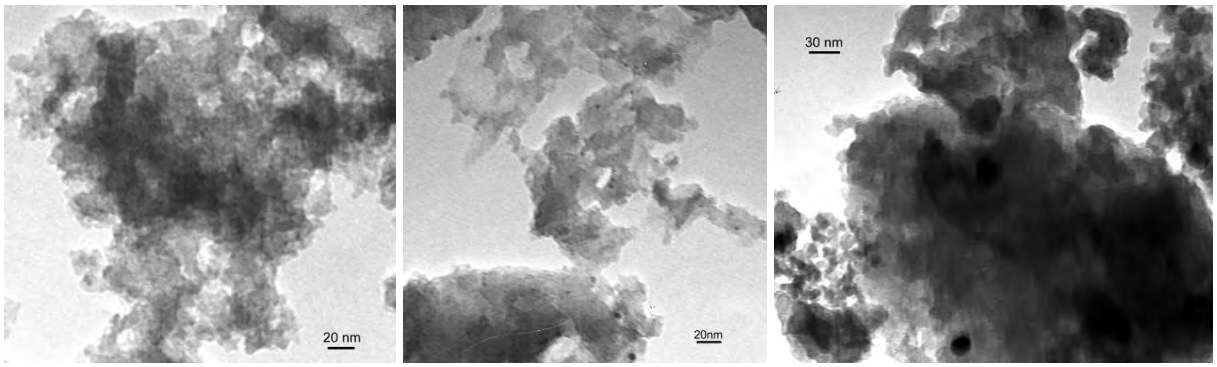
promoter metals were maintained constant at 1%wt and 0.3%wt, respectively. The catalysts were characterized by N_2 adsorption at 77 K, XRD, TEM and XPS.

The catalytic tests were carried out in a semi-batch reactor, at room temperature and pressure, with an initial nitrate solution of 100 ppm and using hydrogen as reducing agent. CO_2 was used as a buffer (pH 5.5). In standard tests, the catalysts were in contact with an hydrogen flow during 15 min before introducing the nitrate solution in the reactor. Nitrate and nitrite concentrations were simultaneously determined by HPLC. The concentrations of ammonium ions were quantified using a convenient selective electrode. pH values were also measured.

3 Results and Discussion

3.1. Catalysts characterization

The BET surface area of the support is 869 m^2/g. Two samples, with 2%Pd-1%Cu and with 2%Pt-1%Cu (a total metal loading higher than that used in the samples tested in this work), were also characterized by N_2 adsorption, and it was verified that the textural parameters remained almost unchanged compared to the unloaded activated carbon. Therefore, it was assumed that the surface areas of the supported metal catalysts are not significantly different from the original activated carbon.



a) b) c)

Figure 1. TEM images of 1%Pd-0.3%Cu_ACo catalysts a) T_{Cal}=200ºC N_{Red}, b) T_{Cal}=200ºC T_{Red}=100ºC and c) T_{Cal}=400ºC T_{Red}=400ºC.

TEM images of the samples revealed that particle size depends on the preparation conditions. In both series (Pd-Cu and Pt-Cu) the evolution of the particle size with the temperatures used during calcination/reduction presents a similar trend (see the Pd-Cu series as an example in Figure 1). No major differences were observed in the morphology of the catalysts neither calcined nor reduced; in fact in this sample no particles can be detected, probably due to the fact that this catalyst was not heat treated and consequently no metal particles were generated. For the catalyst T_{cal}=200ºC N_{red} (Figure 1 a) a few not well defined particles can be observed. In the case of 1%Pd-0.3%Cu_ACo T_{cal}=200ºC T_{red}=100ºC (Figure 1 b) it is already possible to see some well defined particles. These observations suggest that metals are well dispersed on the support. From the distribution particle size it was observed that these catalysts mainly present particle sizes between 3 and 4 nm. For the 1%Pd-0.3%Cu_ACo catalyst with T_{cal}=400ºC T_{red}=400ºC (Figure 1 c) TEM analysis shows the presence of not only small particles in the range of 5-6nm, but also larger particles. Summarizing, from TEM images it can be concluded that an increase in the calcination and reduction temperatures causes an increase in the particle size of the crystallites.

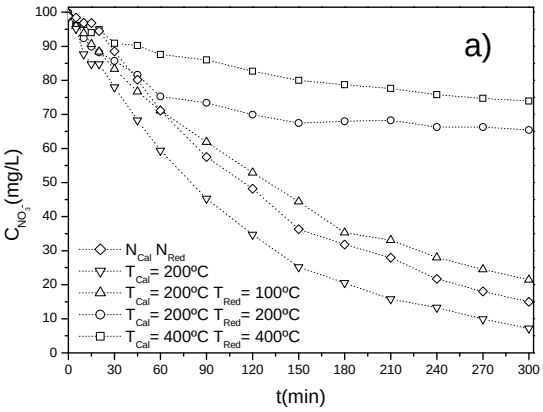
All the catalysts were analyzed by XRD to determine the metal particle size and to identify if the metals were isolated or forming alloys. In 1%Pd-0.3%Cu_ACo and 1%Pt-0.3%Cu_ACo catalysts, XRD of the catalysts do not show any intense peak of both metals, which could be due to the low amount of metal loaded and, on the other hand, could be taken as an indication of a good metal dispersion on the support. TEM images support this conclusion. Only in the XRD spectra of the catalysts 1%Pd-0.3%Cu_ACo and 1%Pt-0.3%Cu_ACo with T_{cal}=400ºC T_{red}=400ºC significant peaks of the metals can be observed, which is also indicative that these catalysts present larger particles than those treated at lower temperatures. In addition, in these XRD spectra it can be observed that the peaks of Pd and Pt are slightly displaced to the right, which is indicative of the formation of alloys.

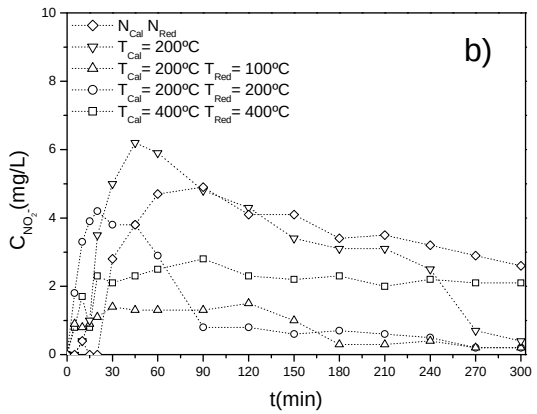
3.2. Catalytic tests

The effects of calcination and reduction temperatures on the catalysts activity and selectivity during the reduction of nitrates were studied.

As can be seen in Figure 2 and Figure 3 the reduction of nitrate is quite different depending on the supported metal and the preparation conditions. For all the catalysts the activity decreases by increasing the calcination and reduction temperatures. This effect is more pronounced for the pair Pd-Cu. For high calcination and reduction temperatures the Pt-Cu catalysts are more active than the Pd-Cu catalysts. However, using a low reduction temperature or not carrying out the reduction step, the Pd-Cu catalysts are the most active. The order of activity for both catalysts is similar: T_{Cal} = 200ºC N_{Red} > N_{Cal} N_{Red} > T_{Cal} = 200ºC T_{Red} = 100ºC > T_{Cal} = 200ºC T_{Red} = 200ºC > T_{Cal} = 400ºC T_{Red} = 400ºC, with nitrate conversion values after 5h of 93, 85, 79, 35 and 25%, and 77, 73, 64, 57 and 53%, respectively for the Pd-Cu and the Pt-Cu catalysts. Epron et al. (2002) studied the influence of oxidizing and reducing procedures on the activity of a Pt-Cu bimetallic catalysts supported on alumina, and also observed that the poorest activity was achieved when the catalyst was oxidized and reduced at 400 ºC. They concluded that this lower activity results from the destruction of the interactions between copper and platinum, and a subsequent migration of copper towards the alumina support. Therefore, an enrichment of platinum in the surface was noticed. This eventually decreases the catalytic activity. In the present work, the results obtained by XPS confirm an increase of the Pd content on the surface of the catalyst with the increase of calcination and reduction temperatures.

The nitrite concentration goes through a maximum (Figures 2b and 3b) and the ammonium concentration increases with the nitrate conversion (Figures 2c and 3c), indicating the occurrence of consecutive/competitive reactions. The reduced catalysts give rise to similar nitrite concentrations, which, particularly in the case of the Pt-Cu catalysts, are much lower than the concentrations obtained with the non-reduced catalysts. This can be explained by the fact that for the catalysts only calcinated or not heat treated the active sites for nitrite reduction are not completely formed. As can be seen by TEM images, no particles were observed for these catalysts, indicating a good dispersion of the metals or, most probably, that the metal is still in its salt form (especially for the non heat treated sample). Therefore, in these conditions, the metal could not be very active for nitrite reduction. It is well assumed that nitrite reduction occurs principally on monometallic sites (Epron et al., 2001; Prusse and Vorlop, 2001). A similar trend is observed for ammonia, but in this case the highest concentrations were measured for the Pd-Cu catalysts, probably because the conversion for these catalysts is higher than for the Pt-Cu catalysts.





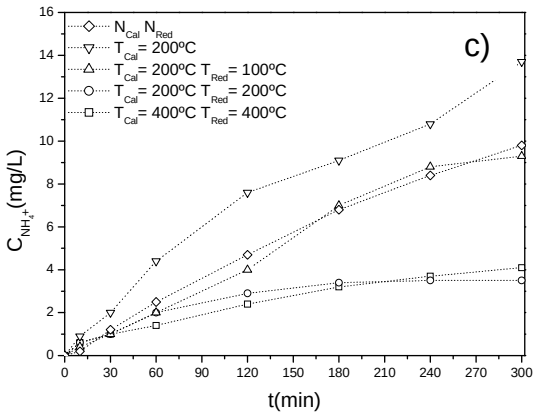


Figure 2. a) NO_3^-, b) NO_2^- and c) NH_4^+ concentrations as a function of time during nitrate reduction in the presence of 1%Pd-0.3%Cu_ACo catalysts ($C_{NO3\text{-}i}$ = 100 mg/L, catalyst = 0.5 g/L, pH = 5.5, Q_{H2} = 100 Ncm^3/min, Q_{CO2} = 100 Ncm^3/min, T = 25 ºC).

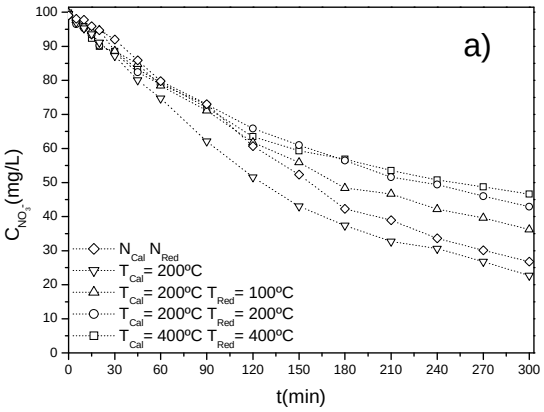

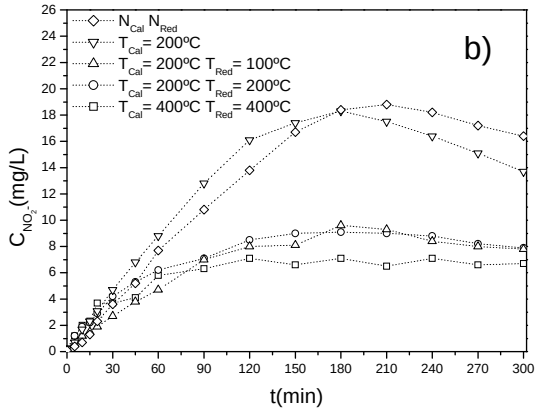

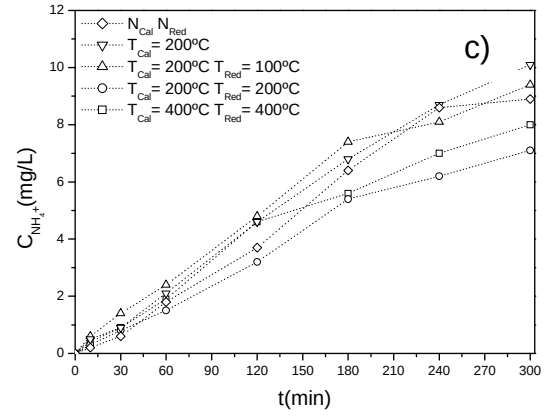

Figure 3. a) NO_3^-, b) NO_2^- and c) NH_4^+ concentrations as a function of time during nitrate reduction in the presence of 1%Pt-0.3%Cu_ACo catalysts ($C_{NO3\text{-}i}$ = 100 mg/L, catalyst = 0.5 g/L, pH = 5.5, Q_{H2} = 100 Ncm^3/min, Q_{CO2} = 100 Ncm^3/min, T = 25 ºC).

Considering that these catalysts have the same amount of metals, the different performances should be related to the metal dispersion and/or active sites. Calcination and reduction at high temperatures lead to a decrease in the nitrate conversion in comparison with the catalysts treated at low temperatures; this can be explained by the metal surface area decreasing due to alloying and/or sintering. Preparation of the catalysts at higher temperatures results in larger metal particles with an overall loss of catalytic activity.

For both catalysts the highest nitrogen selectivities were observed for the catalysts T_{Cal} = 200 ºC T_{Red} = 200 ºC, being the catalysts T_{Cal} = 400ºC T_{Red} = 400 ºC the most selective into ammonium. Nevertheless, for the Pt-Cu catalysts, the selectivities into nitrogen were not too different from sample to sample. The two catalysts corresponding to T_{Cal} = 400 ºC T_{Red} = 400 ºC present different nitrate conversions but similar high selectivities into ammonia. According to Sá et al. (2005) the decrease in the selectivity of the process with the increase of the reduction temperature, can be attributed to alloying of the metal. Yoshinaga et al. (2002) suggested that a dilution of Pd faces takes place during alloying. This leads to an increment in the number of isolated Pd atoms, which are suggested to be active sites for the ammonium formation. The pair Pd-Cu is more selective into nitrogen than the pair Pt-Cu, which presents higher selectivity into ammonia. The pair Pd-Cu is the most active but is also the most selective into nitrogen, which is the desirable end product.

To investigate the influence in the activity and in the oxidation state of the catalyst of passing a hydrogen flow during 15 min before the introduction of nitrates in water, the catalytic reduction of nitrates was performed in different conditions than those normally used. For that purpose, the catalyst (sample 1%Pd-0.3%Cu_ACo T_{Cal} = 200 ºC N_{Red}) was introduced in the reactor together with the concentrated nitrate solution, i.e. after 15 min of flowing water with hydrogen. Figure 4 shows the evolution of nitrate reduction in this experiment.

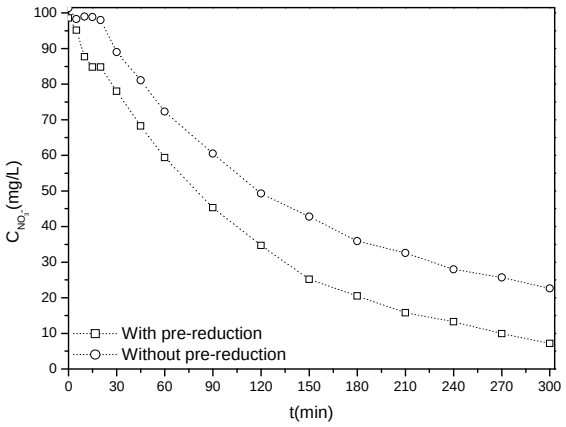

Figure 4. NO_3^- concentration as a function of time during nitrate reduction in the presence of 1%Pd-0.3%Cu/AC catalysts with and without a pre-reduction in situ (C_{NO3^-i} = 100 mg/L, catalyst = 0.5 g/L, pH = 5.5, Q_{H2} = 100 Ncm^3/min, Q_{CO2} = 100 Ncm^3/min, T = 25 ºC).

Figure 4 shows that, for the experiment without pre-reduction in situ, the reaction only begins after a period of 20 min, and a displacement in the corresponding curve relative to the observed for the experiment with pre-reduction was observed. With the exception of this initial lag, the performance of the catalysts in these experiments is similar. This induction period can be explained by the time necessary to reduce in-situ the catalyst with hydrogen and, probably, the presence of hydrogen in water allows a rearrangement of the metal phase. To confirm this hypothesis, a XPS analysis of the catalyst was carried out after and before being in contact with hydrogen during 15 min. The XPS results lead to the conclusion that the contact with hydrogen in water changes significantly the surface composition of the

catalyst. A decrease of the metal surface ratio (Pd/Cu) is observed probably due to a palladium migration towards the support and/or a migration of copper to the top of palladium. The results obtained permits to conclude that the catalyst can be reduced in-situ by hydrogen (avoiding the ex-situ reducing step).

4 Conclusions

The reduction of nitrate is quite different depending on the supported metal and the preparation conditions. For all the catalysts, the activity decreases with the increase of calcination and reduction temperatures, whereas the effect on the selectivity is not uniform. The calcination and reduction at high temperatures are inadequate due to the formation of higher metal particles. The contact with hydrogen in water has an important effect in the catalysts activity. The performance of the catalysts is maximised for low calcination and reduction temperatures. For all the preparation conditions tested the Pd-Cu pair seems to be more selective in the transformation of nitrate into nitrogen.

Topic: Sustainable process product development through green chemistry (New materials & structured products).

Abstract

In this work a set of MOR, BEA, MFI and FER zeolites were submitted to alkaline treatment in order to extract silicon from the framework, resulting in the generation of mesoporosity inside the zeolite crystals. The samples where characterized by X-ray powder diffraction and scanning electron microscopy. The textural properties were studied by N_2 adsorption at low temperature. The effect of the desilication treatment on the acidity was evaluated by the model reaction of catalytic craking of n-heptane and by pyridine adsorption followed by infrared spectroscopy.

1 Introduction

Zeolites are crystalline aluminosilicates with a unique combination of properties, such as, high surface area, well-defined microporosity, high thermal stability and intrinsic acidity. These materials have been widely used in catalysis as well as in separation and purification fields (Yousheng, 2006).

The modification of the purely microporous character of zeolites is an important aspect that can be explored. In fact, a more efficient performance of zeolites as catalysts can be envisioned upon enhanced accessibility to the active sites and shortening of the diffusion path length in the micropores (Groen, 2006).

The traditional dealumination treatments, in steam or acidic medium, generally induce limited mesoporosity in zeolites and directly impact on the acidic properties due to depletion of Brönsted acidity (Groen 2006). Recently, the controlled extraction of framework silicon in alkaline medium, referred to as desilication treatment, was proposed by Groen *et al.*(2004). This treatment has resulted in a promising methodology to produce extended mesoporosity in zeolites crystals, without impacting on the acidity (Groen, 2006). In recent years, several publications on this subject have emerged, especially focused on MFI type zeolite.

2 Experimental

MOR, BEA, MFI and FER zeolites, supplied by Zeolyst, with a Si/Al ratio of 10, 12.5, 25 and 27.5, respectively, were desilicated using the optimised experimental conditions described by Groen *et al.* (2004). For example, approximately 2.64 g of MFI zeolite sample was vigorously stirred in 80 mL of 0.2 M NaOH solution at 65 ºC for 30 min. The suspension was then centrifuged and washed with distilled water. The alkaline-treated samples were converted into the H-form by three consecutive exchanges with 1 M NH_4NO_3 solution for 3 h. Then the suspension was filtered, the solid was dried overnight, and finally calcined in air flow at 500 ºC for 3 h. The samples were characterized by X-ray powder diffraction (XRD) in a Philips PW 1710 diffractometer with automatic data acquisition (APD Philips (v3.6B) software) and scanning electron microscopy (SEM) in a Jeol Model JSM – 6301F microscope

Angela Martins. Fax nº: 003518317267, e-mail: amartins@deq.isel.ipl.pt

using electron secondary beams at 15 kV and samples coated with gold (coating chamber: Jeol JFC-1200). The porosity modifications were studied by N_2 adsorption at low temperature, performed in an automatic apparatus ASAP2010. Before the essays the samples were outgassed at 300 ºC for 3 h under vacuum better than 10^{-2} Pa. The possible changes in the acidity were evaluated by the model reaction of n-heptane cracking. The reaction was performed in a continuous flow reactor at 350 ºC under a total pressure of 1 bar. The catalysts were pre-treated at 500 ºC *in situ* for 10 h under nitrogen flow of 36 L h^{-1} g^{-1}. Experiments were made for 90 min using a flow of 3 mL h^{-1} of n-heptane (molar ratio N_2/n-C_7=9) and WHSV=20.5 h^{-1}. The reaction products were analysed by an on-line gas chromatograph Hewlett-Packard 6890 series with a flame ionisation detector (FID), using a capillary column PLOT-Al_2O_3/KCl. The surface acidity of selected samples was also characterized by adsorption of pyridine followed by infrared (IR) spectroscopy. Before the experiments, the self-supported wafers were outgassed at 300 ºC for 2 h under vacuum better than 10^{-2} Pa. To estimate the strength of the acid sites, after pyridine chemisorption the samples were successively outgassed for 1.5 h at 200, 300 and 400 ºC. After each treatment the IR spectrum was registered in a Nicolet 6700 FTIR spectrometer.

3 Results and discussion

The XRD patterns of the parent and treated samples (Fig. 1) do not evidence significant losses of cristallinity during the alkaline treatment. The preservation of the long-range crystal ordering is especially evident in the case of MFI structure since the diffractograms of the parent and the treated samples are practically coincident. These results are in line with that reported by Groen *et al.* (2004) although in our study a less accentuated decrease in the peaks intensity was observed.

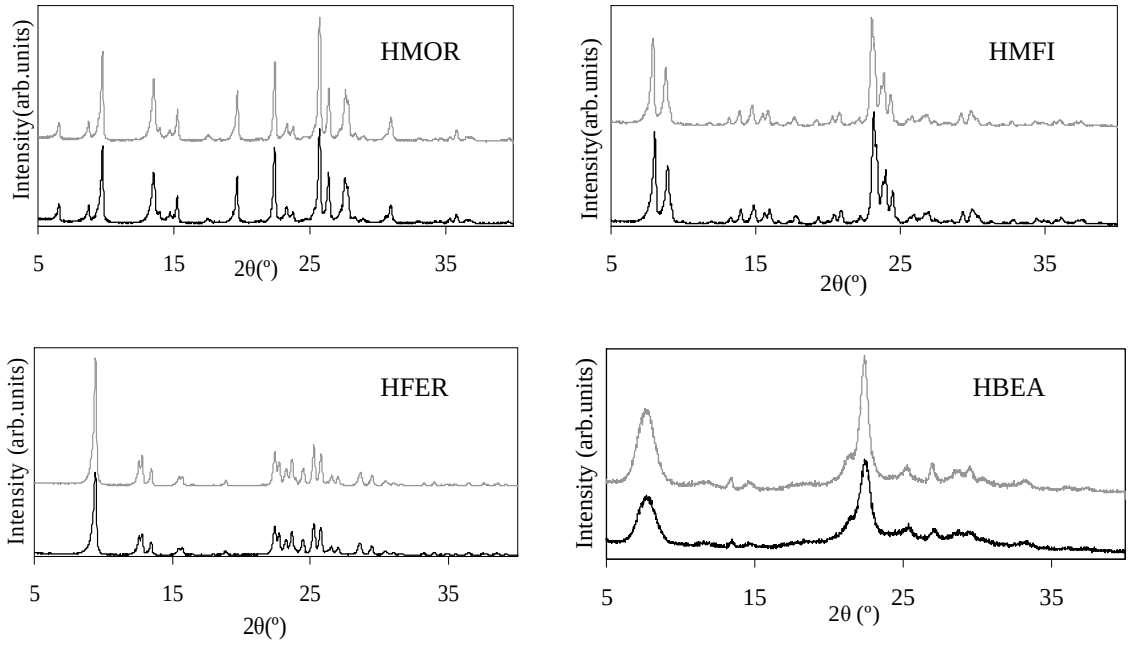

Figure 1 – XRD patterns for parent (grey lines) and alkaline treated samples (back lines).

The nitrogen adsorption/desorption isotherms displayed in Fig. 2 show that for all the starting structures a sharp rise in uptake at low pressure is observed, confirming the predominant microporous character of solids. The presence of a significant mesoporous structure is observed only for BEA. For the majority of the essayed structures, the alkaline treatment

results in the development of mesoporosity that is evidenced by the increase of the nitrogen uptake at high relative pressures and the presence of a more or less pronounced H4 type hysteresis loop. In the case of BEA the treatment did not promote any change in the zeolite structure since the isotherms of the parent and treated samples are coincident in the overall range of relative pressures.

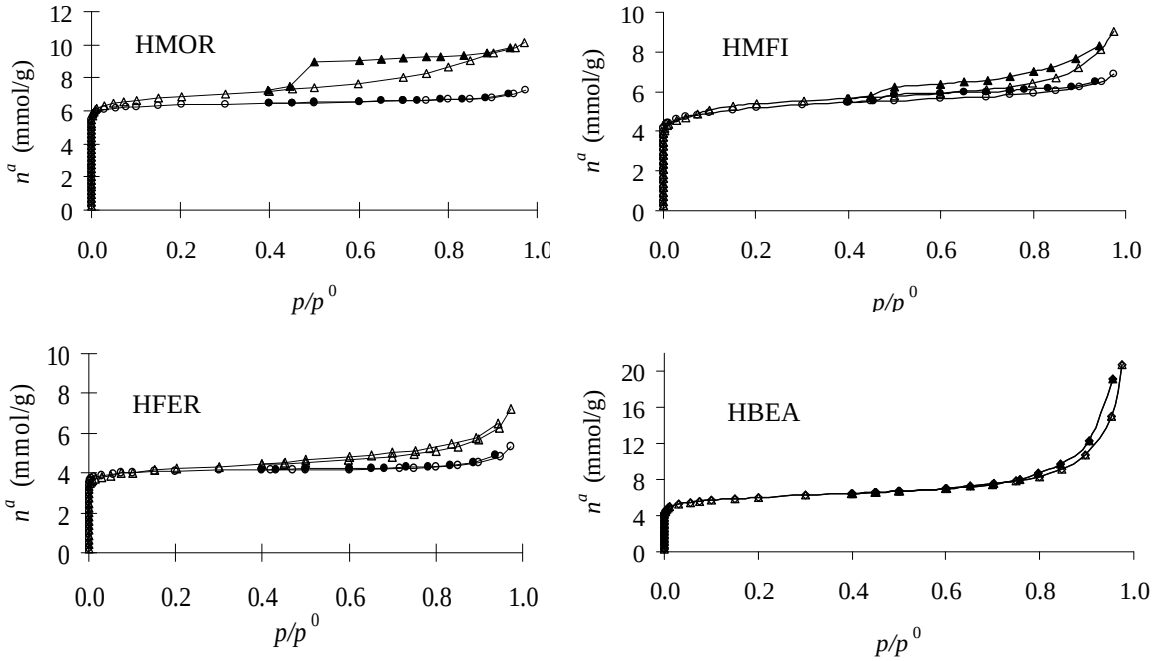

Figure 2 – N_2 adsorption/desorption isotherms at -196 ºC for parent (circles) and alkaline treated (triangles) zeolites. Open and closed symbols represent adsorption and desorption points, respectively.

From adsorption data the micropore (V_{micro}), mesopore (V_{meso}) and total porous volumes (V_T), as well as the external surface area (A_{ext}), were calculated. The results are listed in Table 1, where treated samples are named according with the convention: parent zeolite-des.

Table 1 – Textural properties of the parent and alkaline treated HMOR zeolites; micropore (V_{micro}) by t-method, mesopore (V_{meso}) by subtracting the microporous volumes from the total pore volume at $p/p^0 \sim 0.95$ (V_T) and external surface area (A_{ext}).

Zeolite	V_{micro} (cm^3g^{-1})	V_{meso} (cm^3g^{-1})	V_T (cm^3g^{-1})	A_{ext} (m^2g^{-1})
HMOR	0.21	0.04	0.25	16
HMOR-des	0.19	0.15	0.34	101
HMFI	0.16	0.07	0.23	56
HMFI-des	0.16	0.13	0.29	61
HFER	0.14	0.03	0.17	13
HFER-des	0.13	0.10	0.23	51
HBEA	0.16	0.40	0.56	123
HBEA-des	0.16	0.40	0.56	123

In line with the discussion made by the analysis of the isotherms configuration, the values reported in Table 1 show that, except in the case of BEA, the alkaline treatment lead to an important development of the mesoporosity. For instance, HMOR-des and HFER-des present a V_{meso} more than triple of that observed for the correspondent parent structures. Associated with the mesoporosity development a small fraction of the inherent microporous structure was destroyed. In the most unfavourable case, HMOR, the loss corresponds to only 10 % of the initial microporous volume. It is interesting to note that, in disagreement with the

data reported by Groen *et al.* (2004), the V_{micro} of the HMFI sample did not change after the desilication treatment and curiously this is the structure where V_{meso} showed the smallest increase. The results obtained with BEA were also unexpected because, according to the literature, among all the essayed structures this is the one that should lead to an easiest Si extraction, as a result of both less stable framework and the relatively large interconnected channels, which permits an adequate transport of hydroxyl ions through the channels for hydrolysis of Si-O-Si bonds (Groen, 2004). These results are most likely related with the fact that we used BEA and MFI structures with much smaller Si/Al ratios than those of the structures essayed by Groen *et al.* (2004). In fact, in other study, focused on MFI type zeolites, these authors found out that the mesoporous structure development depends of the framework Si/Al ratio, being particularly important for high values (Groen, 2005). On the other hand, the BEA zeolite used in the present study has a much lower V_{micro} than that of the structure used by Groen *et al.(*2004), suggesting that our sample was less crystalline, what could also influence the desilication process. The mesopore size distribution was made according the Broekhoff-de Boer method, in a version simplified (Lukens, 1999) with the Frenkel-Halsey-Hill equation (BdB-FHH). The very broad size distribution curves obtained (not shown) reveal that the mesopores created upon the alkaline treatment have openings covering all the mesoporosity range.

SEM images of the parent zeolites (Fig. 3) show that in all the cases the crystals are very small. HBEA image reveals not only the presence of the smallest crystallites but also an high degree of aggregation, what justifies the important mesoporous volume detected for this zeolite, that most probably comes from the pores that are formed in the spaces resulting of the crystallites aggregation. The small sizes of the crystallites prevent a global conclusion about morphological changes due to the alkaline treatment. In fact, only in the case of HFER-des a partial dissolution of the outer surface of the crystals could be detected (Fig. 3e).

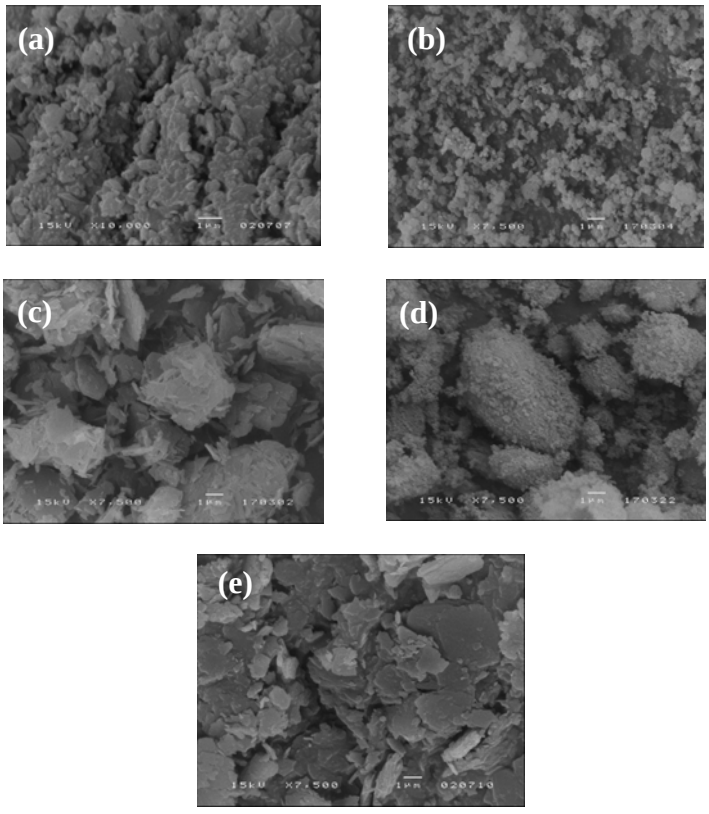

Figure 3 – SEM images of HMOR (a), HMFI (b), HFER(c), HBEA (d), and HFER-des (e).

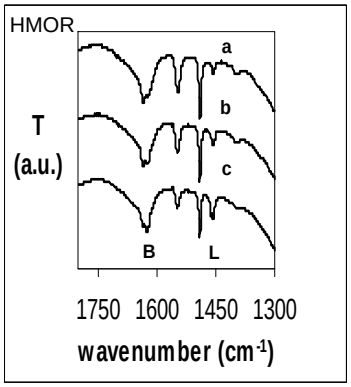
n-Heptane cracking was used as a model reaction to characterize the acidity of the samples and, in this sense, evaluate possible changes in acidity after desilication treatments. The main reaction products are hydrocarbons (olefins and paraffins) with three and four carbon atoms (C_3 and C_4). Some isomerization and aromatization products and also light products, with one and two carbon atoms (C_1 and C_2) are also detected in small amounts. After desilication all samples show identical catalytic behaviour as the parent ones. In Table 2 the main parameters related to n-heptane cracking for the parent and desilicated zeolite samples are quoted.

Table 2 – Main parameters for n-heptane cracking at 350 ºC after 5 min. of time-on-stream.

Sample	Conversion (molar %)	O/P (C_4)	B/L (C_4)	Deactivation (%)
HMOR	31.39	0.2	2.3	85.3
HMOR-des	24.28	0.2	2.7	83.2
HMFI	28.15	0.7	0.9	3.3
HMFI-des	29.36	0.7	0.9	5.7
HFER	1.92	0.8	2.3	43.8
HFER-des	0.92	1.7	0.7	20.7
HBEA	33.90	0.2	4.0	62.7
HBEA-des	39.19	0.2	3.7	50.7

The alkaline treated samples show a slightly lower initial activity but a similar deactivation, except for FER and BEA samples. The olefin/paraffin (O/P) ratio measures the hydrogen transfer ability of the catalysts. An O/P ratio, lower than 1, indicates a consumption of olefins for the formation of heavy carbonaceous compounds during hydrogen transfer reaction (Poutsma, 1976). As this reaction follows a bimolecular mechanism, it is favoured by a high density of acid sites. The O/P ratio remains constant after desilication for all samples, except for HFER-des, where it increases, indicating that in the majority of the cases the acid sites density is not modified. The branched/linear (B/L) ratio is related not only with the catalyst acidity but also with the space available inside the porous structure. HMOR-des is the only sample that presents higher B/L ratio, meaning that the desilication treatment enlarged the zeolite pores, increasing the formation of branched products. This result is in agreement with the textural characterisation, since if we do not consider the unusual values found for BEA samples, this is the sample that presents the highest values of V_{meso} and A_{ext}. The B/L ratio remains practically unchanged after alkaline treatment for HBEA and HMFI catalysts. HFER based samples show a distinct behaviour with very small conversions, indicating the occurrence of catalytic reactions mainly at the external surface, due to difusional limitations inside the narrow porous structure of this zeolite. After alkaline treatment higher O/P and low B/L values are observed, what is in agreement with the partial dissolution of the crystal surface detected by SEM.

Infrared spectra of pyridine after desorption at temperatures between 200 and 400 ºC, in the range 1400-1700 cm^{-1}, are shown in Fig. 4 for HMOR and HMOR-des samples. The interaction between pyridine and the zeolite acid sites results in the appearance of bands characteristic of pyridine adsorbed to Brönsted acid sites around 1544 and 1636 cm^{-1}, to Lewis acid sites at 1622 and 1455 cm^{-1} (Guadurier and Lefebvre, 1988) The presence of both types of acid sites was detected in the parent and in the treated sample. To estimate the relative site population for Brönsted acid sites the integral intensity of the bands characteristic of pyridine coordinated to these centers were normalized against the structure Si-O combination band, at 1860-1800 cm^{-1}. The results are designated as N.I. (normalized integral intensities) and are displayed in Fig. 5.



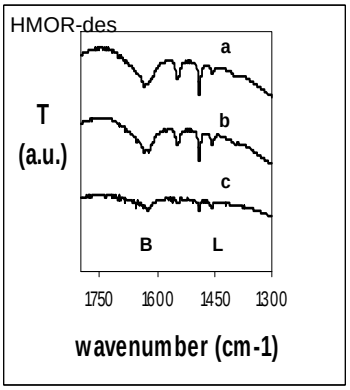


Figure 4 – IR spectra of pyridine adsorbed on HMOR and HMOR-des after outgasing at 200 (a), 300 (b) and 400 ºC (c). B and L indicate the bands related to Brönsted and Lewis acid sites, respectively.

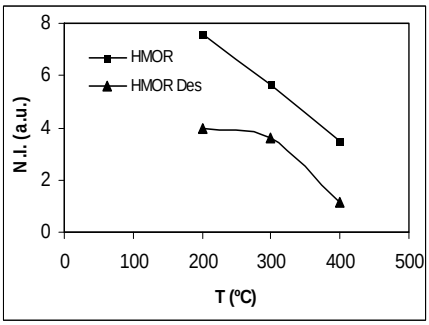

Figure 5 – Normalised integral intensities (N.I.) of pyridine adsorbed on Brönsted acid sites versus desorption temperature.

The estimation of Brönsted site density for HMOR-des shows a decrease of about 50% in all the range of temperature, when compared with the parent zeolite. This result is in agreement with some decrease in conversion observed for the alkaline treated sample in n-heptane cracking. Nevertheless is does not seem to affect the O/P ratio, meaning that the remaining acid sites are enough to ensure the occurrence of bimolecular reactions in the same extent as in the parent material.

Topic:

Abstract

Semi-synthetic beta-lactam antibiotics are the most important class of antibacterial agents. Ampicillin (6-[2-amino-2-phenylacetamide] penicillanic acid) is in the penicillin group of which penicillin proper was the first antibiotic to be used in therapy (Bruggink et al., 2001; Pessina et al., 1988). There is a growing need for developing bioactive implants, due biomaterials are biocompatible, resorbable, and present osteoconductive properties. Advantages of implantable drug delivery tools can include high release efficiency, precise dose control, low toxicity, and allow to overcome disadvantages connected with conventional methods (Uhrich et al., 1999). In this respect, hydroxyapatite (HA) is an elective material. It enables to produce architectures similar to those of real bones. Here we studied a kinetic model to describe ampicillin release from HA. In the course of the release experiment, ampicillin was dissolved in phosphate buffer to make a stock solution, maintained at 30 ºC and shaken at 60 strokes/minute. Samples were withdrawn periodically for analysis and then returned to the mixture. Adsorbed amounts were measured by the difference of the concentration of the antibiotics before and after adsorption using UV adsorption at 225 nm.

1 Introdution

Semi-synthetic beta-lactam antibiotics are the most important class of antibacterial agents. Their use in veterinary and human medicine is in continuous expansion. Some examples of semi-synthetic penicillins and cephalosporins are: amoxicillin, ampicillin, cephalexin, cefadroxil, cefazolin, among many others. They have in common the presence of the beta-lactam ring, responsible for their anti-microbial activity. They irreversibly inhibit the last step of the bacterial cell wall biosynthesis.

The beta-lactam antibiotics can be described in terms of a beta-lactam nucleus with a side-chain (see Figure 1). Many different nuclei and side-chains are found in the antibiotics that are in use today. Different combinations of side-chains and nuclei form antibiotics with distinctive properties; for example, replacing the phenylacetic acid side-chain of penicillin G with D-phenylglycine (PG) results in the beta-lactam antibiotic ampicillin, which in contrast to penicillin G, is orally stable (Cole, 1969; Bruggink et al., 1998; Wegman et al., 2001; Ribeiro et al., 2005). Ampicillin (6-[2-amino-2-phenylacetamide] penicillanic acid) is in the penicillin group of which penicillin proper was the first antibiotic to be used in therapy (Bruggink et al., 2001; Pessina et al., 1988). It is one of most widely used semi-synthetic beta-lactam antibiotics (Ospina et al., 1996). It has an estimated market of 20,000 ton/year (Bruggink et al., 2001).

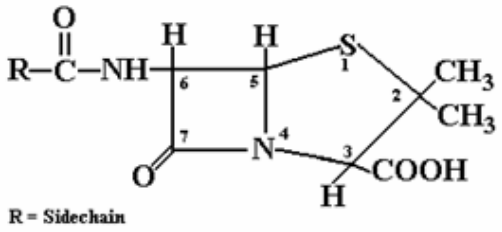

Figure 1: General structure of beta-lactam antibiotics.

There is a growing need for developing bioactive implants, due biomaterials are biocompatible, resorbable, and present osteoconductive properties. It is known that the use of bone substances has many inherent disadvantages in practical applications, and it is linked to many surgical problems (Suchanek and Yoshimura, 1998).

Advantages of implantable drug delivery tools can include high release efficiency, precise dose control, low toxicity, and allow to overcome disadvantages connected with conventional methods (Uhrich et al., 1999). In this respect, hydroxyapatite (HA) is an elective material. It enables to produce architectures similar to those of real bones. Here we studied a kinetic model to describe ampicillin release from HA. HA analogous to the mineral component of bones, its properties make it desirable as implant materials and delivery agents of drugs. This paper describes the ampicillin adsorption and release profiles of HA material. The aim of this work was to evaluate its application as ampicillin delivery carrier.

2 Materials and methods

2.1 Materials

Ampicillin was from Aldrich Chem. Co., USA. All other chemicals were of laboratory grade from different commercial suppliers.

2.2 Antibiotic loaded HA samples

Ampicillin was used as drug molecules. HA were impregnated with 25 mM of antibiotic buffer solution at 30 ºC for 48 h. Ampicillin adsorbed in the HA has been quantified by spectophotometric analysis. In the course of the release experiment, ampicillin was dissolved in phosphate buffer to make a stock solution, maintained at 30 ºC and shaken at 60 strokes/minute. Kinetic experiments to determine the amount of ampicillin adsorbed as a function of contact time were conducted by stirring. Samples were withdrawn periodically for analysis and then returned to the mixture. Adsorbed amounts were measured by the difference of the concentration of the antibiotics before and after adsorption using UV adsorption at 215 nm.

2.3 HA synthesis

HA was synthesized by the aqueous precipitation method from CaO and H_3PO_4 as the reagents, and used as a carrier for charging ampicillin. In this study, apatite nanoparticles were produced by aqueous precipitation. The starting solution was 0.3 M H_3PO_4, 0.5 M $Ca(OH)_2$, 1M CH_3CHCO_2HOH. The pH value of the solution was adjusted to pH 8 by NH_4OH additon. The suspensions were left overnight for ageing. The suspension was then vacuum filtered and washed in deionised water to remove NH_4OH. The powders were dried in an oven at 100 ºC overnight. The powders were analysed by X-ray diffraction (XRD) and then sintered. Sintered powders were again analysed by XRD to assess the final phase composition (Albuquerque et al., 2003).

2.4 Solubility experiments

Solubility of ampicillin was determined following Gude et al., 1996. The samples were prepared gravimetrically. Glass-flasks with screw caps filled with the samples were immersed

into a thermostated water bath and stirred. All samples were stirred for at least 4 h. Subsequently, the mixture was allowed to settle. The samples were taken with syringes with an attached 0.2 μm filter to avoid entrainment of solids. The compositions of the liquid phases were analyzed by HPLC.

2.5 Analysis

Concentrations of ampicillin were determined using HPLC to analyze if antibiotic degraded during the assays: C18 column (Waters Nova-Pack, C18, 60 Å, 4 μm, 3.9 × 150 mm); eluent: 35% acetonitrile, 2‰ SDS (lauryl sodium sulphate), 10 mM H3PO4, 5 mM K2H2PO4, with a flow of 1 mL/min at 25 °C and λ = 225 nm.

2.6 Adsorption performance:

Ampicillin adsorption performance (*AP*) was defined as follows:

$$\%AP = \left(1 - \frac{C^*}{C^{initial}}\right) \times 100$$

Where *C** is the concentration of ampicillin (mM) and, $C^{initial}$ is the concentration of ampicillin at the beginning of the assays (mM).

3 Results

3.1 Solubility Studies

The solubility of ampicillin was measured for pHs in the range 7.0-8.0, at 30ºC. The selected range of pHs for the solubility studies was bracketed by stability of antibiotic. The obtained results, which are shown in Figure 2, are similar to the ones obtained by other authors (Diender et al., 1998; Rudolph et al., 1999; Youshko et al., 2000).

Ampicillin solubility increases with the pH. This behavior can be explained by its determined values of the acid group pK (2.66) and amine group pK (7.24) and calculated of its isoelectric point (4.95). Hence, above the pH correspondent to its isoelectric point the number of ampicillin molecules with a neutral charge (which is the most insoluble form) decreases, leading to higher solubility values. This effect becomes more important for pH above 7.0.

Our aim is to perform the ampicillin adsorption with its separation from HA at 37ºC, what implies to working at sorption conditions where the solubility of AMP is the highest possible. Therefore, the obtained results indicate that for higher pH the performance of the ampicillin release might be better. However, the best value for pH is a trade-off between AMP solubility and temperature.

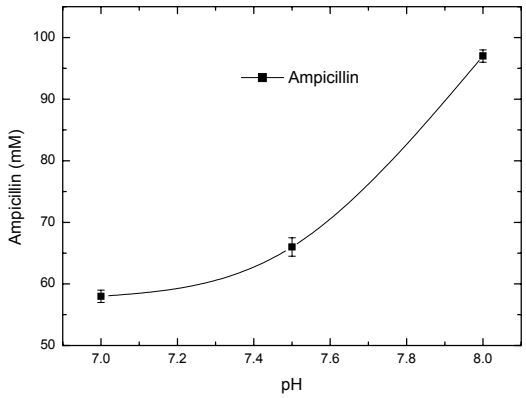

Figure 2: Solubility of ampicillin as function of pH at 30ºC.

Temperature effects on the solubility of all compounds were also evaluated by determining the compounds solubility at pH 7.0 and 8.0, at 37ºC. The antibiotic solubility slightly increases at 37ºC. Most of the solubility values at 37ºC were around 11% higher than

those at 30ºC. However, operation of the system at 37ºC implies to much lower adsorption rates than at 30ºC. It is believed that a increase of 11 % in the ampicillin solubility is not big enough to justify the operation at such a high temperature. Anyway, these experiments aimed at only indicating the range of adsorption conditions for studying the kinetic of the process.

3.2 Equilibrium time

In order to properly evaluate the adsorption process of ampicillin, the equilibrium curves were determined experimentally. Equilibrium time depends on adsorption rate, i.e., affinity between antibiotic and HA and, temperature of assay. Figure 3 shows the results to ampicillin adsorption at 30 and 37 ºC, respectively. It can be observed that equilibrium state was obtained at 8 hour. At 37 ºC, adsorption rate higher than at 30 ºC can be explained due to increasing of mass transfer, because adsorption is not favor at higher temperatures.

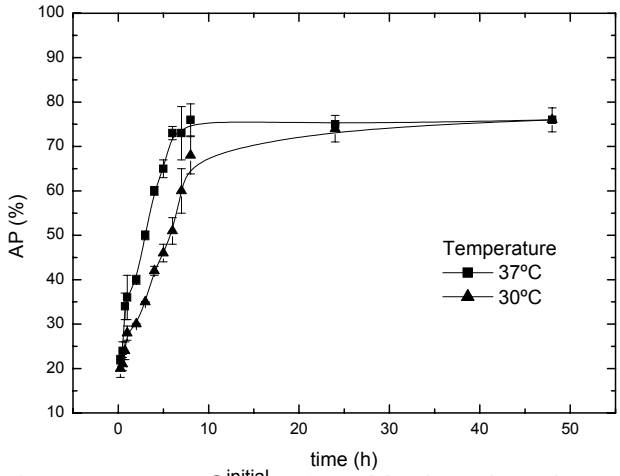

Figure 3: Equilibrium assays at $C^{initial}$ = 25 mM, phosphate butter 10 mM, pH 7.5.

3.3 pH effect at adsorption isotherms

Figure 4 shows the effect of pH at adsorption performance of ampicillin. It can be observed that AP decreases when pH increases. The amino group of ampicillin is not protoned when pH increases, so less antibiotic can be adsorbed on HA. Therefore, ampicillin adsorption slightly improves when pH decreases.

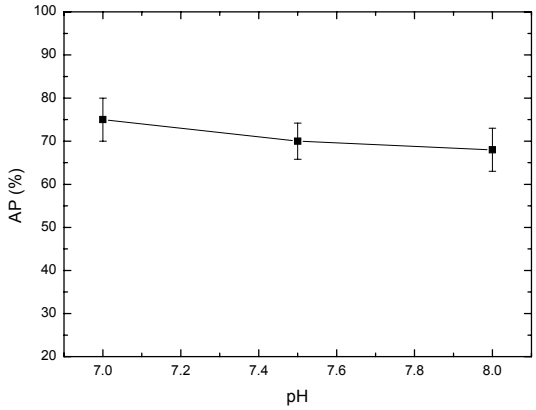

Figure 4: pH effect on adsorption ampicillin at 30 ºC.

Adsorption isotherms of ampicillin on HA at 30 ºC and pH 7.0 were shown in Figure 5. The adsorption isotherms were further correlated to the Freudlich equation:

$$q = KC^{1/n}$$

Where *q* is the equilibrium adsorption capacity (mg/g_{HA}), *C* is the initial concentration of ampicillin (mg/mL), *K* is the Freundlich parameter and, *n* is the Freundlich parameter related to the magnitude of adsorption driving force. Some assumptions were made to adsorption model: the process operated under isothermal conditions, HA porosity was constant and homogeneous along as the particle. The data plotted according to the Freundlich isotherm were K = 52.51 ± 3.48, n = 1.758 ± 0.036 and, R^2 = 0.980. The results indicate that Freundlich isotherm can represent the isotherm data of HA appropriately in the given concentration range.

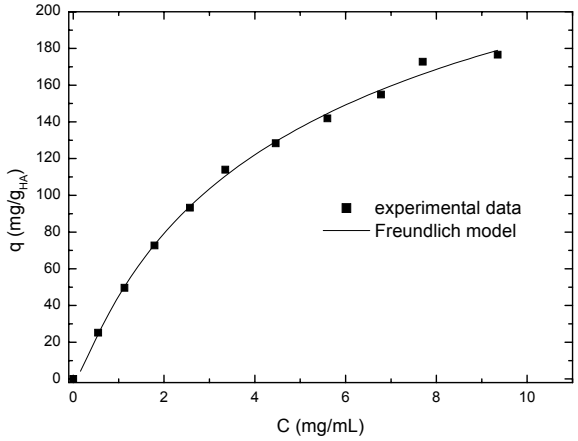

Figure 5: Adsorption isotherm of ampicillin on HA at 30 ºC, pH 7.0

4 Conclusions

Ampicillin solubility was studied at different pH. Higher pH improved ampicillin solubility. The equilibrium state was obtained at 8 hour of assay. At 37 ºC, adsorption rate was higher than at 30 ºC. The best results of adsorption performance were obtained when pH decreased (7.0). The relation between the adsorption capacity and the equilibrium solute concentration was analyzed. Freundlich isotherm was used and provided good fit for data.

Solvent Effect on the Antioxidant Activity of Extracts of *Myrtus communis* L. leaves

Idalino Manuel Costa Faísca, M. Gabriela Bernardo-Gil*, José Abecassis Empis, M. João Cebola, Paula Gomes Pereira

Centre for Biological and Chemical Engineering, IBB, DEQB, IST,
Av. Rovisco Pais, 1049 – 001 Lisboa, Portugal

Keywords**:** Myrtle, *Myrtus communis*, antioxidant activity, extraction, Rancimat
Topic: Multi-scale and/or multi-disciplinary approach to process-product innovation

Abstract

Myrtle (*Myrtus communis* L.) leaves, from plants originated from the Centre region of Portugal, were subjected to different treatments to obtain extracts with antioxidant activity.

The sample leaves were submitted to hydrodistillation (Clevenger distillation) and the deodorised solid residues were solvent extracted. The solvents tested were hexane, diethyl ether, isobutyl acetate, ethyl acetate, acetone, isopropyl alcohol, butanol, ethanol, and methanol. The largest extract yields were obtained with methanol, followed by ethanol.

The antioxidant activity of the extracts was evaluated by Rancimat against the sunflower oil. All the extracts presented very high protection factors (PF), the highest being the extract obtained by using ethyl acetate (PF = 2.58). When both the yields and the PF were compared, the isopropyl alcohol extract presented the best values (PF = 1.8; Yield = 25 g extract / 100 g deodorised solid residue).

1. Introduction

Oxidative stress is involved in the pathogenesis of numerous diseases. On the other hand, lipid oxidation is responsible for deterioration of fats and oils resulting in colour, flavour and nutritive value changes. One of the main practices in order to retard oxidation is the addition of antioxidants in fats and fatty foods and cosmetics. The antioxidants can be of synthetic or natural origin. The use of synthetic antioxidants is restricted in several countries, because of their undesirable long-term toxicological effects, including carcinogenicity (Gazzani *et al.*, 1998). For instance, butylated hydroxytoluene (BHT) had little effect on mutagenicity at low concentrations, but significantly increased their mutagenicity at high concentrations (Shahidi and Wanasundara, 1992). A number of studies have reported that BHT may cause internal and external haemorrhaging at high doses that is severe enough to cause death in some strains of mice and guinea-pigs (Chen *et al.*, 1992). As a result, there is a great interest in finding antioxidants from natural sources for food and medicinal applications.

Extracts obtained from herbs and spices have been found to present antioxidant activity, and their use instead of synthetic antioxidants is becoming increasingly popular. Several works show that the majority of antioxidant active substances occur in extracts, but some essential oils were also studied to analyse their antioxidant activity, namely essential oil containing thymol and carvacrol, and other phenolic compounds, which exhibit high antioxidative activity. Esquível *et al.* (1999) evaluated the antioxidant

activity of savoury extracts. Ribeiro *et al.* (2001) studied the antioxidant activity in supercritical fluid extracts residues. Reddy *et al.* (2005) determined the antioxidant activity of amla, drumstick leaves, and raisins. Rubilar *et al.* (2006) evaluated murta leaves as a source of antioxidant polyphenols. Pellegrini *et al.* (2007) studied the efficiency of extraction of a sequence of solvents of some fruit and vegetable foods, in order to evaluate their antioxidant capacity. Ali *et al.* (2007) studied several Indian medicinal herbs as sources of antioxidants. Yanishlieva *et al.* (2006) presented a review with results on the stabilization of lipids and lipid-containing foods with different herbs and spices (ground materials and extracts). Although many plants has been investigated, only rosemary and sage are commercially available as flavourless, odourless, and colourless antioxidant extracts.

Myrtle (*Myrtus communis* L.) belongs to the Myrtaceae family. It is an evergreen shrub which grows wild in the Mediterranean area under different conditions of light availability that has been used since ancient times for medicinal, food and spice purposes (Mendes *et al.* 2001). The leaves contain tannins, flavonoids such as quercetin, catechin and myricetin derivatives and volatile oils, the fruits are mostly composed of volatile oils, tannins, sugars, flavonoids and organic acids such as citric and malic acid, and leaves and fruits have been used as an antiseptic and for healing wounds as well as in the treatment of urinary diseases, in folk medicine. The essential oil is also important in perfumery (Cakir, 2004). Tuberoso *et al.* (2006) determined the compositions of essential oils and alcoholic extracts of myrtle leaves and berries collected in Sardinia (Italy), and Jamoussi *et al.* (2005) studied the effect of harvest time on the yield and composition of Tunisian myrtle oils. Messaoun *et al.* (2005) showed that there is strong variability of the essential oil composition in natural populations of *Myrtus communis* in Tunisia. Farah *et al.* (2006) studied the effect of fractional distillation on the chemical composition of Moroccan myrtle essential oils.

Owing to the differing antioxidant potential of compounds with different polarities in complex whole foods, all methods for assessing the antioxidant activity of food samples are strongly affected by the solvents that were used during extraction (Pellegrini *et al.*, 2007). Romani, Pineli *et al.* (1999), and Romani *et al.* (2004) identified polyphenols in leaf extracts of *Myrtus communis* L. Demo *et al.* (1999) used hexane to obtain extracts of several plants including myrtle, and they found that their antioxidant activity could be correlated to the α-tocopherol content. Appendino *et al.* (2002) obtained extracts from myrtle by using acetone, and observed that the extracts presented strong antioxidant activity. Silva *et al*. (2007) studied the extraction of phenolics from *Inga edulis* leaves by using different proportions of the mixture ethanol + water, at various temperatures and at several liquid-to-solid ratios.

There are several methods for the evaluation of antioxidant action on fats and oils (Frankel and Meyer, 2000; Becker, Nissen and Skibsted, 2004). The Rancimat method has some advantages such as a quick answer, and allowing the stability evaluation at high temperatures, which are important factors for the use of the antioxidants in food processing. Dessi *et al*. (2001) studied the antioxidant activity of methanol extracts from several plants growing in Sardinia, having used the oxidation of linoleic acid as oxidation trials. Pizzale *et al.* (2002) studied the antioxidant activity by using the Rancimat apparatus of methanolic extracts of sage and oregano.

The objective of this work was to obtain extracts from the solid residues of the hydrodistillation of myrtle leaves, by using several solvent, and to study their antioxidant activity.

2. Materials and Methods

Materials

Wild myrtle was collected in the Centre of Portugal region, at pre-floral and post-floral stages. Leaves were naturally air-dried in darkness. The remaining humidity was 12.3 %. Before extraction, leaves were milled. The particle diameter after size reduction was

determined by using a Retsch KS 1000 sieving machine, the medium particle dimension being calculated as 0.8 mm.

Standards were purchased from Sigma Aldrich, and all the other chemicals were obtained from Merck, at the highest purity available.

Extraction of essential oils

The essential oils of *Myrtus communis* were obtained by using a modified Clevenger apparatus during 3 hours. The amounts of recovered oils were measured gravimetrically.

Solvent extraction

The solid residues of Clevenger distillation were used for preparation of extracts with eventual antioxidant activity, by using two solvent extraction methods: solid-liquid extraction at solvent boiling temperature with the solid immersed in solvent, and Soxhlet method. Hexane (Hex), diethyl ether (Diet), isobutyl acetate (iBtAc), ethyl acetate (EtAc), acetone (Acet), isopropyl alcohol (iPrOH), butanol (BtOH), ethanol (EtOH), and methanol (MeOH) were used as solvents. After the extraction, the solvent was evaporated by using a rotary evaporator (Heidolph VV2000).

Analysis of essential oils

The essential oils were analysed by gas chromatography on a Hewlett-Packard 5890 Series II chromatograph equipped with a FID detector and a DB5 column (5% phenyl, 95% dimethylpolysiloxane), 0.32 mm id x 50m, film thickness 0.17 μm. The column temperature was programmed to hold at 60 ºC for 10 minutes, then heated to 180 ºC at a slope of 2 ºC/min, with a final isothermal hold at 180 ºC for 30 minutes. Injector and detector temperatures were 200 and 250ºC, respectively. Carrier gas, N_2 was adjusted to a linear velocity of 2 ml/min. The samples were injected using the split mode (split ratio 1:20) being the injection volume 0.2 μl.

The sample components were identified by comparing the retention times with those of chromatographic standard of the compounds. Peak areas were determined using a Hewlett-Packard 3396 Series II integrator. For quantitative analyses, the peak areas were converted to absolute values using response factors estimated from the standard compounds. Results were compared to those obtained by GC-MS.

Rancimat method

The Rancimat method is commonly used to evaluate the antioxidant activity of extracts and is based on the increase of electrical conductivity due to the formation of volatile dicarboxylic acids as a result of lipid oxidation. Metrohm Rancimat 679 was used.

Samples of extract were dissolved in 7.0 g of sunflower oil, so that the concentration in extracts was 5000 ppm, and were heated at 110 ºC. A continuous air stream (20 L/h) was passed through the heated samples, and the volatile compounds were absorbed in a conductivity cell. Conductivities were continuously monitored until a sudden rise signified the end of induction period. Protection factors were determined by the ratio between the induction period found for the sunflower oil with a certain quantity of extract and the induction time obtained for sunflower oil with no addition of extract.

3. Results and Discussion

In Table 1 components of myrtle essential oils (EO) obtained from plants harvested in Centre – Portugal (sample 1 – pre-floral and sample 2 – post-floral) are presented. Results are medium values of five replicates.

The main components are 1,8-cineole followed by α-pinene and myrtenyl acetate. No evident differences occurred between compositions of pre-floral and post-floral myrtle leaves essential oils.

Table 1. Chemical composition (wt %) of *Myrtus communis* essential oils

Compound	Sample 1	Sample 2
α-Tujene	0.18	0.15
α-Pinene	33.5	34.1
Camphene	0.06	-
β-Pinene	0.32	0.29
Myrcene	0.09	0.09
α-Phellandrene	0.34	0.34
α-Terpinene	0.12	0.14
p-Cymene	0.14	0.04
Limonene	13.1	9.74
1,8-Cineole	25.4	26.7
Camphor	0.05	0.07
γ-Terpinene	0.16	0.14
Terpinolene	0.09	0.13
Linalool	3.91	6.62
Linalyl acetate	0.36	0.53
Cis-Verbenol	0.10	-
Terpinene-4-ol	0.12	0.16
α-Terpeniol	1.44	2.33
Borneol	0.51	0.53
Myrtenol	0.22	0.37
Nerol	0.04	-
Geraniol	0.40	1.03
Tymol	0.10	0.17
Myrtenyl acetate	5.74	9.84
Methyl eugenol	0.10	0.34
Eugenol	0.04	0.09
Geranyl acetate	0.72	1.71
Verbenone	0.83	1.42
β-Caryophyllene	0.08	0.27
α-Humulene	0.04	0.16
Iso-eugenyl acetate	0.17	0.39
Caryophellene oxide	0.14	0.20

In Figure 1, the extraction yields obtained from solid residues of hydro-distillation, with different solvents, at 2h of extraction time are presented. The higher yields were obtained for extracts obtained by using Soxhlet apparatus, when alcohols were used as solvents, and the highest was obtained with methanol (29.8 %), but similar values (about 26 %) were obtained by using ethanol, butanol and iso-propanol. Pizzale *et al.* (2002) obtained yields of about 20 % and 26 % when methanol was used to produce extracts of *Sage officinalis* and *Sage fruticosa*, respectively.

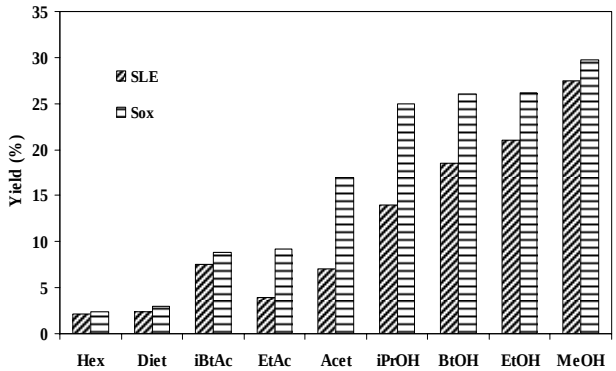

Fig. 1. Extraction yields obtained from solid residues of hydro-distillation, with different solvents, after 2h of extraction time. SLE – solid-liquid extraction at solvent boiling temperature with the solid immersed in solvent; Sox – Soxhlet method.

Protection Factors of extracts obtained from solid residues of Clevenger distillation of sample 2, at 2h of extraction time, with different solvents, are presented in Figure 2. The extraction method did not affect significantly the antioxidant activity of the extracts. The higher values of protection factors were obtained with solvents of intermediate polarity, such as ethyl acetate (PF=2.58) and diethyl ether (PF=2.23). However, alcoholic extracts also presented high antioxidant activity.

Silva *et al*. verified that the high values of phenolics contents were obtained by using the mixture ethanol + water, 86.8 % (v:v), at 58.2 ºC. The protection factors obtained by Pizzale *et al.* (2002) for methanolic extracts of sage and oregano are of the same magnitude of methanolic extracts of Myrtle obtained in this work.

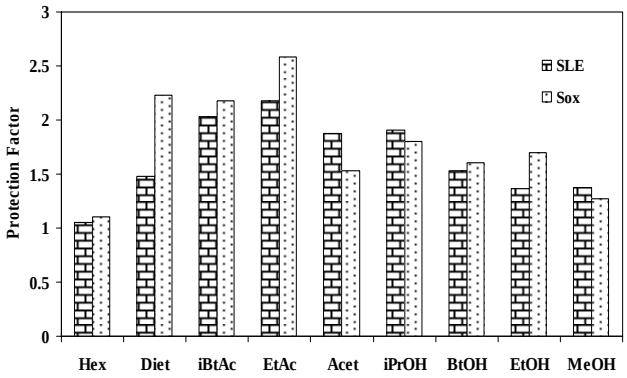

Fig. 2. Protection Factors of extracts (5000 ppm, total extract) obtained from solid residues of hydro-distillation, with different solvents, after 2h of extraction time. SLE – solid-liquid extraction at solvent boiling temperature with the solid immersed in solvent; Sox – Soxhlet method.

When both the yields and the protection factor were compared, the best solvent was isopropyl alcohol (yield = 25 % and PF = 1.8).

Conclusions

The obtained results shows that *Myrtus communis* leaves have a high potential for the production of extracts with high antioxidant activity.

Deodorised solid residues were extracted by using several solvents, and the results point towards the alcohols as being the solvents producing the best yields. But a good yield does not mean that the solvent is selective. And that seems to be what is happening with the alcohols, because when observing the results of the antioxidant activity, the best protection factors were obtained with ethyl acetate and diethyl ether, although alcoholic extracts also evidenced high antioxidant activity.

When both the yields and the protection factor were compared, the best solvent was the isopropyl alcohol.

Selection of a suitable adsorbent for decoloring sugar solutions from beet industry with ion exchange resins

M. Teresa García*, Mónica Coca, Silvia Mato, Irene Mediavilla, Gerardo González

Univ. Valladolid, Dep. Chemical Engineering and Environmental Technology, Pº Prado de la Magdalena s/n, 47011 Valladolid, Spain.

Keywords: Sugar technology; Color removal; Melanoidins; Resins; Size exclusion chromatography
Topic: Food Engineering

Abstract

Decolorization processes based on ion exchange resins have been applied for removing colorants present in sugar beet thin juices, in order to obtain a higher quality juice, without colored impurities that may reduce the efficiency of the crystallization stage. Molecular size distribution of coloring impurities in sugar beet juices was also studied to follow the evolution of colorants during the decolorization process. The color reduction percentages achieved were about 84-87% using decolorization processes based on one single stage. No considerable differences were observed between styrenic and acrylic resins. Dry matter content, purity and pH remained virtually constant during the decolorization process. The color reduction percentages slightly increased up to 91-92% using two beds in series. Size exclusion chromatography (SEC) of sugar beet thin juices confirmed the presence of colorants with molecular masses of 100-50 kDa and 2-3 kDa. The colorants with molecular mass of 100-50 kDa were completely removed whereas components 2-3 kDa presented lower removal efficiencies, showing lower affinity for the resins, especially for the acrylic resin.

1 Introduction

Juices and syrups formed during sugar beet processing contain impurities that impart yellow or brown color to white sugar. The origins of colorants are very diverse. These compounds are mainly formed through beet processing as a result of sugar degradation reactions, pH changes, thermal effects and reactions between amino compounds and carbohydrates (Maillard reaction). Despite their small quantities, colorants have a great impact on sugar quality. High molecular weight colorants may be occluded within sugar crystals, causing a negative effect on quantity and quality of white sugar. To meet standards of whiteness, it is necessary to undertake efforts to reduce color levels in the end product. The use of sulphur dioxide that inhibits non-enzymatic browning reactions or the adsorption with activated carbon is some of decolorization methods employed in industry. However, at usually process pH conditions, the colorants in beet sugar juices are mainly anionic compounds that may be removed by adsorption using ionic exchange resins (Broughton et al., 1991; García Agudo et al., 2002). Acrylic resins are commonly used to decolorize refined sugar solutions. These resins show low adsorption selectivity but can be easily regenerated. Polystyrenic resins show high decolorization efficiencies but its regeneration is more difficult than acrylic resins. The extent of adsorption of colored impurities depends on their molecular weight, type of charge, pH and character hydrophobic/hydrophilic (Bento, 1997). Most of resin applications in decolorization have been made in cane sugar industry (Bento, 1992, 1997; Godshall,

* Corresponding author. Tel +34 983 423 166; Fax: +34 983 432 013; E-mail: maite@iq.uva.es.

1999). Decolorization by ion exchange resins has not been employed in the beet sugar industry to the same extent as in cane sugar processing. The aim this work was to remove colored compounds present in sugar beet thin juice. Styrenic and acrylic resins were used in order to select a suitable decolorization scheme based on a single bed or two resin columns placed in series. Analysis by size exclusion chromatography coupled with diode array detection was chosen to yield information about the evolution of high molecular weight colorants in the decolorization stage.

2 Material and Methods

- *Adsorbent*: Three resins have been tested: the strong styrenic resins Lewatit S 6368 and Lewatit S 6328 A (Bayer) and the acrylic resin Lewatit VP OC 1074. Prior to being used, resins were regenerated with sodium hydroxide (4%w/w) and then washed with distilled water.
- *Adsorbate*: Sugar beet solutions containing 17-18% dry matter, pH 8.5-9.0, purity 96-97% and 3000-3300 IU were used in all experiments. Sugar solutions were prepared by diluting thick juice from a Northern beet sugar factory in Spain**.**
- *Experimental set up*: Experiments were carried out in duplicate in jacketed columns operating in parallel. Each column held 207 mL of resin (1 Bed Volume). Decolorization experiments were performed at 60 ºC feeding the thin juice at a flow rate of 11 BV/h in down flow direction. The cycle length was prolonged up to reduce about 90% of color. Decolorization was followed measuring absorbance at a wavelength of 420 nm, according to ICUMSA methods (ICUMSA, 1994). Two decolorization procedures were studied. First, decolorization in one bed (styrenic or acrylic resin) and then, decolorization in two beds connected in series. Two different types of resins were used in the columns. The experimental setup is shown in Figure 1.

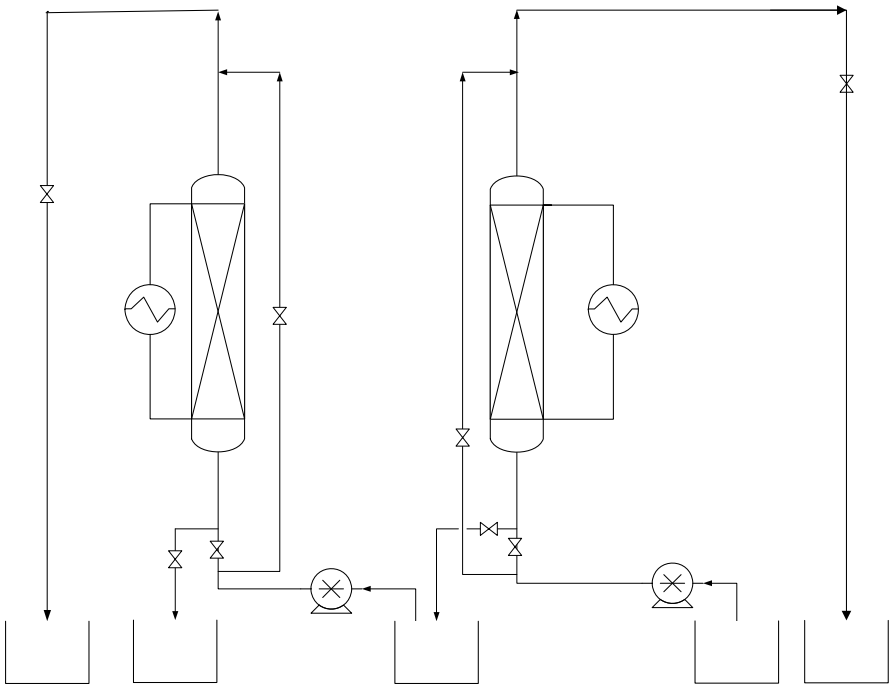

Figure 1: Experimental set up. Decolorization using two adsorbents in series.

After decolorization, resins were washed with 9 BV/h of distilled water in up flow mode until the outlet stream had almost no sugar in solution (0 to 1% dry matter). Resin regeneration was achieved with an alkaline calcium saccharate (Bento, 1999) solution containing $CaCl_2$ (25 g/L), CaO (5 g/L) and sucrose (120 g/L). Regenerant was fed

through the resin in down flow at 2.3 BV/h and 60 ºC. Finally, the resin was washed with distilled water at 9 BV/h in up flow mode until a value of dry matter content in the effluent lower than 5%. Washings were performed at room temperature. All the experiments were carried out in duplicate and mean values are presented.

- *Analytical procedures*: Color, dry matter content, pH and purity were determined according to ICUMSA methods (ICUMSA, 1994). The molecular masses of colored compounds were estimated by size exclusion chromatography (SEC). Separation was achieved in an Ultrahydrogel™ 250 column. Identification was achieved by using a Waters 996 Photodiode Array Detector. Samples were filtered through a 0.22 μm membrane before injecting onto the column.

3 Results and Discussion

Decolorization experiments were carried out feeding 5.5 BV (bed volume) at 11 BV/h. The volume of regenerant was 6.9 BV, fed during 180 min for achieving the release of adsorbed colorants. Table 1 compares the mean decolorization percentages attained using one decolorization bed or two decolorization beds in series. Color load adsorbed was calculated according to references (Bento, 1997).

Table 1: Decolorization efficiencies using ion exchange resins.

Resin	Decolorization, %	Adsorbed color load, %
S 6328A	84.4 ± 2.7	84.7 ± 2.7
S 6368	87.1 ± 3.8	88.6 ± 2.2
VP OC 1074	87.0 ± 0.1	87.4 ± 0.1
VP OC 1074 + S 6368	91.8 ± 0.8	95.3
S 6368 + VP OC 1074	91.5 ± 1.5	95.5

Dry matter content, purity and pH remained almost constant during the experimental runs. From the experimental results shown in Table 1, it can be concluded that there were no considerably differences among the resins studied. The styrenic resin S6368 provided slightly higher color removal percentages, a mean value about 87.1% was obtained, which corresponded to an adsorbed color load about 88.6%. As can be seen from Table 1, the decolorization percentages slightly increased using two beds in series. The acrylic resin followed by the styrenic resin (S 6368) provided the higher decolorization percentages, about 91.8%, which an adsorbed color load of 95.3%. The combination styrenic-acrylic resins provided a similar color reduction percentage, 91.5%.

Size exclusion chromatograms (Figure 2) showed that the colorants of higher molecular masses, 100-50 kDa, were more efficiently removed than the colorants of lower molecular weigh (about 2-3 kDa). As can be seen in Figure 2, colorants of higher molecular masses were almost completely removed whereas the reduction of 2-3 kDa colorants was considerably lower. Colorants of higher molecular mass are likely to be related to melanoidins (Coca et al., 2004). SEC chromatograms also confirmed that both styrenic resins were more efficient in removing lower molecular weight colorants than the acrylic resin VP OC 1074.

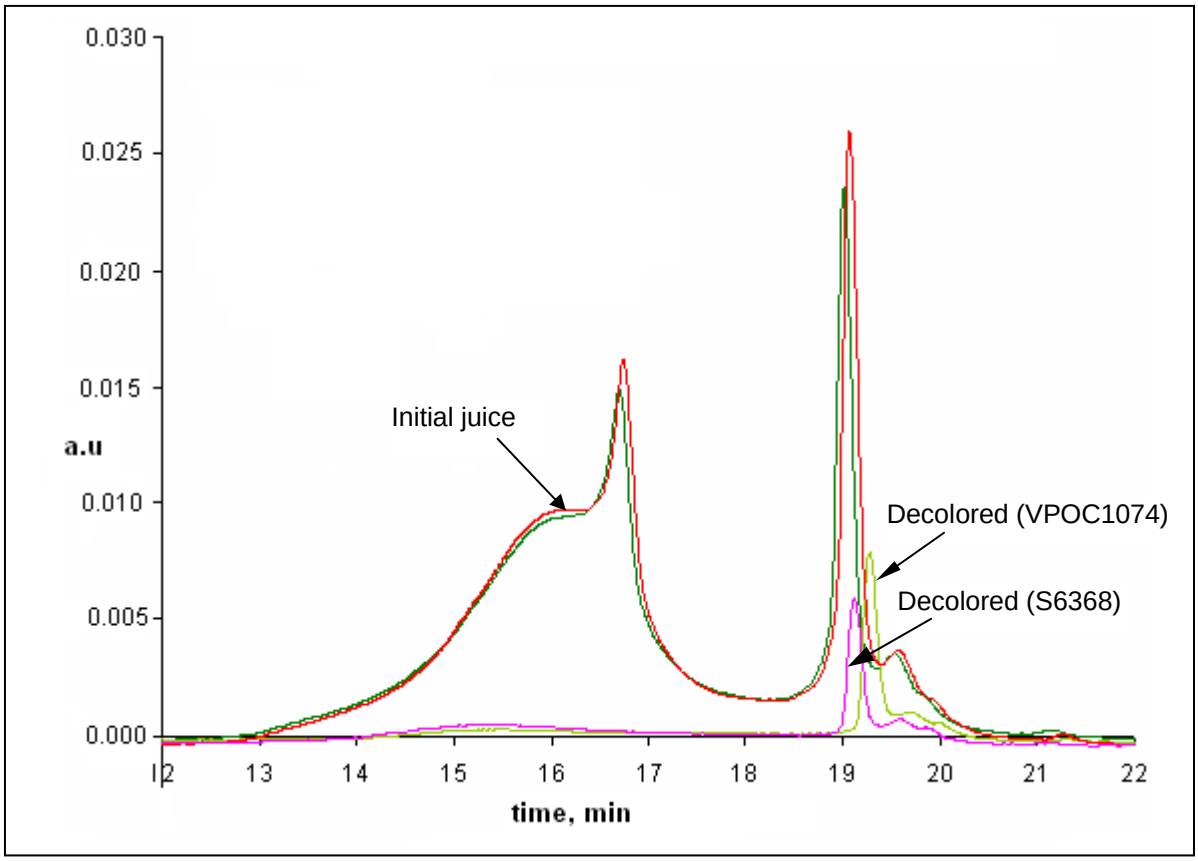

Figure 2: Decolorization of thin juice. Chromatograms run at 420 nm; a.u. absorbance units

4 Conclusions

In this work, a decolorization process using ion exchange resins has been studied for removing colored impurities in sugar solutions. The experimental results showed that decolorization using ion exchange resins is a suitable process for removing high molecular weight colorants in thin juices. The styrenic and acrylic resins tested showed similar results. Decolorization using two beds in series did not increase considerably the color reduction percentages. However, ion exchangers suffer the disadvantage of requiring regeneration. Therefore, this study must be improved with an optimization of the regeneration stage regarding the reduction of chemicals consumption and effluent disposal.

Kinetics of Kraft Pulp Brightening with Hydrogen Peroxide in a Final ECF Stage

Pedro E.G. Loureiro[1*], Dmitry V. Evtuguin[2], M. Graça V.S. Carvalho[1]

Topic: Advancing the chemical and biological engineering fundamentals

Abstract

An industrial ECF partially bleached kraft pulp (DED) was further bleached in the laboratory with a final hydrogen peroxide stage in order to study its brightening kinetics. DTPA was used as additive since the preliminary study showed its usefulness on reducing peroxide consumption and on preserving pulp intrinsic viscosity. A novel approach was used to separate the peroxide consumption in pulp brightening reactions from the amount wasted in decomposition reactions. A negative effect of temperatures higher than 70 ºC was observed on peroxide decomposition, reaching half of its total consumption at 90 ºC. Furthermore, residence times greater than 120 min are not advisable for temperatures greater than 70ºC.

1 Introduction

Elemental chlorine free (ECF) sequences are presently the most used technology in wood pulp bleaching. The consolidation of this multistage pulp bleaching technique still needs better coordination between bleaching stages and target brightness, enhanced flexibility and higher washing efficiency, within the so-called concept of minimum impact mill. Regarding eucalyptus bleached pulps, there is an ever-increasing market demand, mainly for printing and writing paper grades. These specific products demand high strength pulps bleached to high brightness levels and exhibiting low brightness reversion. In this context, the final bleaching stage plays a key role in determining the quality of a market end-product.

The final stage in a chemical pulp bleaching sequence is a truly brightening stage to gain the difficult brightness points with the destruction of the chromophores remaining in pulp. The origin of many of these chromophores has been recently assigned to quinone type structures (Rosenau et al., 2007), thus justifying the final bleaching stage with hydrogen peroxide, which degrades these kinds of structures. Under alkaline conditions the brightening agent is considered to be the hydrogen peroxide anion (HOO^-), a strong nucleophile that reacts preferentially with carbonyl and conjugated carbonyl groups (Lachenal, 1996). However, besides chromophores destruction, the waste of hydrogen peroxide in decomposition reactions should be also considered. These competitive reactions are rather complex being base- and metal-catalysed. They involve distinct pathways, being water, oxygen and the intermediates hydroxyl ($HO\cdot$) and superoxide anion ($O_2\cdot^-$) radicals, the decomposition products. The reactions catalysed by transition metals, such as Mn, Fe and Cu, are the most detrimental due to the production of unselective radical species that can attack polysaccharides, thus reducing the pulp quality and/or yield. That is why a hydrogen peroxide bleaching stage always needs a metals control in the bleach plant which is carried out by using a previous selective chelation stage in a dedicated tower or by an unselective acid wash stage. The use of magnesium (as $MgSO_4$), which counteracts the detrimental effect of the transition metals, and/or chelants (e.g., EDTA and DTPA) as additives in the peroxide stage is common as well.

The replacement of the final chlorine dioxide stage (D) in a conventional bleaching sequence, such as DEDD, by a hydrogen peroxide stage (P) is now well recognized to be advantageous in terms of pulp beatability and paper quality, with a particular emphasis on a lower brightness reversion (Parthasarathy and Colodette, 2007, Carvalho et al., 2008; Loureiro et al., 2008a). Accordingly, this shift in the last stage demands a kinetic study to find the optimal conditions to run the final P stage and also to provide a comprehensive comparison of the brightening and decomposition reactions rates, which is the aim of this paper. Our ultimate goal will be the development of mathematical kinetic models that could ensure efficient process control and optimization in a mill situation and, whenever possible, some mechanistic insights on reaction phenomena.

2 Experimental

An industrial sample of *Eucalyptus globulus* kraft pulp was collected in a conventional ECF bleach plant, DEDED, before entering in the last stage. The DED pulp was then thoroughly washed in the laboratory. This pulp had an ISO brightness of 87.5% and an intrinsic viscosity of 1066 dm^3/kg. In a preliminary study, the best stabilizing system was studied by using $MgSO_4$ and the sodium salt of diethylenetriaminepentaacetate (DTPA) and ethylenediaminetetraacetate (EDTA) as additives - Table 1. As for the kinetic studies, the pulp was bleached with hydrogen peroxide according to the conditions summarized in Table 1, at the reaction times of 1, 5, 15, 30, 60, 120, 180 and 240 min. The components of the bleaching system were pre-heated in an agitated thermostatic water bath to the desired temperature, as follows: the pulp was mixed with DTPA and NaOH solutions at 13% consistency in a polyethylene bag; in a glass flask, the H_2O_2 solution was added to the equivalent amount of water needed to attain a final consistency of 10%. After the pre-heating period, the hydrogen peroxide solution was added to the pulp suspension, setting the beginning of the reaction. The hydrogen peroxide decomposition kinetics were studied also according to the conditions in Table 1, using a highly bleached pulp (ISO brightness of 93.4 %) produced with the same DED pulp by applying a P stage twice at 8.0% odp H_2O_2, 1.1% odp NaOH, 0.05% odp DTPA, 90ºC for 60 min, with standard pulp washing in between.

Table 1. Ranges of bleaching conditions used in the final P stage.

Bleaching variable*	Preliminary study	Kinetic study
H_2O_2 (% odp)	1.0	0.5 – 2.0
NaOH (% odp)	0.60	0.6 – 0.8
DTPA (% odp)	0.05-0.20	0.05
EDTA (% odp)	0.05-0.20	---
$MgSO_4$ (% odp)	0.025-0.100	---
Temperature (ºC)	70	60 – 90
Time (min)	30	0 – 240

* - odp – oven dried pulp; consistency: 10%; 20 g of pulp (on a dry basis) were used in all experiments.

After each batch experiment, the pulp was vacuum filtered and the collected filtrate was used for the determination of chemicals residuals after its cooling in an ice bath. The pulp was also cooled with distilled water (~4ºC) and then washed with three litres of distilled water (~35ºC) divided into three equal portions. Hydrogen peroxide residual was determined by iodometric titration with standardized sodium thiosulphate solution while sodium hydroxide residual was determined by titration until pH 8.6 with standardized hydrochloric acid solution after barium chloride addition and filtration.

The ISO brightness and intrinsic viscosity were measured according to ISO 2470 and ISO 5351, respectively. Handsheets for optical properties determination were prepared using the standard procedure described in ISO 3688. The pulp metals content was determined by

atomic absorption spectroscopy in accordance with TAPPI T266-om. All the experimental procedures were performed twice and the results presented are the mean values.

3 Results and Discussion

The results of the preliminary study about peroxide stabilization are presented in Table 2. The positive effects of the additives on peroxide consumption, pulp ISO brightness and pulp intrinsic viscosity confirms their importance towards an economical and efficient brightening response. In fact, for the same ISO brightness level of 90±0.5%, the hydrogen peroxide consumption is much higher when no additives are introduced, as well as the loss in the viscosity, compared to the other bleaching systems. The reduction on peroxide consumption is most significant with DTPA, being a small charge of 0.05% odp quite enough. This is linked to the well established role of the transition metals on catalysing hydrogen peroxide decomposition reactions. Therefore, the results show that these competitive reactions can be minimized if efficient additives are introduced in the stage. The calcium, magnesium, iron and manganese contents of some bleached pulp samples is depicted in Figure 1. The use of chelants (EDTA and DTPA) led to a reduction in transition metals content, in particular Mn, which is the most detrimental ion in catalyzing hydrogen peroxide decomposition. The highest values of the Mg/Mn ratio, greater than 170 (much higher than the critical value of 30), are reached with the use of DTPA alone (both charges) or combined with $MgSO_4$ and with the use of EDTA+$MgSO_4$. Therefore, in the following kinetic studies a DTPA charge of 0.05% odp was used.

Table 2. Effect of different stabilizing systems on the performance of the final P stage of a $DE_{OP}DP$ bleaching sequence.

Additive charge (% odp)			DEDP pulp		
$MgSO_4$	DTPA	EDTA	H_2O_2 consumed (%)	ISO brightness (%)	Intrinsic viscosity (dm^3/kg)
---	---	---	42	90.2	979
0.025	---	---	21	89.9	1002
0.100	---	---	31	90.0	1056
---	0.050	---	9	90.1	1051
---	0.200	---	9	89.8	1065
0.025	0.050	---	15	89.9	1018
0.100	0.100	---	19	89.9	1049
---	---	0.050	22	90.0	1000
---	---	0.200	15	89.7	1001
0.025	---	0.050	14	89.9	1050
0.100	---	0.100	19	89.7	1035

The pulp ISO brightness evolution throughout the bleaching process is presented in Figures 2 and 3. In all experiments, there is a fast brightness gain in the first minutes of reaction which slows down afterwards. In some cases, asymptotic levels are attained and in others a negative evolution is even observed. These results suggest that a kinetic model to be developed may comprise two phases with different kinetics parameters due to the presence of chromophoric structures with dissimilar reaction rates. The brightness evolution is faster as hydrogen peroxide charge and/or the temperature increases. The moderate temperature of 70ºC renders a continuous evolution of brightness values for several hydrogen peroxide charges. In fact, even with the lowest charge, a brightness ceiling is not attained (Figure 2). Although an initial higher development of pulp brightness as temperature raises is observed (Figure 3), for temperatures greater than 70ºC, all hydrogen peroxide is consumed after

nearly 60 min (Figures 4 and 5) which leads to a slight pulp darkening for longer times. Therefore, 70ºC – 80ºC is a recommended range for the pulp used and residence times greater than 120 min are not advisable for greater temperatures. The recommended value is quite lower than the optimum reported in related literature, 90 ºC (Anderson and Amini, 1996). However, as shown in a complementary study (Loureiro et al., 2008b) the brightening kinetics of a final P stage strongly depends on pulp history, therefore no straightforward conclusions can be drawn without mention the pulp nature.

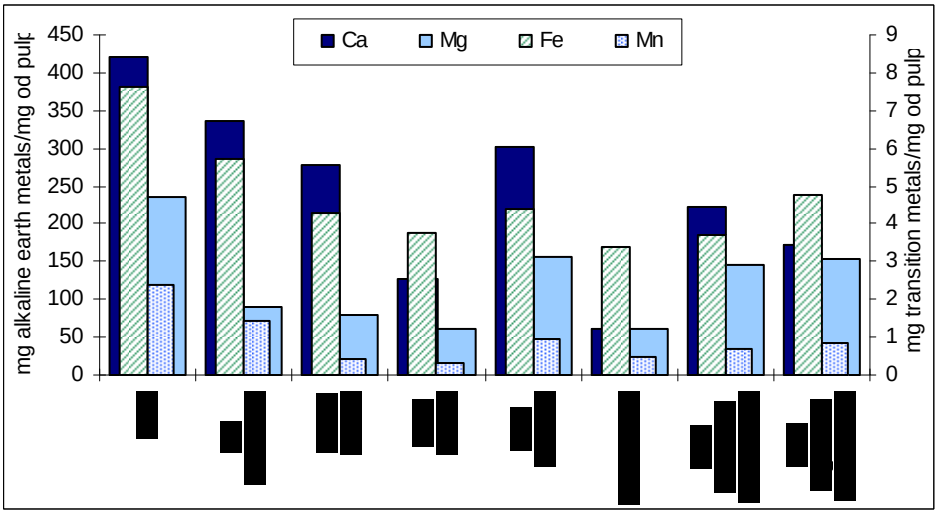

Figure 1. Ca, Mg, Fe and Mn contents of the $DE_{OP}DP$ bleached pulps using different stabilizing systems in the final P stage.

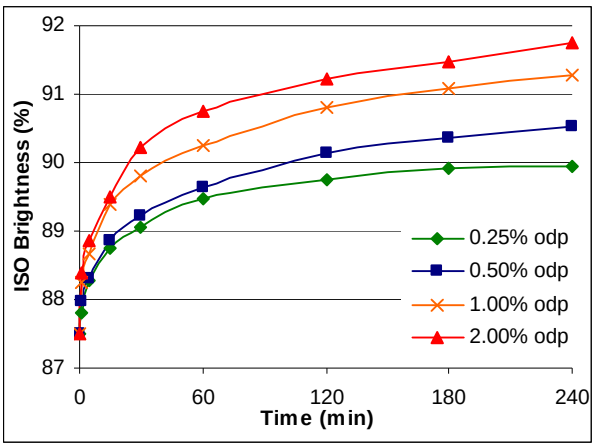

Figure 2. Brightening kinetics at 70 ºC with different hydrogen peroxide charges.

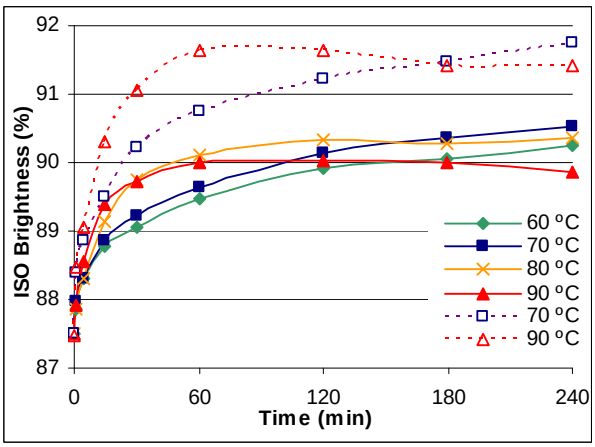

Figure 3. Effect of temperature on the brightening kinetics. H_2O_2 charges of 0.5 (filled symbols) and 2.0 % odp (empty symbols).

In terms of sodium hydroxide consumption, a continuous trend is seen only for temperatures greater than 70 ºC, while at 70 ºC the profile is by floors - Figures 6 and 7. Its consumption increases with temperature.

To assess the hydrogen peroxide consumed in the parallel reactions, other than brightening reactions, the same industrial pulp was used but bleached to very high brightness (with negligible chromophores content). A comparison between the total hydrogen peroxide consumed in the final P stage and the fraction consumed in decomposition reactions is presented in Figures 8 and 9 where a strong dependence on the temperature is perceived.

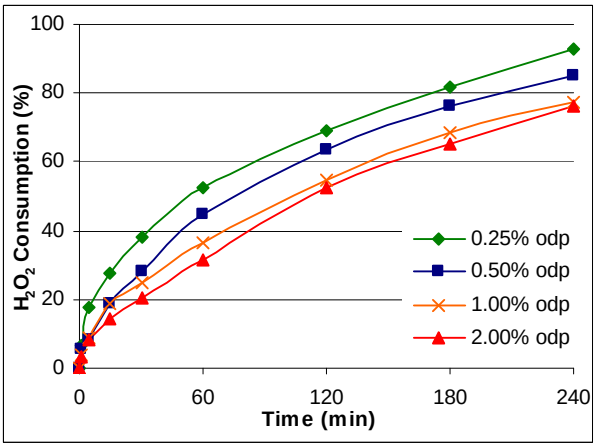

Figure 4. Hydrogen peroxide consumption kinetics at 70 ºC with different H_2O_2 charges.

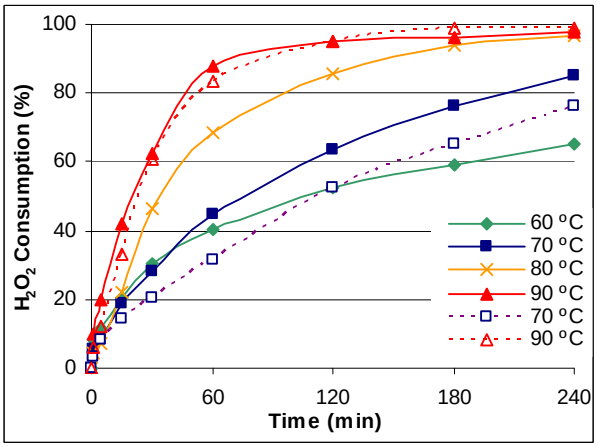

Figure 5. Effect of temperature on H_2O_2 consumption. H_2O_2 charges of 0.5 (filled symbols) and 2.0 % odp (empty symbols).

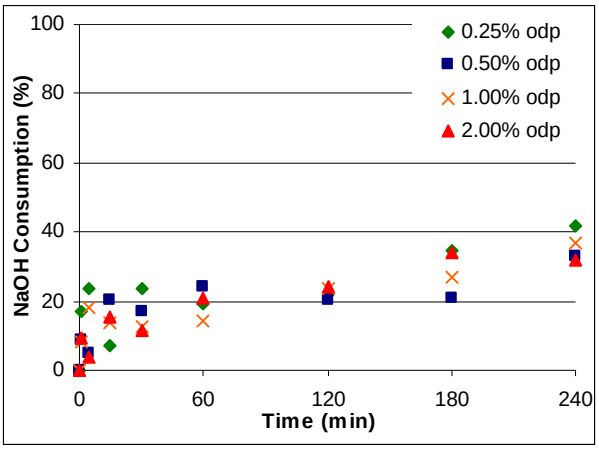

Figure 6. Sodium hydroxide consumption kinetics at 70 ºC with different H_2O_2 charges.

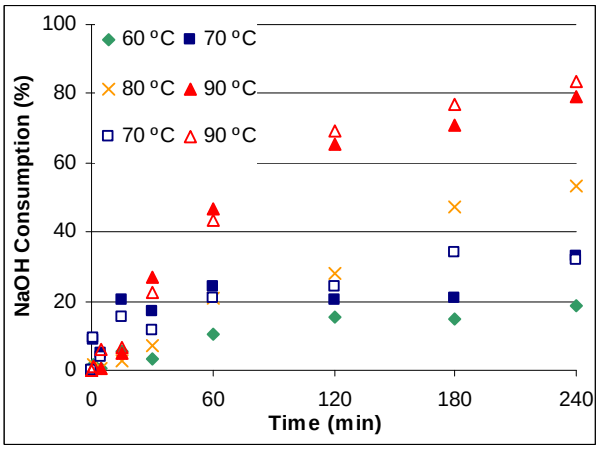

Figure 7. Effect of temperature on sodium H_2O_2 kinetics. H_2O_2 charges of 0.5 (filled symbols) and 2.0 % odp (empty symbols).

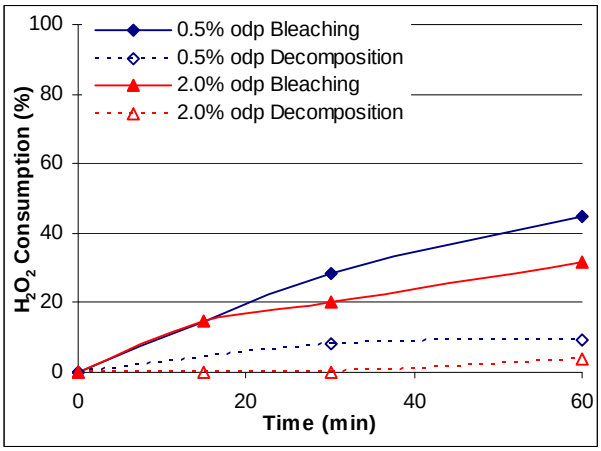

Figure 8. Comparison of H_2O_2 decomposition kinetics with total consumption kinetics in the P stage at 70 ºC with different H_2O_2 charges.

.

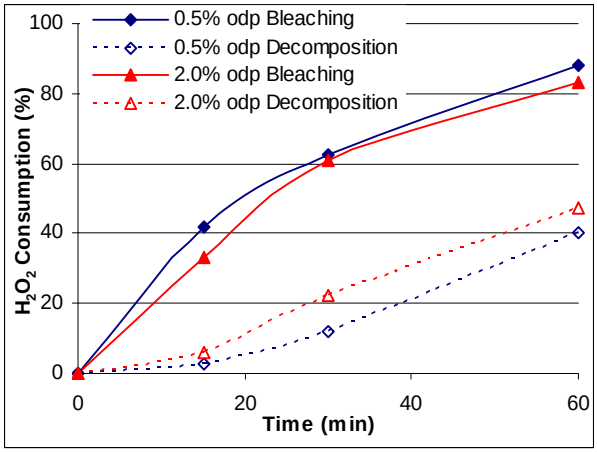

Figure 9. Comparison of H_2O_2 decomposition kinetics with total consumption kinetics in the P stage at 90 ºC with different H_2O_2 charges.

.

At 70ºC the H_2O_2 decomposition is minimal while at 90ºC the rate is enhanced. At 90ºC, the ratio between both consumptions increases with reaction time in favour of decomposition, reaching after 60 min near 50%, which is therefore wasted in non-brightening reactions.

In an earlier work by Stevens and Hsieh (1997), using an oxygen delignified softwood kraft pulp post-chelated, the peroxide decomposition was measured in a different way by monitoring the pressure rise in a CRS reactor. However, the majority of the experiments were conducted at very low consistency (0.5%) and keeping constant the chemicals concentration. In their additional experiments at 5 and 10% consistency, they did not find significant differences in the pulp brightness and peroxide consumption, despite being difficult to keep a medium homogeneous using a stirred reactor at such higher levels of consistency. Nevertheless, they also pointed out that the rate of decomposition is substantially increased at high temperatures, mostly under transition metal catalysis. Even with the addition of DTPA in our trials, it is expected that at high temperatures its metal trapping efficiency is impaired, not avoiding decomposition reactions.

4 Conclusions

It is important to minimize transition metal catalyzed reactions through the use of efficient additives in the final P stage, otherwise hydrogen peroxide is wasted in non-brightening reactions and at the same time impairing pulp intrinsic viscosity. A low charge of DTPA was quite enough to fulfil these requirements, at least at 70ºC. Residence times greater than 120 min are not advisable for temperatures greater than 70ºC for the pulp used.

Comparing the hydrogen peroxide decomposition kinetics with total peroxide decomposition kinetics, it was shown the importance of temperature in the decomposition rate. At 90ºC it reached half of the total hydrogen peroxide consumption after 60 min of reaction.

Topic: Environmental engineering & management or Sustainable & clean technologies

Abstract

The use of alkaline industrial effluents as liquid absorbents is an attractive solution for flue gases treatment, when both currents are produced in the same plant.

The present work studies the removal of CO_2, SO_2 and NO from mixtures with similar composition to those of flue gases. The experimental essays were performed in a bubble column (inside diameter of 0.14 m, total height of 0.70 m), operated in counter current flow, at atmospheric pressure and ambient temperature. Two different types of absorbents were used: an alkaline industrial effluent and synthetic alkaline aqueous solutions (Na_2CO_3:NaOH).

The main conclusions were that both the industrial and the synthetic alkaline effluents with maximum pH of 12.6 were effectively neutralised to 7.0 < final pH <9.5, the removal values of CO_2 from the gaseous current were up to 25% and SO_2 was completely removed. The absorption of NO, significantly less effective, still claims further work.

1 Introduction

Fossil fuels combustion remains one of the greatest threats for air pollution. As energy demand keeps growing, environmental concerns increase and legal restrictions are more and more exigent. This justifies all the research work made within last decades in order to improve the efficiency of technologies used for the abatement of pollutants produced by fossil fuels combustion. All measures taken to improve the efficiency of combustion units are of prime importance for emissions reduction and good results are obtained with those preventive strategies in many power generation units. However, even in these cases, the removal of pollutants in flue gases by end of line technologies is normally necessary to meet legal standards.

Special attention has been devoted to the removal of SO_x, NO_x and more recently CO_2, due to its effect on global warming. Wet scrubbing, semidry and dry processes for SO_x removal, selective non-catalytic or catalytic reduction of NO_x are used for emissions treatment. Costs associated with these technologies are significant, mainly for the budget of small and medium size industrial units. Absorption processes used to eliminate acid gases from flue gases are widely described in the literature as wet scrubbing. They are considered the most efficient for SO_x removal, but usually more expensive. The equipment includes spray towers, plate columns or packed towers. Bubble columns are not fully explored. Typical absorbents are aqueous solutions of lime, limestone and sodium carbonate. Simultaneous removal of NO_x is less efficient but recent developments brought new results.

The selection of integrated procedures that take the industrial process as a whole is a quite recent concept. The replacement of common absorbents by alkaline effluents produced in

* Corresponding author. Tel + 351 228 340 500. E-mail: imp@isep.ipp.pt

situ is an attractive solution, as the neutralisation of both currents may be accomplished in a single step. In many industries (Portuguese industrial plants included) both kind of effluents are effectively produced. This study was designed under this perspective, bearing in mind the optimisation of absorption processes. This is considered in the literature an important aspect to be developed.

In the frame of this project and with the objective of studying real cases, a privileged cooperation protocol was established with an industrial Portuguese company: Group PORTUCEL SOPORCEL (Plant of Cacia, Aveiro, Portugal).

2 Experimental procedure

A schematic drawing of the experimental setup is presented in figure 1. The experiments were performed in a bubble column (1, in Figure 1) with inside diameter of 0,14 m and total height of 0,70 m. The column was operated in counter current flow at atmospheric pressure and ambient temperature (16±2ºC), with partial liquid recirculation. The liquid, coming from a feed tank (2, in Fig.1) was dispersed at the top of the column. The approximate volume of liquid in the column was 7 litres, in each experiment, and the total liquid average flowrate in the column was 200 L/h, with 80% recirculation. The gas entered the bottom of the column either through a perforated plate (with 24 holes of 5 mm diameter and one central hole of 2 cm diameter, PP) or through a perforated tube (with 9 holes of 2 mm diameter; PT2 or of 3 mm diameter, PT3).

As gaseous phase, mixtures of CO_2 and air were tested, as well as gaseous mixtures simulating flue gases composition. For these, two synthetic calibrated gas mixtures were used, one containing SO_2, NO and N_2 and the other CO_2, O_2 and N_2.

Experiments were carried out at different total gas flowrates (between 200 and 360 cm^3/s, 20ºC, 1bar) and different gas compositions ($8\%<CO_2<12\%$, $0<SO_2<980ppmv$, $0<NO<720ppmv$).

For every experiment, gas and liquid flowrates were regulated and measured inline (4 and 5 in fig. 1). The pH of the liquid outlet was monitored during each experiment. Except for the initial set of experiments, where the gaseous mixture only contained CO_2 and air, the gas composition at the inlet and outlet of the column has been continuously monitored by means of a gas analyser (Horiba PG 250, 6 in figure 1), in terms of O_2, SO_2, NO_x and CO_2. Data were acquired and stored by means of the analyser software.

All experiments were run until a stable value of pH in the column liquid outlet was reached. At this time, the gas analyser (when used) also provided stable values for the column gas outlet composition.

In a first set of experiments, an industrial effluent from Cacia paper pulp plant ($10.2<pH<11.7$, total alkalinity between 1.2 and 1.6 g $CaCO_3$/L) was used as the liquid phase. Being an industrial effluent, it showed some variability of pH and other characteristics in different dates of sampling. To minimize these differences, the industrial effluent was collected in Aveiro plant and transported to Porto (60 km) in large quantities (300 L or more) so that the largest number of experiments could be performed with no significant change of liquid properties. From these experiments, it was possible to characterize the absorption behaviour of the effluent, for a set of operating conditions.

To overcome the difficulties found with experimental reproducibility and effluent availability, and in order to simplify the experimental planning, the following step was to select a synthetic effluent with similar behaviour to that of the industrial one. Some aqueous solutions of Na_2CO_3:NaOH (in different proportions, meq/L, total concentration of 1.5 g/L as $CaCO_3$) were tested for the same experimental conditions as the industrial effluent.

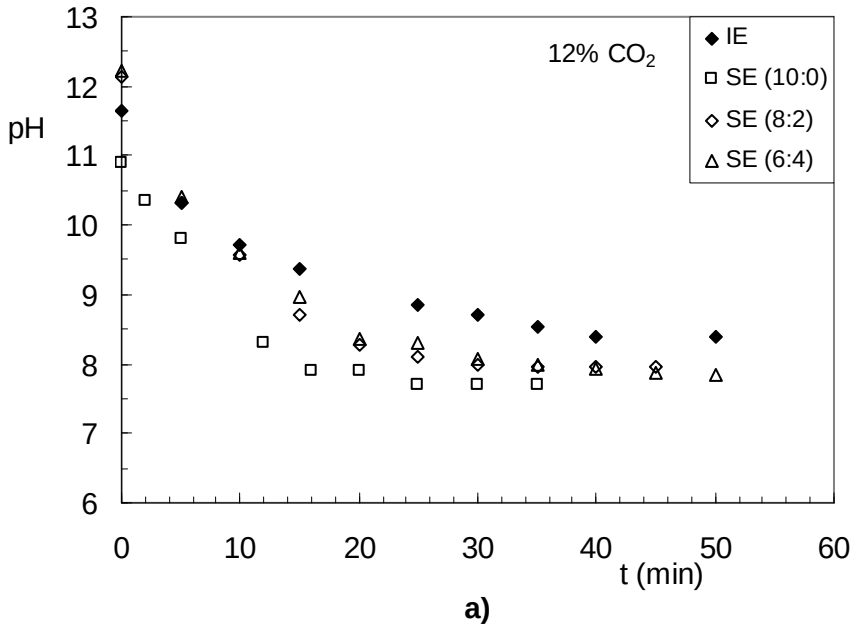
3 Results and discussion

Industrial effluent absorption behaviour and selection of a synthetic effluent

The results presented in figure 2 were obtained for a total gas flowrate of 200 cm^3/s (1bar, 20ºC), using the perforated plate (PP) as gas distributor, and for two different inlet gas compositions (12% and 8% CO_2 in air).



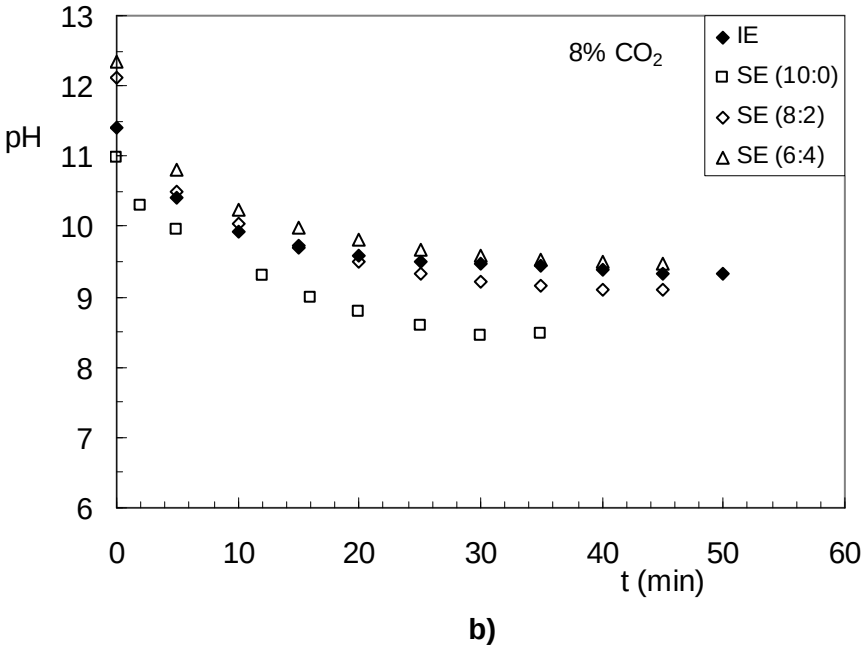


Figure 2 – Evolution of pH in the liquid column outlet with time, for absorption experiments with two different CO_2-air mixtures (a) 12% CO_2; b) 8% CO_2), where industrial effluent (IE) or synthetic effluent (SE) with 3 different proportions (meq/L) of Na_2CO_3:NaOH (1.5 g/L as $CaCO_3$) were used (total gas flowrate: 200 cm^3/s, 20ºC, 1bar; total liquid flowrate: 200 L/h; liquid purge: 42 L/h)

From figure 2, it may be observed that the neutralisation of the industrial effluent (initial pH around 11.5) was accomplished in both experiments, with final pH values of 8.4 (12%CO_2) or 9.3 (8% CO_2).

A similar behaviour was found when the gas phase included SO_2 and NO (9.0% CO_2, 714 ppmv NO, 975 ppmv SO_2). For these experiments, the industrial effluent used had an initial pH of 10.5, leaving the column, in final steady state conditions, with a pH of 7.0.

When comparing the behaviour of the industrial effluent (IE) to that of the synthetic effluents (SE), in both graphs of figure 2, the conclusion is that for the 3 proportions Na_2CO_3:NaOH tested, the one that better approximates the IE behaviour is the 6:4. This concentration was selected to continue the absorption study.

At this stage of the experimental work, the gas analyser was not yet available. Quantifying the removal of CO_2 from the gas phase was only possible by a liquid phase balance to the CO_2 in solution. The validity of this analytical method would be tested later in time, by comparison with gas balance results. The values obtained show that the removal percentages calculated by the liquid balance are systematically higher than those obtained by the gas balance, and with significant differences mainly for high initial values of pH of the liquid. Due to these discrepancies, the only conclusion about CO_2 removal for all the conditions tested (200 < total gas flowrate < 360 cm^3/s, 20ºC, 1bar, 8% < inlet CO_2 < 12%), in this first set of experiments (where CO_2-air was used), the percentage removed from the gaseous current was always less than 17%.

Absorption experiments using typical flue gas compositions

In table 1 some results of CO_2 removal efficiencies are presented, using gas compositions similar to those of flue gases. The CO_2 removal efficiency (as % of inlet CO_2) was calculated from a gas balance, based on the measured values of the gas inlet and outlet composition, in steady state conditions, and on the measured value of the inlet gas flowrate. The outlet gas flowrate was not experimentally measured but could be estimated, from the other known parameters.

Table 1 – Values of CO_2 removal efficiency, for different types of gas distributor, different gas flowrates and compositions; absorbent: aqueous solution of Na_2CO_3:NaOH (6:4, in meq/L), 1.5g/L as $CaCO_3$; liquid flowrate: 200 L/h

Inlet gas phase						Liquid phase		CO_2 removal efficiency (% of inlet)
Gas distributor*	Total gas flowrate (cm^3/s, 20ºC, 1bar)	CO_2 (%)	SO_2 (ppmv)	NO (ppmv)	O_2 (%)	inlet pH	outlet pH	
PP	272	9.40	416	326	9.20	12.0	7.9	14.8
PP	302	9.45	373	291	9.25	11.9	7.7	13.0
TP3	201	8.84	974	714	8.56	12.0	9.5	24.7
TP3	266	9.30	474	348	9.00	12.4	8.4	18.6
TP3	302	9.37	398	292	9.07	12.3	8.0	16.9
TP2	201	8.84	974	714	8.56	12.1	9.0	24.1
TP2	266	9.30	474	348	9.00	12.1	8.0	20.5

*PP – perforated plate; TP3 – perforated tube with 3mm holes; TP2 -– perforated tube with 2mm holes

The results of table 1 show that the perforated tubes allow higher CO_2 removals, without a significant difference between the two (TP2 and TP3), for identical flowrates. For the same gas distributor (TP3, TP2 or PP), the higher values of CO_2 % removal efficiency are obtained

for the lowest gas flowrate. This is probably due to a predominance of the effect of gas contact time in the column, when compared to the effect of higher turbulence for higher gas flowrates. For smaller flowrates, it also may be expected that the specific surface area might be somewhat higher as smaller bubbles are formed.

For the other relevant pollutants, SO_2 and NO, the removal efficiencies were calculated in a similar way. SO_2 was completely removed, as expected. For NO, the percentual removals varied between 0 and 16%.

4 Conclusions

Both the industrial and the synthetic alkaline effluents were effectively neutralised to 7.0< final pH <9.5.

An aqueous solution of Na_2CO_3:NaOH (6:4, in meq/L) with total concentration of 1.5 g/L as $CaCO_3$ was found to reproduce very reasonably the behaviour of the industrial effluent with pH of 11.5 and total alkalinity around 1.5 g/L as $CaCO_3$.

The efficiency values for the removal of CO_2 from the gaseous current were up to 25% (related to the inlet). SO_2 was completely removed, for every experiment and the absorption removal efficiency for NO was not higher than 16% and still claims for further work.

Influence of nitrogen oxides on ozone concentrations at urban and remote areas

Sofia I.V. Sousa*, Maria C. Pereira, Fernando G. Martins, Maria C.M. Alvim-Ferraz

LEPAE – Laboratory for Process, Environmental and Energy Engineering, Department of Chemical Engineering, Faculty of Engineering, University of Porto, Rua Dr. Roberto Frias, s/n, 4200–465 Porto, Portugal.

Keywords: ozone, nitrogen oxides, urban area, remote area
Topic: Sustainable process-product development through green chemistry— Environmental engineering & management.

Abstract

High concentrations of near-surface ozone are known to have negative impacts on human health, especially among risk groups such as persons with respiratory problems, children and elderly. The purposes of this work were to compare ozone concentrations at remote areas with urban ones influenced by traffic and to evaluate how nitrogen dioxide influences ozone concentrations in both, urban and remote areas. For that, the concentrations of ozone and of its precursors at remote areas were assessed and compared with those observed at an urban area influenced by traffic. Measurements using passive samplers were compared with those performed with continuous monitors and it was possible to conclude that measurements with passive samplers had satisfactory reproducibility and precision. Comparing with one urban site, the results obtained at remote sites showed significantly lower concentrations of nitrogen dioxide (12 to 20 times) and volatile organic compounds (2 to 8 times) and higher ozone concentrations (2 to 3 times). It was inferred that the lower concentrations of nitrogen dioxide had determinant influence on the higher ozone concentrations found at the remote sites.

1 Introduction

High concentrations of superficial ozone have negative impacts on human health, vegetation, materials, climate and atmosphere composition (WHO, 2000). It is a particular threat to both, people suffering from respiratory problems, especially children and elderly, and those who exercise outdoors. Health effects include reduced pulmonary function, pulmonary inflammatory processes and increased airway permeability. Long-term exposure to high levels of ozone may lead to irreversible effects on lung function (WHO, 2005). Considering the harmful effects of this pollutant, standards that should not be exceeded were legislated by the European Union: i) information threshold (IT) - 180 $\mu g\ m^{-3}$ (1-hour average); ii) alert threshold (AT) - 240 $\mu g\ m^{-3}$ (1-hour average); and iii) target value for the protection of human health (TVPHH) - 120 $\mu g\ m^{-3}$ (8-hour running average) (EC Directive, 2002).

It is currently accepted that tropospheric ozone is a problem of international dimension, being one of the most important atmospheric pollutants for the twenty-first century (EEA, 1998). Five main factors control tropospheric ozone levels: i) photochemical production; ii) chemical destruction; iii) atmospheric transport; iv) surface dry deposition on vegetation, water and other materials; and v) stratospheric-tropospheric exchanges. In rural areas, ozone is removed mainly through dry deposition, whilst in urban areas the chemical destruction has the most important role (Sienfeld and Pandis, 1998).

Photochemical ozone is formed by reactions involving solar radiation and anthropogenic pollutants (methane, non-methane volatile organic compounds, carbon monoxide) in the presence of nitrogen oxides.

Ozone concentrations are strongly influenced by meteorological factors and their typical seasonal variation shows maximum values during spring and summer and minimum values during winter (Alvim-Ferraz et al., 2006). Several studies have concluded that the ozone concentrations are clearly higher at rural areas than at urban areas (Bayer-Oglesby et al., 2004; Dueñas et al., 2004).

In National Air Quality Monitoring Networks, ozone concentrations are measured with monitors working continuously. Data are collected via modem through specific software to calculate and store 15 minute averages. These measurements are costly and essentially designed for measuring at urban and suburban areas. The use of such equipment at remote areas is very difficult, reason why the values of ozone concentrations at remote areas are almost unknown (Manes et al., 2003; Sanz et al., 2007). Therefore, fpr monitoring at remote areas, alternatives were developed aiming to perform ozone measurements. A low-cost alternative and/or complement to continuous monitors is the use of passive samplers. These samplers require no power, are simple to assemble and operate and do not require calibration on the field (Bernard, et al., 1999; Krupa and Legge, 2000; Manes et al., 2003; Sanz et al., 2007).

The purposes of this work were to compare ozone concentrations at remote areas with urban ones influenced by traffic and to evaluate how nitrogen dioxide influences ozone concentrations in both, urban and remote areas.

2 Methodology

The study here reported was based on data measured at one urban site influenced by traffic in Oporto (PO) and at six remote sites: five at Bragança district (BG_1, BG_2, BG_3, BG_4 and BG_5) and one at Vila Real district, Lamas d'Olo (LO). PO site is located in a roundabout with several traffic streets, being considered an urban site mainly influenced by traffic. BG_1, BG_2, BG_3, BG_4, BG_5 and LO sites were located in natural environments not directly influenced by anthropogenic pollution sources and were, therefore, considered background remote sites.

Pollutant concentrations were measured with passive samplers (provided by Gradko International Ltd, England). To test their performance, the passive samplers were co-located with continuous monitors, at sites PO and LO. Those continuous monitors belong to the Air Quality Monitoring Network that is managed by *Comissão de Coordenação e Desenvolvimento Regional do Norte* (CCDR-N), under the responsibility of the Ministry of Environment. According to specified requirements, the sampling tubes were protected from sunlight and heat before and after exposure as well as during storage and transportation. Samplers were placed in an open field at a height of 2-2.5 m and were protected from rain and wind by appropriate shelters. Sampling tubes were simultaneously kept without exposure to be used as blanks for future analyses.

Pollutant concentrations were measured with passive samplers in two periods during the summer of 2006: 1st period - between 28/07/2006 and 10/08/2006 for PO and LO sites and between 27/07/2006 and 09/08/2006 for the other sites; and 2nd period - between 10/08/2006 and 05/09/2006 for PO and LO sites and between 09/08/2006 and 05/09/2006 for the other sites. The pollutants measured were ozone (O_3) and its precursors (recommended by the Directive 2002/3/EC): nitrogen dioxide (NO_2), total VOC and some specific VOC, namely, benzene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, m/p-xylene, o-xylene and toluene. O_3, NO_2, and VOC determination on diffusion tubes was performed, respectively, by ion chromatography, UV spectrophotometry and Gas Chromatography-Mass Spectrometry (GC-MS).

O_3 and NO_2 concentrations were also continuously monitored using, respectively, UV-

absorption photometry and chemiluminescence methods. The equipment for continuous monitoring was submitted to a rigid maintenance program being periodically calibrated.

3 Results and Discussion

3.1 Comparison between Passive and Continuous Monitoring

The accuracy of passive samplers was evaluated by comparing the O_3 and NO_2 data obtained using continuous monitors with those using passive samplers at sites PO and LO. Comparison of VOC concentrations was not possible since they were not continuously measured.

It was possible to observe that the differences between both measurements were very low. Table 1 shows the mean concentrations of O_3 and NO_2 measured using passive sampling and continuous monitoring and the respective modules of the absolute and relative differences calculated for both sites and periods.

Table 1. Mean concentrations of ozone and nitrogen dioxide measured with passive sampling and continuous monitoring and the respective modules of the absolute and relative differences calculated for both sites and periods.

Pollutant	Period	Site	Passive Sampling ($\mu g.m^{-3}$)	Continuous Monitoring ($\mu g.m^{-3}$)	Absolute Difference ($\mu g\ m^{-3}$)	Relative Difference (%)
O_3	1st	PO	51.04	54.00	2.96	5.5
		LO	87.09	89.52	2.43	2.7
	2nd	PO	40.90	44.83	3.93	8.8
		LO	113.21	109.11	4.10	3.8
NO_2	1st	PO	39.13	38.24	0.89	2.3
		LO	3.22	2.44	0.78	31.8
	2nd	PO	50.94	45.67	5.27	11.6
		LO	2.83	3.38	0.55	16.2

For O_3, the comparison of both methods showed a maximum absolute difference of 4.1 $\mu g.m^{-3}$ and relative differences lower than 8.8%. The maximum absolute difference for NO_2 was 5.3 $\mu g.m^{-3}$ and the relative differences were higher than 12% only for very low concentrations (2-3 $\mu g.m^{-3}$). These results indicated satisfactory reproducibility and precision of the measurements made using passive samplers.

3.2 Influence of Nitrogen Oxides and Volatile Organic Compounds on Ozone Concentrations

Figure 1 shows the O_3 concentrations measured at all sites, for both 1st and 2nd periods of passive sampling.

The lowest concentrations of O_3 were observed at the PO site being 51.0 $\mu g\ m^{-3}$ and 40.9 $\mu g\ m^{-3}$ for the 1st and 2nd periods, respectively. From all remote sites analysed, BG_4 was the one with the highest concentrations during both periods (97.9 $\mu g\ m^{-3}$ and 122.0 $\mu g\ m^{-3}$, respectively). As expected, during the period of passive sampling the exceedances of IT, AT, and TVPHH were greater at the LO site than at the PO site, being, approximately, 5, 8, and 2 times greater, respectively.

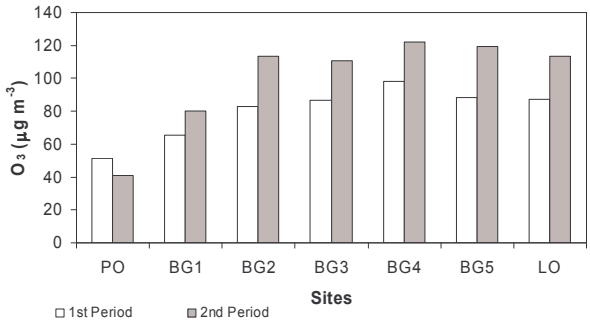

Figure 1. Ozone concentrations measured at all sites, during both 1st (around 305 h) and 2nd (around 640 h) periods of passive sampling.

It could be observed for PO site a typical profile of an urban area where O_3 formation was controlled by VOC concentrations, leading to a decrease on O_3 concentrations when NO_2 concentrations increased.

The NO_2 concentrations measured at all sites for both 1st and 2nd periods of passive sampling are presented in Figure 2.

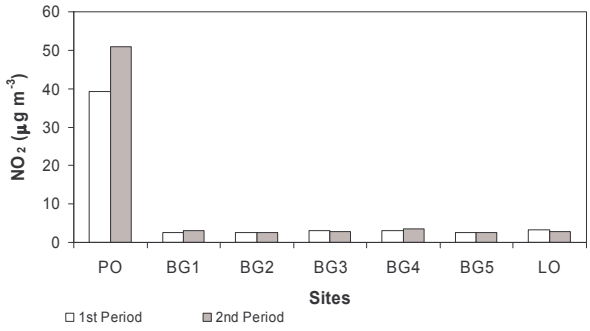

Figure 2. Concentrations of nitrogen dioxide measured at all sites during both 1st (around 305 h) and 2nd (around 640 h) periods of passive sampling.

NO_2 concentrations at PO site were, from 12 to 20 times higher than those at remote sites, due to the influence of traffic emissions. At remote sites, the concentrations were very low, being on average around 3 $\mu g\ m^{-3}$.

The total VOC concentrations during the periods of passive sampling are shown in Figure 3.

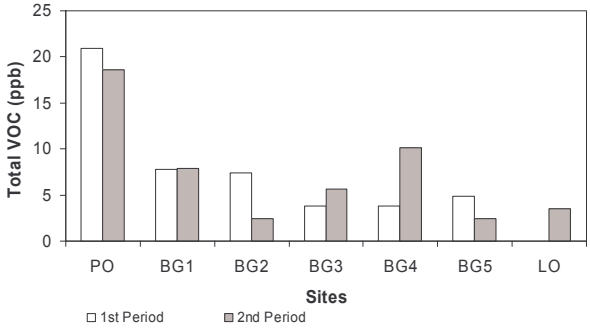

Figure 3. Concentrations of total volatile organic compounds measured at all sites during both 1st (around 305 h) and 2nd (around 640 h) periods of passive sampling.

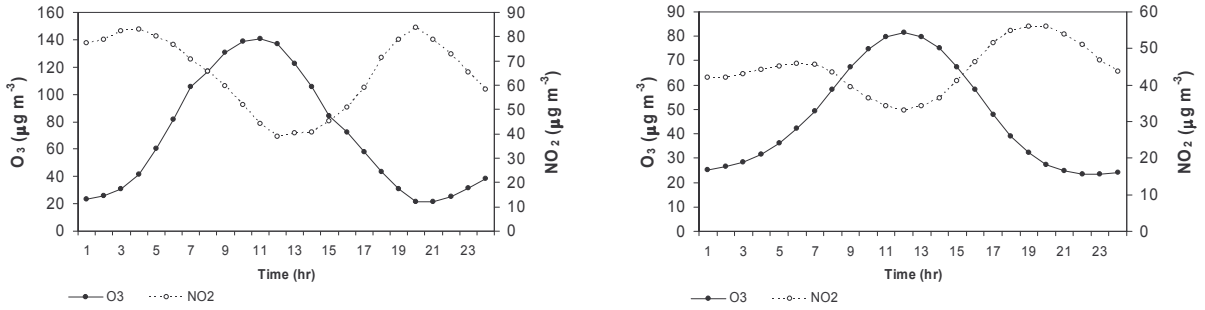
The VOC concentrations were also considerably high at PO site, being from 2 to 8 times higher than at remote sites, again confirming the traffic influence. The total VOC concentrations observed at remote sites were very low varying from 2.5 ppb to 10.1 ppb.

The concentrations of NO_2 and VOC were very low at remote sites, therefore confirming the absence of anthropogenic emission influence. However, it was simultaneously observed at these sites the highest concentrations of O_3 which can be explained through the competition between VOC and NO_2 for the OH radical. When [VOC]/[NO_2] is low, typical of urban areas, OH reacts predominantly with NO_2, retarding O_3 formation; thus, an increase of NO_2 concentrations leads to a decrease on O_3 concentrations. For higher [VOC]/[NO_2], typical of rural areas, OH reacts predominantly with VOC, accelerating O_3 formation: in this situation, an increase of NO_2 concentrations leads to an increase on O_3 concentrations (Seinfeld and Pandis, 1998).

Figure 4 shows a daily profile of 8-hour running averages at PO site for: (a) one day belonging to the period of passive sampling; and (b) the average values for all the period of passive sampling.

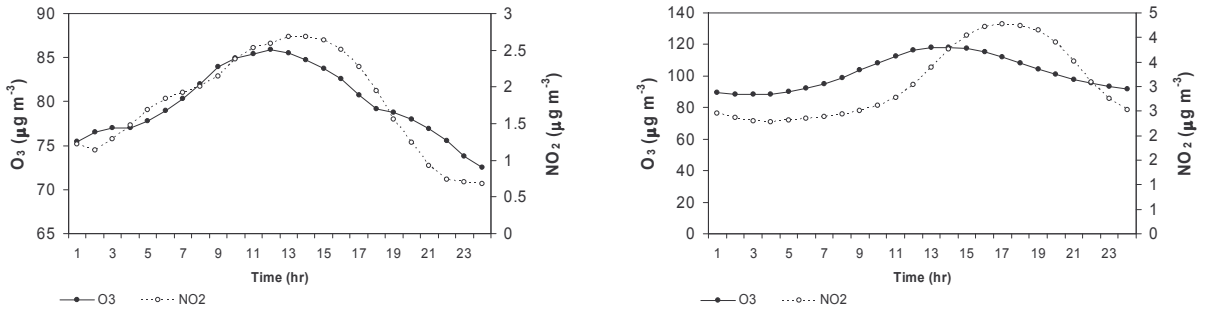


(a) (b)

Figure 4. Daily profile of 8-hour running averages at PO site for: (a) one day belonging to the period of passive sampling; and (b) the average for all the period of passive sampling.

For PO site, a typical profile of an urban area was observed where O_3 formation was controlled by VOC concentrations, leading to a decrease on O_3 concentrations when NO_2 concentrations increased.

Figure 5 shows a daily profile of 8-hour running averages at LO site for: (a) one day belonging to the period of passive sampling; and (b) the average values for all the period of passive sampling. For LO site, a typical profile of a rural area was observed where O_3 formation was controlled by NO_2 concentrations and therefore a decrease on O_3 concentrations led to a decrease in NO_2 concentrations.



(a) (b)

Figure 5. Daily profile of 8-hour running averages at LO site for: (a) one day belonging to the period of passive sampling; and (b) the average for all the period of passive sampling.

These results showed that [VOC]/[NO_2] were relatively high at LO site because of the relatively quicker removal of NO_x from distant sources compared to that of VOC, coupled with the absence of NO_x local sources. Concluding, the absence of anthropogenic sources at remote areas, led to very low concentrations of NO_2, that had determinant influence on the high concentrations of O_3.

4 Conclusions

At the urban site, ozone formation was controlled by volatile organic compound concentrations, leading to a decrease in ozone concentrations when nitrogen dioxide concentrations increased. At the remote sites, ozone formation was controlled by nitrogen dioxide concentrations, due to its very low level. Accordingly, a decrease on ozone concentrations was observed when nitrogen dioxide concentrations decreased.

Keywords: PM_{10}, $PM_{2.5}$, PIXE, tobacco smoke, carcinogenic elements
Topic: Suitable process-product development trough green chemistry—Environmental engineering & management.

Abstract

Tobacco smoking is one of the greatest sources of the indoor inhalable (PM_{10}) particles. In past, the studies conducted on indoor particulates were mostly related to PM_{10}, however in the last decade respirable particles ($PM_{2.5}$) and even smaller particles (PM_1) began to be more important as they penetrate deeper in the respiratory system, causing severe health effects. Therefore, more information on fine particles should be provided. Aiming a further evaluation of the tobacco smoke impact on public health, this work evaluates the influence of tobacco smoke on the characteristics of PM_{10}, $PM_{2.5}$, and PM_1 considering concentration and elemental composition. Samples were collected at sites influenced by tobacco smoke, as well as at reference sites, using low-volume samplers; the element analyses were performed by Proton Induced X-ray Emission (PIXE).

It was found that tobacco smoke increased the total concentrations of five carcinogenic elements (Cr, Ni, As, Cd and Pb) 1100-2400% for PM_{10} and 840-2200% for $PM_{2.5}$. The analysis of elemental ratios confirmed that tobacco smoking mainly influenced the composition of the fine fraction of particles; as these smaller particles have a strong influence on health, these conclusions are relevant for the development of strategies to protect public health.

1 Introduction

Tobacco smoking (TS), a world wide habit, is certainly one of the greatest sources of the indoor inhalable particles, not only for the smokers but also for all those who are somehow exposed to it. Voluminous literature and public media linked the active tobacco smoking to lung and heart diseases and to cancers of various organ systems. However, passive smoking, i.e., exposure to secondhand tobacco smoke, also called environmental tobacco smoke (ETS), has also became an important health issue. It increases the risk and frequency of respiratory symptoms (wheeze, cough, breathlessness and phlegm) (WHO, 1999), being a proven cause of respiratory diseases of the lower airways (croup, bronchitis, bronchiolitis, pneumonia) in childhood and probably also during adulthood (Skorge et al., 2005). In 1993, the US Environmental Protection Agency (US EPA) classified ETS as a ‘‘Class 1’’ human carcinogen (EPA, 1993); accordingly, the International Agency for Research on Cancer unanimously stated that ETS is carcinogenic to humans (IARC, 2002). Over 4000 different chemicals have been identified in tobacco smoke that is a complex mixture of gaseous components including carbon monoxide, benzene, formaldehyde, toluene, and of particles of different sizes (Paoletti et al., 2006) mainly constituted by carbonaceous compounds, aromatic hydrocarbons with high molecular number, nicotine, and heavy metals; as most of particle components have known impacts on health, the exposure to particles represents serious risk to human health.

In the past years, many epidemiological studies (Alvim-Ferraz et al., 2005) showed a strong association between the exposure to PM_{10} (particles with aerodynamic diameter smaller than 10 μm) and especially to $PM_{2.5}$ (particles with aerodynamic diameter smaller than 2.5 μm) and the increase of morbidity and mortality rates, caused by pulmonary and cardiovascular diseases. The size of particles is an important characteristic because it determines the place of particle deposition in the respiratory systems, the smaller the particles, the deeper the penetration. While coarse particles deposit mainly in the nose and throat, fine particles can penetrate in the deeper parts of the lungs and they are able to reach the alveoli. Therefore, recent attention has been focused on $PM_{2.5}$ and PM_1 (particles with aerodynamic diameter smaller than 1 μm). It is still not clear though, whether the particles mass concentration itself accounts for the majority of the adverse health effects, as it is commonly belief that chemical composition may also significantly contribute to health effects of PM.

Despite several studies conducted on tobacco smoking, there is still information missing, mainly related to detailed physical-chemical characteristics of tobacco smoke particles. To further understand the impact of tobacco related particulate matter on public health, this study evaluated the influence of tobacco smoke on the characteristics of PM_{10}, $PM_{2.5}$ and PM_1, considering concentration and elemental composition of five carcinogenic elements (Cr, Ni, As, Cd and Pb).

2 Methods

The monitoring of PM_{10}, $PM_{2.5}$ and PM_1 was conducted during summer-autumn 2006 at four sites situated in Paranhos district of Oporto city in Portugal: two directly influenced by tobacco smoke, one office (Ts_1) and one cafeteria (Ts_2), and two homes not directly influenced by tobacco smoke, reference sites Rf_1 and Rf_2. At each site the sampling was conducted for 28 consecutive days. The number of occupants during sampling as well as other characteristics, such as the presence and use of electronic and cooking devices, cleaning activities and room ventilation were observed. Mechanical ventilation did not exist at the motoring sites; natural ventilation was provided by opening windows as occupants thought necessary.

Samples of indoor PM were daily collected for 12-h in order not to over-load filters for consequent chemical analysis. Sampling was done using TCR TECORA Bravo H2 constant flow samplers, combined with PM EN LVS sampling heads in compliance with the norm EN12341, using an air flow rate of 38.3 L min^{-1}. Inlets were placed 1.5 m above the floor and about 1 m from the walls, without obstructing the normal usage of the rooms. In order to perform different chemical analysis, two types of filter media were used; in alternating days PM_{10} and $PM_{2.5}$ were collected on polytetrafluoroethylene (PTFE) membrane filters with polymethylpentene support ring (2 μm porosity, Pall Life Science Teflon™), or on quartz fiber filters (∅47mm Schleicher & Schuell). PM_1 were collected on quartz fibre filters only as the respective sampler did not allow different filters.

PM masses were determined gravimetrically by subtracting the initial average mass of the blank filter from the final average mass of the sampled filter; the difference was then divided by the total volume of air that passed through filter (at 25°C and 101.3 kPa).

The elemental compositions of PM_{10} and $PM_{2.5}$ were determined by Proton Induced X-ray Emission (PIXE), which provided analysis for elements from magnesium trough uranium. For elemental analysis the PTFE filters were cut in half. One half was analysed while the other part was kept for possible replicates and other analysis. The analyses were performed at the ITN van de Graaff accelerator. As PM_1 were collected on quartz fibre filters it was not possible to determine the respective elemental composition.

For the data treatment, the Student's t-test was applied to determine the statistical significance ($P<0.05$, two tailed) of the differences between the determined means.

3 Results and discussions

At sites influenced by tobacco smoke, PM_{10} concentrations ranged from 21.3 to 220 μg m^{-3} (mean of 107 μg m^{-3}) and from 111 to 242 μg m^{-3} (mean of 156 μg m^{-3}), the corresponding $PM_{2.5}$ concentrations ranged from 17.6 to 202 μg m^{-3} (mean of 103 μg m^{-3}) and from 95.0 to 213 μg m^{-3} (mean of 132 μg m^{-3}). The reference sites exhibited lower values of PM, ranging from 8.4 to 58.8 μg m^{-3} (mean of 29.3 μg m^{-3}) and 6.8 to 44.8 μg m^{-3} (mean of 23.6 μg m^{-3}) for PM_{10} concentrations; the corresponding $PM_{2.5}$ concentrations ranged from 6.9 to 58.2 μg m^{-3} (mean of 24.6 μg m^{-3}) and from 6.1 to 40.5 μg m^{-3} (mean of 16.9 μg m^{-3}). PM_1 concentrations ranged from 17.1 to 153 μg m^{-3} (mean of 84.2 μg m^{-3}) and from 69.3 to 181 μg m^{-3} (mean of 110 μg m^{-3}) at the sites influenced by tobacco smoke; at the references sites PM_1 ranges were 5.5 to 44.7 μg m^{-3} (mean of 17.3 μg m^{-3}) and 3.6 to 30.2 μg m^{-3} (mean of 13.4 μg m^{-3}). In general, the results showed that tobacco smoke increased concentrations 270-560% for PM_{10}, 320-680% for $PM_{2.5}$ and 390-720% for PM_1. The statistical analysis of these results indicated that: i) as expected, PM_{10}, $PM_{2.5}$ and PM_1 concentrations were significantly higher at the sites influenced by tobacco smoking than at the reference ones; ii) the differences observed between PM_{10} means at sites Ts_1 and Ts_2 were statistically significant; iii) the differences observed between $PM_{2.5}$ means (as well as between PM_1) at sites Ts_1 and Ts_2 were not statistically significant; iv) the differences observed between PM_{10} means at sites Rf_1 and Rf_2 were statistically significant; v) the differences observed between $PM_{2.5}$ means (as well as between PM1) at sites Rf_1 and Rf_2 were not statistically significant; vi) PM_{10} and $PM_{2.5}$ means were significantly different at sites Ts_2 and Rf_2 but not at sites Ts_1 and Rf_1. In general, the results showed that tobacco smoke increased concentrations 270-560% for PM_{10}, 320-680% for $PM_{2.5}$ and 390-720% for PM_1. These results allowed concluding that tobacco smoke strongly increased PM concentrations, this increase being clearly higher for smaller particles.

To further understand the influence of tobacco smoke on public health, the elemental composition of PM was analysed with more detail. The elements listed as human or animal carcinogens are chromium (Cr), nickel (Ni), arsenic (As), cadmium (Cd) and lead (Pb), beryllium (Be), cobalt (Co) and mercury (Hg) (ATSDR, 2003). Of these Cr, Ni, As, Cd and Pb were reported to be the carcinogenic elements in ETS (Smith et al., 1997). In total, 25 elements were determined using the PIXE technique to characterize PM_{10} and $PM_{2.5}$ sampled at the two sites influenced by tobacco smoke and at the two reference sites, of these five elements were the carcinogenic ones: Cr, Ni, As, Cd and Pb. The mean concentrations of these carcinogenic elements (ng m^{-3}) in PM_{10} and $PM_{2.5}$ are presented in Figure 1.

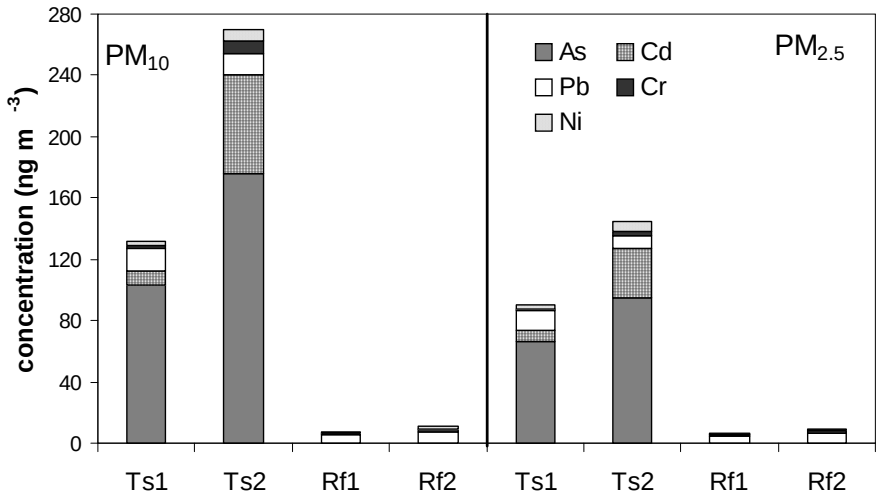

Figure 1. Comparison of mean concentrations of carcinogenic elements at two sites influenced by tobacco smoke (Ts1, Ts2) and two reference sites (Rf1, Rf2).

The obtained results showed that: i) at both sites influenced by tobacco smoke the levels of Cr, Ni, As, Cd and Pb in both fractions were significantly higher than at the reference sites; ii) the highest levels of Cr, Mn, Ni, As, Cd and Pb in both fractions were recorded at site Ts_2. From this figure it is also clear that at sites influenced by tobacco smoke, As was the most abundant element in both PM (ranging from 103 to 176 $\mu g\ m^{-3}$ and from 66 to 95 $\mu g\ m^{-3}$ in PM_{10} and $PM_{2.5}$, respectively). As and Cd occurred only in PM of sites with tobacco smoking, showing its strong influence on the presence of carcinogenic elements in indoor air. Pb concentrations at these sites were 110-180% and 30-190% higher than at the reference sites for PM_{10} and $PM_{2.5}$, respectively. Cr and Ni exhibited lower concentrations than As, Cd and Pb, mainly for the reference sites. Still, at the sites influenced by tobacco smoke, Cr and Ni concentrations in PM_{10} were 15-680% and 15-480% higher, respectively; the concentrations in $PM_{2.5}$ were 20-250% and 10-490% higher for Cr and Ni, respectively. The obtained results showed that by tobacco smoke increased 1100-2400% and 840-2200% the total concentrations of five carcinogenic elements (Cr, Ni, As, Cd and Pb) in PM_{10} and $PM_{2.5}$, respectively.

To understand better the distribution of elements between both PM fractions, the elemental concentrations of particles with sizes between 2.5 and 10 μm were calculated ($PM_{2.5-10}$). Figure 2 presents the mean ratios of elemental concentrations (expressed in $\mu g\ g^{-1}$) in $PM_{2.5}$ versus $PM_{2.5-10}$ for the sites influenced by tobacco smoking.

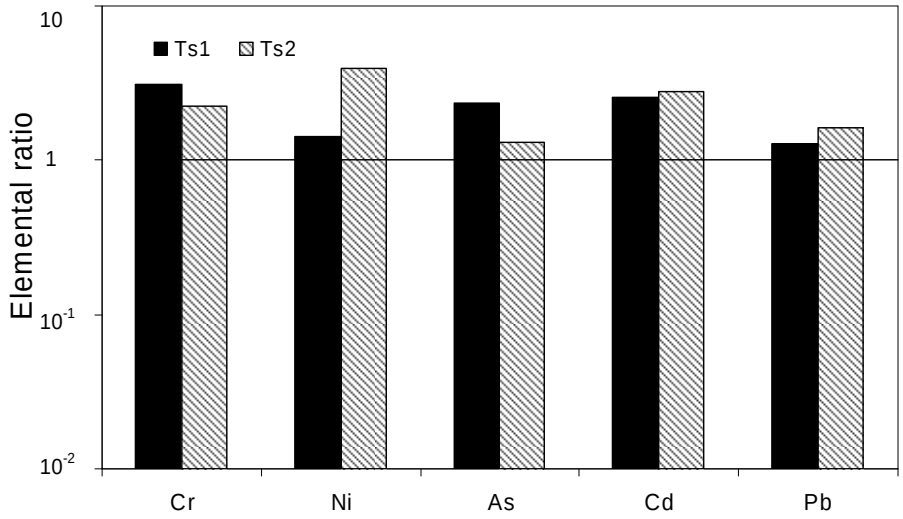

Figure 2. Mean ratios of elemental concentrations ($\mu g\ g^{-1}$) in $PM_{2.5}$ versus $PM_{2.5-10}$ at sites influenced by tobacco smoke.

At both sites influenced by tobacco smoking Cr, Ni, As, Cd and Pb exhibited ratios higher than 1 being the highest for Cr and Ni at Ts_1 and Ts_2, respectively. Thus, $PM_{2.5}$ was clearly the most important fraction for these five carcinogenic elements. Justifying the observed values, tobacco smoking was responsible for emissions of Cr, Ni, As, Cd, Pb present the mostly in the fine fraction.

The mean ratios of the elemental composition in $PM_{2.5}$ versus $PM_{2.5-10}$ at the references sites (Figure 3) showed that the behaviour of the background sites were different from those of the sites influenced by tobacco smoking. At both references sites only Ni exhibited the ratios higher than 1 showing that it was predominantly present in $PM_{2.5}$. For the other elements $PM_{2.5-10}$ was the prevailing fraction.

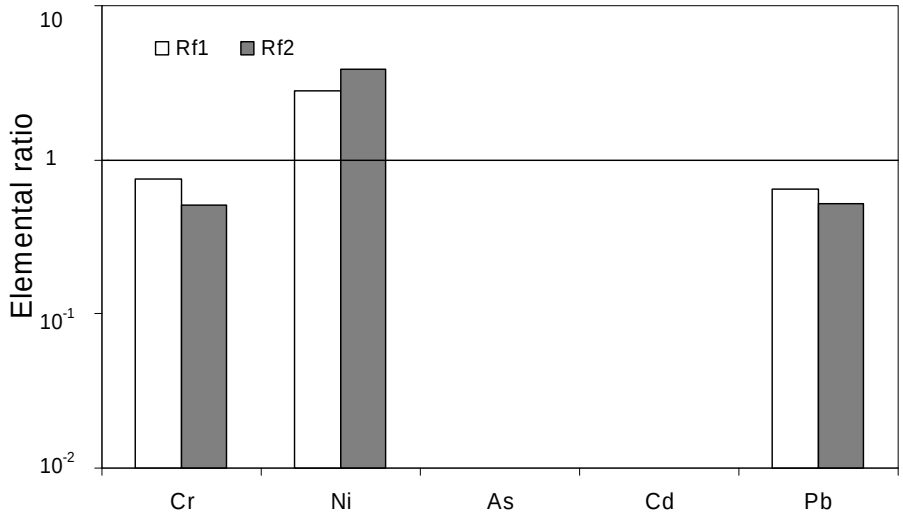

Figure 3. Mean ratios of elemental concentrations ($\mu g\ g^{-1}$) in $PM_{2.5}$ versus $PM_{2.5-10}$ at the reference sites.

4 Conclusions

Tobacco smoke strongly increased PM concentrations, this increase being clearly higher for smaller particles: 270-560% for PM_{10}, 320-680% for PM2.5 and 390-720% for PM_1. Levels of Cr Ni, As, Cd and Pb in PM_{10} and $PM_{2.5}$ reached values higher when influenced by tobacco smoke. Namely, for these five carcinogenic elements the total increase was 1100-2400% and 840-2200% for PM_{10} and $PM_{2.5}$, respectively. Cr concentrations were 15-680% and 20-250% higher in PM_{10} and $PM_{2.5}$, respectively. Ni concentrations were 15-480% and 10-490% higher in PM_{10} and $PM_{2.5}$, respectively. As and Cd occurred only in PM of sites with tobacco smoking. Pb concentrations were 110-180% and 30-190% higher than at the reference sites for PM_{10} and $PM_{2.5}$, respectively. These carcinogenic elements were predominantly present in the fine fraction. Thus, tobacco smoking mainly influenced the composition of the fine fraction of particles; as these smaller particles have a strong influence on health, these conclusions are relevant for the development of strategies to protect public health.

Keywords: Polymer recycling, Polymer separation, Polymer analysis, Selective Dissolution, Fourier Infrared Spectroscopy
Topic: Sustainable process-product development through green chemistry.

Abstract

The work reported herein is part of a larger project aiming at developing a technology for the mechanical separation of plastics waste from drop-off-points. It uses analytical methods to characterize ternary mixtures of polymers that are difficult to separate by gravity techniques. Model mixtures of recycled PET/PVC/PS were separated using a method developed by G. Pappa et al (2001) and Nauman (1994) and were analyzed using solubility tests, thermogravimetry and infrared spectroscopy. Two approaches to this method were studied, one using the selective dissolution with flash evaporation (SD/FE) of the solvent and the other using selective dissolution with reprecipitation (SD/R) of the dissolved polymer. The solubility tests showed that the plastics in the ternary mixture could be separated in two steps. First, PS could be separated by dissolution in toluene, which does not dissolve PVC and PET at room temperature, and second, PVC could be separated from the remaining binary mixture using tetrahydrofuran as it does not dissolve PET at room temperature, remaining as the non dissolved plastic. TGA proved to be a very useful technique to assess PVC contamination, allowing the detection and quantification of small amounts of PVC in mixtures with other polymers. Infrared spectroscopy was used as a tool to detect the presence of polymers in mixtures, when they presented distinct characteristic IR bands. These analytical methods were used to determine the composition of plastic waste mixtures obtained through physical separation techniques developed in this project.

1 Introduction

Due to the increase of waste production in the last decades, the recycling of plastics and other materials is no longer seen as an option but as an obligation of the concerned society we are living in. It is the government's responsibility not only to develop the legislation for waste management and recycling activities, but also to support research and technologies in this area.

The plastics found in Municipal Solid Waste (MSW), originated mainly from packaging, became a serious environmental problem and a source of pollution because of their short life time and fast discard. The recycling of these plastics is a difficult problem to solve due to the level of contamination and the presence of a large variety of plastics. The recycling of heterogeneous mixed plastics must be preceded by their separation, due to the physico-

* Corresponding author. Tel + 351-253-510065. E-mail: liliana.rosa@piep.pt

chemical incompatibility of the different plastics and thus the difficulty in obtaining recycled materials with good mechanical properties directly from their mixtures.

There are two main types of plastics separation. The first is based on the separation by one physico-chemical property (Agante et al, 2004, Falconer, 2003, Dodbiba and Fujita, 2004), such as a difference in density, tribological separation, or use of infrared spectroscopy, and the second is the separation based on differences in solubility. The processes based on solubility are an alternative path for secondary recycling by type of plastic, and implicates the dissolution of the waste plastic with solvents and their subsequent recovery (Poulakis and Papaspyrides, 1995, 1997 and 2001).

The separation processes based on solubility include dissolution of a number of incompatible polymers in a common solvent, at different temperatures, or in different solvents, separating each polymer at a time. The polymer can be recovered either by fast evaporation of the solvent, using selective dissolution, or by the addition of an appropriate non-solvent (NS), that precipitates the polymer. The application of these methods to the separation of plastic waste, however, cannot be used because it would cause environmental problems due to the use of large amounts of solvents (Pappa et al, 2001).

The work reported here is part of a project under development in Portugal for the implementation of a pilot plant for the mechanical separation of granulated plastics from packaging waste. The project SEMEC, financed by Sociedade Ponto Verde (SPV), aims at the development of a low-cost, environmentally friendly methodology for the separation of the different plastics occurring at drop-off-points. The partners of the project are CERENA (a research center of Instituto Superior Técnico), PIEP (a research center at Minho University), Tratolixo (a solid waste management company, responsible for the collection of solid wastes in an area nearby Lisbon), and Selenis-Ambiente (a Portuguese PET recycling company). The partners from CERENA are involved in the development of separation technologies, while the PIEP/DEP partners are involved in the development of analytical methods for the characterization of the composition of the separated plastics.

The analysis of the plastic mixtures from MSW before and after separation was based on a selective dissolution method (Nauman and Lynch, 1994). The method used for selective dissolution tests in model mixtures of recycled plastics involved the following steps: (a) addition of a solvent to selectively dissolve only one of the polymers, under certain conditions; (b) filtration to remove the non dissolved polymers; (c) solvent evaporation to recover the dissolved polymer and for reuse of the distilled solvent (in the SD/FE method) or addition of a non-solvent (NS) to precipitate the dissolved polymer (in the SD/R method); (d) application of the same procedure for each polymer in the mixture.

In practice, for the mixtures from MSW the plastics were washed and the polyolefin fraction separated by density difference, in a water tank. The remaining plastics were constituted mostly by polystyrene (PS), polyvinyl chloride (PVC) and polyethylene terephthalate (PET). These were the plastics used in the dissolution process for mixtures quantification.

This analytical method allowed the systematic characterization of the fractions of MSW plastics separated by different mechanized methods, and to assess the interest and possible applications of the separated plastics according to the degree of purity or type of contaminations measured.

2 Experimental

Materials and Solvents

The materials used in the model mixtures of PET, PVC and PS were sent by *CERENA* and the plastics from Municipal Solid Waste (MSW), were collected by *Tratolixo.*

The solvents used were general reagent grade chemicals; toluene 28701, tetrahydrofuran Rectapur 28552 and methanol 20903, from VWR BDH Prolabo.

Polymer Recovery by the Selective Dissolution Process

The selective dissolution process consists in dissolving one polymer, in a mixture of polymers, using a solvent that dissolves that polymer at room temperature but doesn't dissolve the others. The recovery of the dissolved polymer can be made either by fast evaporation of the solvent or by the addition of a non-solvent (NS) that precipitates the polymer.

In order to test the selective dissolution/fast evaporation process (SD/FE), the ternary mixtures of plastics (PET/PS/PVC), in the form of granules, were weighed and stirred in toluene, at room temperature, with a magnetic stirrer. At room temperature, toluene dissolves PS but not PET or PVC. The PS solution was transferred to a flask, the solvent was evaporated and the PS was recovered. The procedure was repeated for the remaining PET/PVC binary mixture using tetrahydrofuran (THF) as a solvent. THF dissolves PVC at room temperature but not PET. The PVC solution was evaporated and the remaining PVC was recovered. PET was obtained as the remaining solid fraction.

For selective dissolution/reprecipitation (SD/R) the process was similar from the described above, but instead of evaporating the solvent, a non-solvent (methanol) was added to precipitate the dissolved polymers (PS in toluene and PVC in THF).

The separated plastics were then dried in a vacuum oven during 6 hours at 120 ºC for PS and PVC and at 160 ºC for PET. After drying, all the samples were identified by infrared spectroscopy (FTIR) and some of them were characterized by thermogravimetry (TGA).

The described methods were applied to ternary model mixtures of polymers, to evaluate the separation efficiency of the techniques, in order to be used later for the quantification of polymers in mixtures sampled from MSW, studied in the aim of the project SEMEC.

Fourier Transform Infrared Spectroscopy (FTIR)

The identification of the separated plastics was carried out on a FTIR Perkin Elmer 1610 instrument. Thin films of the samples were prepared in a hot press at 200 ºC for PS and PVC and at 290 ºC for PET and the FTIR spectra was acquired between 4400 and 450 cm^{-1}.

Thermogravimetry (TGA)

A thermogravimetric balance TA Instruments Q500 was used for the quantification of PVC in binary and ternary mixtures. Sample weights were approximately 10 mg, and the heating rate was 10 ºC/min from 100 ºC to 600 ºC, under nitrogen atmosphere.

3 Results and Discussion

Polymer Recovery by the Selective Dissolution Process

Model ternary mixtures of PET/PS/PVC were used to test the selective dissolution process and establish the best conditions for the laboratory procedure. The polymers separated by this process were dried, weighed, and identified by FTIR. The composition of the polymer mixtures before recovery and the weight % of the individual polymers recovered after solvent selective dissolution is presented in Table 1.

It was observed that, for the SD/FE process, the amount of material recovered by dissolution in toluene was higher than the amount of PS incorporated in the model mixture. This was mostly due to the solubility of the plasticizers contained in PVC that were partially dissolved in toluene. This was confirmed by FTIR of the residue obtained after solvent evaporation of PVC/toluene suspensions prepared in similar conditions as for PS dissolution. Other types of additives may also dissolve in toluene, but they were present in trace amounts.

Table 1 Weight percent composition of the polymer mixtures before separation and after recovery by selective dissolution/fast evaporation (SD/FE) and by selective dissolution/reprecipitation (SD/R).

Sample	PS (%)		PVC (%)		PET (%)		Total weight % of plastic recovered
	Before	***After***	***Before***	***After***	***Before***	***After***	
SD/FE	5.04	5.39	10.03	9.63	84.93	83.74	98.75
Stand. Dev.	0.04	0.11	0.02	0.12	0.05	0.48	0.47
SD/R	5.02	4.51	10.05	8.91	84.94	84.55	97.97
Stand. Dev.	0.03	0.21	0.02	0.29	0.04	0.06	0.34

In order to evaluate the typical amount of additives dissolved in toluene and THF, suspensions of PVC and of PET in toluene, and of PET in THF, were prepared in similar conditions as those used for the dissolution of PS and PVC. For the samples studied it was observed that toluene dissolved 3.54±0.12% of the initial weight of PVC, and 0.04±0.00% of the PET, and that THF dissolved 0.12±0.01% of the initial weight of PET. The solubility of PET additives in toluene is very low, and also relatively low in THF. PVC presents much higher weight loss due to the high amount of plasticizers usually incorporated in this polymer. This amount will vary from batch to batch, depending on the composition of the PVC waste present in the MSW.

The results obtained by reprecipitation of the polymer (SD/R) showed slightly higher losses in the polymer recovery but provided a more accurate estimate for the polymer mixture composition, since it was free from the interference of the soluble additives.

A typical sample from MSW was obtained from Tratolixo. At CERENA the sample was washed, the polyolefins separated from the other plastics by density difference, in water, and the remaining plastics mixture was analyzed at PIEP using the SD/FE method. The composition obtained for the MSW sample is presented in Table 2.

Table 2 Weight percent composition of the polymer mixtures obtained from MSW, determined by selective dissolution/fast evaporation (SD/FE)

Sample	Initial weight (g)	PS (%)	PVC (%)	PET (%)	Total weight % of plastic recovered
SD/FE	4.87	2.31	5.14	92.30	99.75
Stand. Dev.	0.29	0.78	1.03	1.58	0.16

Fourier Transform Infrared Spectroscopy (FTIR)

The different polymer fractions separated by selective dissolution were analyzed by FTIR. The spectra obtained identified the presence of pure PS, PET and plasticized PVC, indicating an efficient separation of the mixed polymers by selective dissolution, as shown in Fig. 1. For the PVC, the esther bands observed in the FTIR spectra are due to the presence of plasticizers, usually phtalates. Most of the plasticizers can be removed by Sohxlet extraction with ether (Fig. 1).

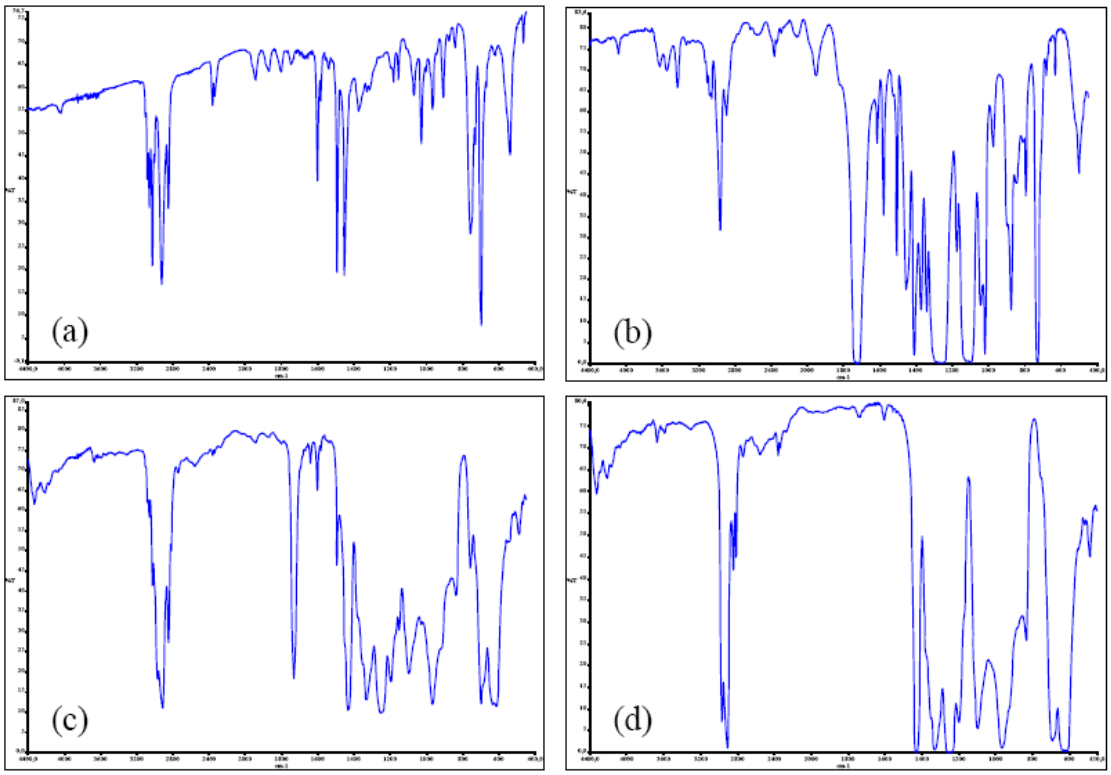

Figure 1 Infrared spectra of recovered samples: (a) PS, (b) PET, (c) PVC with plasticizer and (d) PVC without plasticizer.

Thermogravimetry (TGA)

The thermal degradation of PET and PS, in nitrogen, follows a very similar path, presenting one degradation step above 400ºC. The thermal degradation of PVC is different from the other polymers, presenting two degradation steps. The first step appears at a relatively low temperature (above 270ºC), corresponding to the elimination of HCl, and the second at a higher temperature, corresponding to the degradation of the carbonaceous backbone. This first dehydroclorination step of PVC is a characteristic step that can be used to quantify the amount of PVC present in polymer mixtures, at a concentration level not lower than approximately 1%. Thus, the weight loss observed in the first degradation step, above 270ºC, will correspond to approximately 58.3% of the PVC present in the sample. Figure 2 represents the TGA curve obtained for pure PVC (a) and for a mixture of polymers containing approximately 5% in weight of PVC (b).

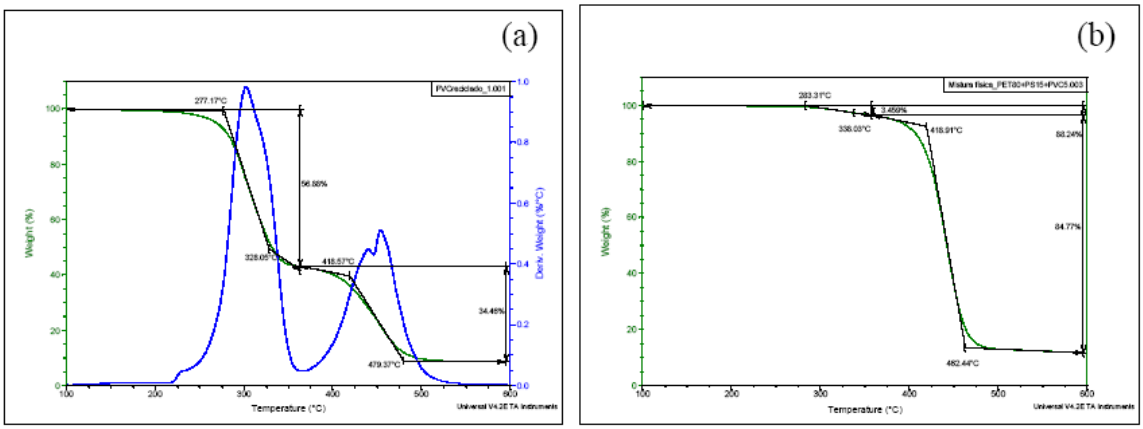

Figure 2 Thermograms of samples containing: (a) 100% of PVC; (b) 80% of PET, 15% of PS and 5% of PVC, obtained by heating at 10 ºC/min under N_2.

4 Conclusions

The conditions used in the selective dissolution/fast evaporation (SD/FE) and in the selective dissolution/reprecipitation (SD/R) methods described were efficient in the separation of plastics in model mixtures. The separated plastics were recovered with higher yield in the SD/FE method and with higher purity in the SD/R method. For fast and low cost quantification of the plastics present in the mixtures the SD/FE method was preferred, although there may be contamination from additives of the other plastics in the solution. The SD/R method was better suited for the separation of pure plastics, or when there is an interest in reusing the recovered plastics, but this method revealed to be more expensive and time consuming.

Small amounts of PVC in plastic mixtures could be quantified by TGA, for PVC contents higher than approximately 1 %.

The SD/FE method was used with success for the characterization of the MSW sample.

Topic: Sustainable process-product development through green chemistry.

Abstract

In this work, non-woven geotextiles, made from polypropylene fibres stabilised with different amounts of the additive Chimassorb 944 (0%, 0.2% and 0.4%), were exposed to ultraviolet radiation (different radiant exposures) in a laboratory weatherometer. The photo-degradation suffered by the geotextiles was studied by infrared spectroscopy and by scanning electron microscopy. Simultaneously, the level of Chimassorb 944 on the geotextiles was monitored by liquid chromatography with spectrophotometric detection.

1 Introduction

Geotextiles (GTXs) are polymeric materials widely applied in the construction of infrastructures (such as, landfills, roads, railways, tunnels, dams and reservoirs) due to economical, technical and environmental advantages. In those applications, the GTXs can be exposed to several degradation agents (ultraviolet radiation and other weathering agents, atmospheric oxygen, high temperatures, chemicals and microorganisms), that may decrease their durability.

Among all the degradation agents, exposure to sunlight is considered one of the most damaging for the GTXs. The solar radiation that reaches the earth surface has wavelengths between 295 nm and 3000 nm. However, only the ultraviolet (UV) radiation (between 295 nm and 400 nm) is sufficiently energetic to initiate the polymeric degradation of the polymers used on the production of GTXs (polypropylene and polyester are the most used ones). The high-energetic UV radiation can promote the formation of high-reactive free radicals and, in the presence of oxygen, it is possible the occurrence of photo-degradation of the polymeric chains of the GTXs, according to the following reaction (Suits and Hsuan, 2003):

$$RH + O_2 + h\nu \rightarrow R\bullet + ROO\bullet + RO\bullet + \bullet OH$$

where RH is the polymer chain, *hv* is the energy supplied by UV radiation and R•, ROO•, RO• and •OH are free radicals formed during the degradation process. Hydroperoxides are successively formed and then decomposed during the photo-degradation of polyolefins (Commereuc *et al.*, 1997). The presence of carbonyl groups (resultant from the decomposition of hydroperoxides) in a degraded polymer indicates that oxidation has occurred (Kaci *et al.*, 2000). The degradation mechanism induced by UV radiation will continue until all free radicals are transformed into non-reactive species (for example, by the action of an antioxidant). This degradation process is usually accelerated by high temperatures and by the existence of high moisture contents on the materials.

* Corresponding author. Tel + 351225081613. E-mail:rcarneir@fe.up.pt

The simplest way to protect the GTXs against photo-degradation is by avoiding exposing them to sunlight. However, the elimination of all exposition to sunlight is in the majority of the cases impossible and, in some situations, the GTXs can be exposed during long periods of time (months or even years). In order to retard and/or inhibit the photo-degradation process, chemical stabilisers (such as UV stabilisers, antioxidants and pigments) are often added to the GTXs composition.

Nowadays, many techniques are available for evaluating the photo-degradation suffered by polymeric materials. For instance, chemical changes arising from exposing materials to UV radiation can be investigated by infrared spectroscopy, while changes on the materials surface can be characterised by microscopic techniques; mechanical tests are available for determining changes on the mechanical properties of the materials. Several analytical methods are also described in literature for the determination of many chemical additives often present in polymeric materials.

2 Experimental description

In this work, we studied three non-woven GTXs (mass per unit area of 500 $g.m^{-2}$) made from polypropylene (PP) fibres stabilised with different amounts (0%, 0.2% and 0.4%, *w/w*) of the additive Chimassorb 944 (C944). C944 is an additive widely used in the stabilisation of polyolefins against the damaging effects of oxygen and UV radiation.

The GTXs were exposed to UV radiation, at the temperature of 60 ºC, in a laboratory weatherometer – the QUV (Q-Panel Lab Products, model QUV/spray). Fluorescent UV lamps (type UVA-340) were used as the UV radiation source (these lamps provide a very good simulation of the UV radiation emitted by sunlight). The GTXs were exposed to different total UV (290-400 nm) radiant exposures of 35 $MJ.m^{-2}$, 69 $MJ.m^{-2}$, 104 $MJ.m^{-2}$ and 138 $MJ.m^{-2}$.

The degradation suffered by the PP fibres was studied by Fourier transform infrared spectroscopy (FTIR) and by scanning electron microscopy (SEM). The infrared analyses were performed in a spectrometer from Perkin-Elmer (model Spectrum RXI FT-IR system). PP fibres (mass of about 5 mg) were grinded and then crushed in a mechanical press to form translucent pellets. SEM analysis was used to characterise the microscopic changes occurred on the PP fibres during the exposition to UV radiation.

A simple methodology was developed for the determination of C944 on the PP fibres. This methodology can be divided in two main steps: (1) ultrasonic extraction with chloroform at 60 ºC for removing C944 from the samples; (2) separation and determination of the additive by liquid chromatography with detection at 244 nm. The ultrasonic extractions were performed in an ultrasonic bath from Bandelin Sonorex (model TK52, frequency of 35 kHz). For the chromatographic analyses, a Jasco HPLC equipment was used, consisting of a flow pump Jasco (model PU-2089 Plus), a Rheodyne (model 7725(i)) injection valve with a 20 μL loop, a spectrophotometric detector Jasco (model UV-2070 Plus) and an interface box Jasco LC-Net II/ADC. A pre-column Kromasil NH_2 (10 mm x 4 mm, 5 μm particle size) and a column Kromasil NH_2 (250 mm x 4.6 mm, 5 μm particle size) from Hichrom were used. Isocratic elution was used with a flow of 1 $mL.min^{-1}$ of chloroform. In these conditions, C944 had a retention time of about 5 minutes.

3 Main results

The UV-exposure tests caused serious damages on the GTX without the additive C944. Indeed, just after an exposure of 35 $MJ.m^{-2}$ of UV radiation, this GTX was reduced into small pieces or powder (the unstabilised PP fibres depolymerised completely). The exposition to higher amounts of UV radiation (69, 104 and 138 $MJ.m^{-2}$) resulted in similar damages for this material.

The GTXs stabilised with 0.2% and 0.4% of C944 were not completely destructed after the exposition to 35 $MJ.m^{-2}$ of UV radiation, which showed the importance of C944 on the protection of the materials against photo-degradation. However, after the exposition to 104 $MJ.m^{-2}$ of UV radiation, both GTXs were releasing small pieces of depolymerised fibres (almost powder), which indicated the existence of serious damages on their polymeric structure. After exposition to 138 $MJ.m^{-2}$ of UV radiation, the GTX with 0.2% of C944 was near complete destruction (less than 5% of its original tensile strength, data not shown), while the GTX with 0.4% of C944 continued to release high amounts of damaged fibres.

SEM analysis showed the degradation suffered by the PP fibres during the UV-exposure tests (Figure 1). After exposition to 35 $MJ.m^{-2}$ of UV radiation, no microscopic damages were found on the GTXs with 0.2% and 0.4% of C944. However, after the exposition to 69 $MJ.m^{-2}$ of UV radiation, both GTXs presented visible signs of degradation, such as transversal fissures along their fibres. As the total UV radiant exposure increased, more damages were continuously found on the PP fibres. For the same total UV radiant energy, the fibres with 0.2% of C944 were always more damaged than the fibres with 0.4% of C944. SEM analysis was not performed for the GTX without C944 (this material was completely destructed).

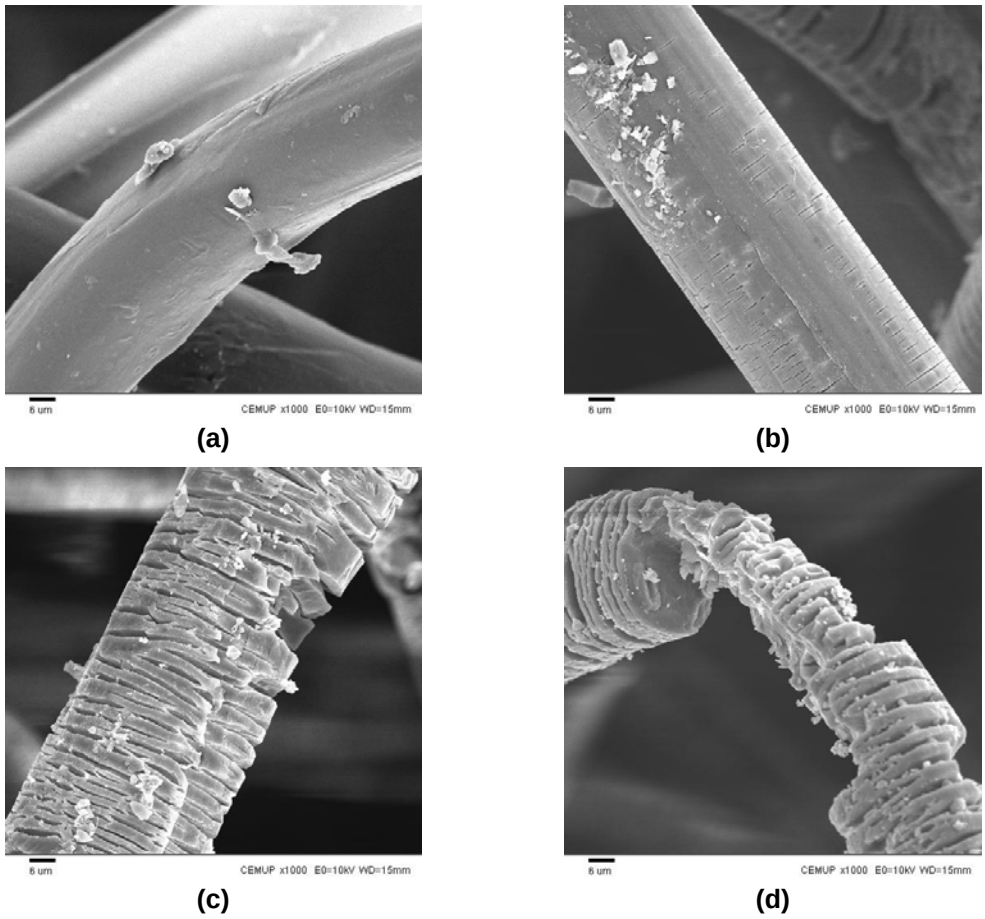

Figure 1 – SEM photographs (x 1000) of the PP fibres stabilised with 0.2% of C944 before (a) and after the exposition to 35 $MJ.m^{-2}$ (b), 69 $MJ.m^{-2}$ (c) and 104 $MJ.m^{-2}$ (d) of UV radiation.

FTIR analysis showed the appearance of a new band (centred at 1720 cm^{-1}) on the infrared spectra of the exposed GTXs (Figure 2). This band, inexistent on the spectra of the reference GTXs (without any UV exposure), indicates the presence of carbonyl groups resulting from the photo-degradation process of PP. The photo-degradation suffered by the GTXs was evaluated by the height of this band (Figure 3).

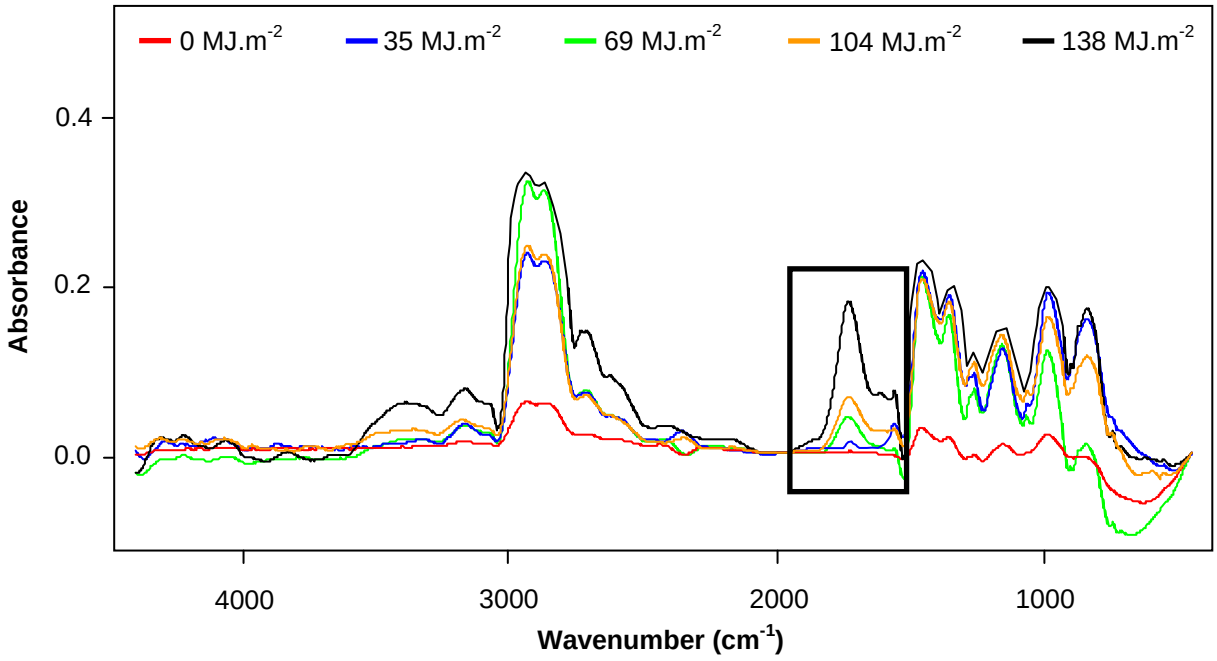

Figure 2 – Infrared spectra of the PP fibres with 0.2% of C944 before and after exposition to UV radiation.

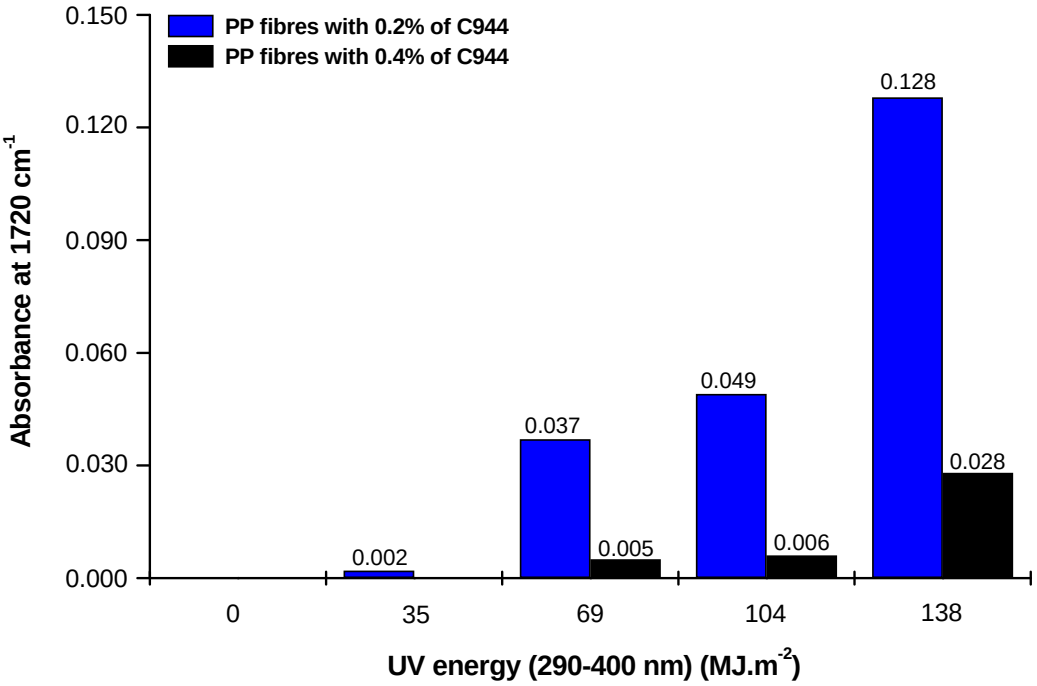

Figure 3 – Evolution of the absorbance (measured at 1720 cm^{-1}) as the PP fibres stabilised with 0.2% of C944 and 0.4% of C944 were exposed to higher total UV radiant exposures.

A small band (absorbance of 0.002 at 1720 cm^{-1}) appeared on the infrared spectra of the PP fibres with 0.2% of C944 after exposition to 35 $MJ.m^{-2}$ of UV radiation. As it can be seen in Figure 3, the intensity of this band increased as the total UV radiant exposure increased. After the exposition of the GTX with 0.2% of C944 to 69 $MJ.m^{-2}$ of UV radiation, this band had already an absorbance of 0.037 at 1720 cm^{-1}, while after 138 $MJ.m^{-2}$ of UV radiation it had an absorbance of 0.128 at 1720 cm^{-1}.

The development of the band centred at 1720 cm^{-1} was more pronounced for the GTX with 0.2% of C944 than for the GTX with 0.4% of C944, showing that the degree of degradation was higher for the fibres with less C944. This way, a better protection of the PP fibres against the damaging effects of UV radiation can be achieved by including a higher amount of C944 on their composition. After exposition to 138 $MJ.m^{-2}$ of UV radiation, the PP fibres with 0.4% of C944 had an absorbance of only 0.028 at 1720 cm^{-1} (in the same conditions, the PP fibres with 0.2% of C944 had an absorbance of almost 4.5 times more).

The results found by infrared spectroscopy were in agreement with the damages observed by SEM and with mechanical results obtained by tensile tests (data not shown). Mechanical results about the resistance of PP GTXs against artificial and natural weathering can be found in Carneiro *et al.* (2006) and in Carneiro *et al.* (2008), respectively.

From the previous results it was possible to conclude that C944 had a very important paper on the protection of the PP fibres against UV radiation. A methodology was developed for the determination of this additive in order to try to understand what happens to C944 while protecting the materials against photo-degradation. Figure 4 shows the evolution of the level of C944 (on the PP fibres with 0.4% of C944) as the total UV radiant exposure increased (the FTIR data is also plotted in the same figure for comparison purposes).

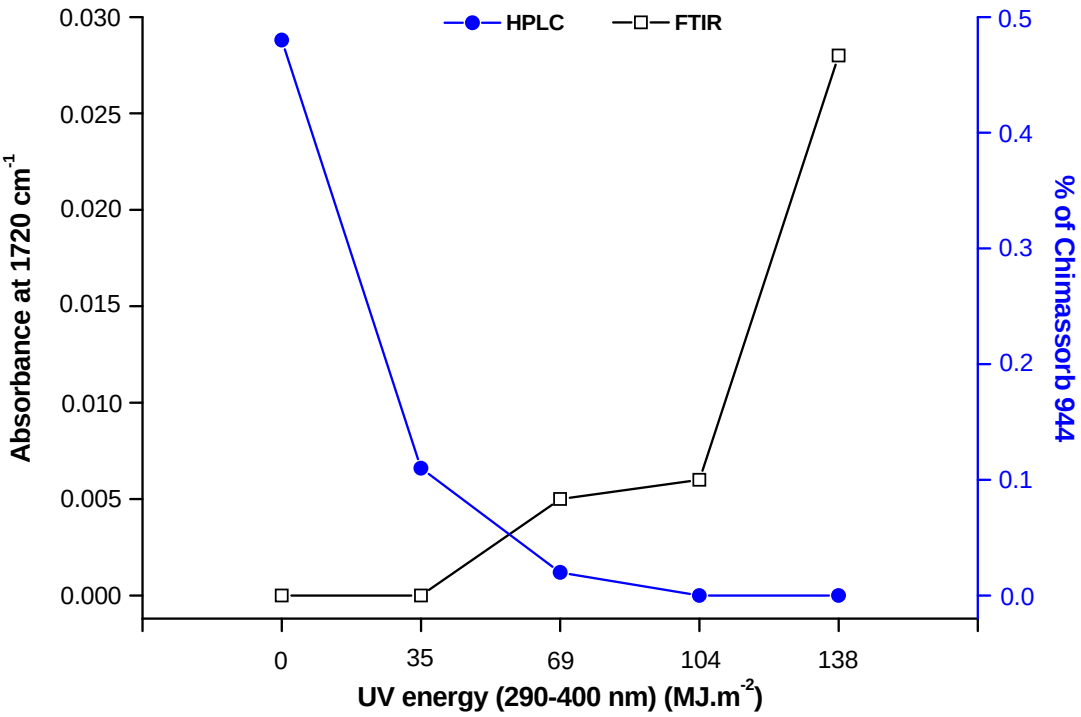

Figure 4 – Evolution of the level of C944 found on the PP fibres *versus* the FTIR absorbance at 1720 cm^{-1} (results for the PP fibres stabilised with 0.4% of C944).

As it can be seen in Figure 4, the level of C944 decreased as the GTX was consecutively exposed to higher amounts of UV energy. After exposition to 35 $MJ.m^{-2}$ of UV radiation, the level of C944 on the PP fibres decreased from 0.48% down to 0.11%, while after 69 $MJ.m^{-2}$ the percentage of C944 present on the fibres was only 0.02%. After exposition to 104 $MJ.m^{-2}$ of UV radiation, the presence of C944 on the PP fibres was not detected. These results indicate that C944 was consumed and/or lost while protecting the GTXs against the harmful effects of UV radiation.

By comparing the FTIR results with the chromatographic results, it was possible to establish a correlation between the degradation suffered by the GTX with 0.4% of C944 and the evolution of the level of the additive on the fibres of this material. As the total UV radiant exposure increased, the level of C944 decreased (leaving the PP fibres successively more vulnerable to suffer UV degradation) and the absorbance at 1720 cm^{-1} increased (indicating successively the existence of more damages on the materials).

4 Conclusions

The durability of the PP GTXs was seriously affected by the exposition to UV radiation; the GTX without C944 was completely destructed (transformed into small pieces or powder), while the GTXs stabilised with 0.2% and 0.4% of C944 suffered serious damages on their structure. SEM analysis showed the appearance of transversal fissures on the PP fibres. As the total UV radiant exposure increased more damages were found on the GTXs stabilised with C944. The GTX with 0.2% of C944 was always more damaged than the GTX with 0.4% of C944, showing that a higher concentration of C944 resulted in a better protection of the materials against UV radiation.

FTIR analyses showed the development of a new band (centred at 1720 cm^{-1}) on the infrared spectra of the PP fibres. This band was used to evaluate the degree of degradation of the PP fibres. By chromatographic analyses, it was possible to observe that the level of C944 on the PP fibres decreased as the total UV radiant exposure increased. C944 was consumed and/or lost while protecting the PP fibres against the damaging effects of UV radiation.

Keywords: Biosorption, orange II, dyes, *Posidonia oceanica*
Topic: Sustainable process-product development through green chemistry. Environmental engineering & management

Abstract

Batch sorption experiments were carried out to remove orange II from aqueous solutions using *Posidonia oceanica* non living leaves. The effect of sorbent particle size, biosorbent dose and pH on the dye uptake was studied. The kinetics of orange II adsorption have been investigated at different temperatures. Sorption data were fitted to pseudo-first order, pseudo-second order and Elovich kinetic models. The results showed that no significant differences in adsorption capacity exit with particle size from <0.15 to 2.5-3.2 mm. When the adsorbent dose increased the percentage of dye sorption increased accordingly. Color removal was maximum at an acid pH of 1, and decreased when pH value rised. The kinetic data were found to follow pseudo-second order kinetic and revealed that the sorption capacity increased when the temperature decreased from 40ºC to 10ºC.

1 Introduction

Synthetic dyes are extensively used in many industries such as textile, paper, printing, leather tanning, food technology, hair colorings, etc. There are over 100000 commercially available dyes and two per cent of dyes produced are discharged directly in aqueous effluent. The presence of very small amounts of dyes in wastewater is highly visible, and many of these dyes are toxic, carcinogenic and present a serious hazard to aquatic living organisms (Aksu, 2005).

Several physical, chemical and biological methods for dye removal have been reported: coagulation-flocculation, membrane separations, oxidation process, ion-exchange, adsorption, etc. Activated carbon adsorption is an extended procedure, but this sorbent is expensive. In last years many non-conventional low cost adsorbents, including natural materials, have been used for dyes removal (Crini, 2006).

In this work the adsorption potential of dead biomass of *Posidonia oceanica* (inexpensive material abundant in the beaches of the Mediterranean Sea) for orange II removal is evaluated. The effect of sorbent particle size, biosorbent dose and pH on the dye uptake was studied. The kinetics of orange II adsorption have been investigated at different temperatures. Sorption data were fitted to pseudo-first order, pseudo-second order and Elovich kinetic models

2 Materials and methods

2.1. Biosorbent material

Non living leaves of *Posidonia oceanica* were collected from the beaches of Mediterranean Sea at the Region of Murcia, washed repeatedly with tap water to

* Corresponding author. Tel:+34 968367360. E-mail: jfortuno@um.es

remove sand and salt and dried in an oven at 50-60ºC. This material was ground and sieved to obtain various size fractions.

2.2. Dye and chemicals

An azo dye, orange II (Acid orange 7) provided by Sigma, was used without further purification and stock solution of 1000 mg·L^{-1} was made with distilled water. Experimental solutions were prepared by diluting the stock solution with distilled water when necessary. HNO_3 and NaOH used to adjust pH were of analytical grade and supplied by PANREAC.

2.3. Sorption experiments

Batch sorption experiments were carried out in glass flasks at desired temperature, using a constant temperature bath. Biomass and orange II solutions of known concentrations were brought into contact by magnetic stirring. The pH of the solutions was controlled using HNO_3 or NaOH dilute solutions. After the desired contact time, samples were collected and then centrifuged. The dye residual concentration in the supernatant solutions was determined using a UV spectrophotometer (Shimadzu UV-1603) measuring their absorbance at maximum absorbance wavelength (λ= 485 nm). Calibration curve was obtained with standard solutions. The amount of dye adsorbed was found by mass-balance procedure.

2.3.1. Effect of sorbent particle size

In this study 50 mL of dye solution of 100 mg·L^{-1} was agitated with 0.2 g of biosorbent (adsorbent dose 4 g·L^{-1}) at pH 2 and 25ºC. The used sorbent particle sizes were: < 0.15 mm, 0.15-0.3 mm, 0.3-0.5 mm, 0.5-0.8 mm, 0.8-1.0 mm, 1.0-1.5 mm, 1.5-2.5 mm, 2.5-3.2 mm and 0.5-2.5 mm. Agitation was made for 24 h which is more than sufficient to reach equilibrium.

2.3.2. Effect of sorbent dosage

Different quantities of biomass (particle size fraction 0.5-2.5 mm), from 0.025 to 1.0 g, were shaken for 24 h, at 25ºC and pH 2, with 100 mL of dye solution (100 mg·L^{-1}).

2.3.3. Effect of pH

The effect of pH on amount of color removal was analyzed over the pH range from 1 to 12. The pH was adjusted using NaOH and HNO_3 dilute solutions. 50 mL of dye solution of 100 mg·L^{-1} was agitated with 0.2 g of biosorbent at 25ºC. The particle size fraction used was 0.5-2.5 mm. The contact time was 24 h.

2.3.4. Sorption kinetics

Batch kinetic experiments were carried out by agitating 500 mL of dye solution (initial concentration 100 mg·L^{-1}) with 2 g of biosorbent in 1 L glass beakers. Samples were pipetted out at different time intervals, centrifuged and analyzed for residual dye concentration. Experiments were performed at the desired temperature (10, 25 and 40ºC) using particle size of 0.5-2.5 mm and pH 2.

The prediction of batch sorption kinetics is necessary for the design of industrial sorption equipments. Several kinetics models have been proposed in order to predict the mechanism involved in the sorption process. Kinetic experimental data have been adjusted to pseudo-first order, pseudo-second order and Elovich kinetics models (Ho and McKay, 1998) by non linear regression.

Pseudo-first order equation

The pseudo-first order equation is generally expressed as follows:

$$\frac{dq}{dt} = k_1 \cdot (q_e - q)$$

After integration and applying the boundary conditions, for q=0 at t=0 and q=q at t=t, the equation becomes:

$$q = q_e \cdot (1 + e^{-k_1 \cdot t})$$

where q_e and q ($mg \cdot g^{-1}$) are the amount of dye sorbed at equilibrium and at time t, respectively, and k_1 (min^{-1}) is the rate constant of pseudo-first order equation.

Pseudo-second order equation

The pseudo-second rate order equation is expressed as:

$$\frac{dq}{dt} = k_2 \cdot (q_e - q)^2$$

Integrating this equation for the boundary conditions, gives:

$$q = \frac{t}{\frac{1}{k_2 \cdot {q_e}^2} + \frac{t}{q_e}}$$

where k_2 is the pseudo-second order rate constant ($g \cdot mg^{-1} \cdot min^{-1}$) and $h = k_2 \cdot {q_e}^2$ where h ($mg \cdot g^{-1} \cdot min^{-1}$) is the initial sorption rate.

Elovich equation

Elovich equation is of general application to chemisorption kinetics. The equation has been applied satisfactorily to some chemisorption processes and has been found to cover a wide range of slow adsorption rates. The same equation is often valid for systems in which the adsorbing surface is heterogeneous, and is formulated as:

$$\frac{dq}{dt} = \alpha \cdot e^{-\beta \cdot q}$$

Integrating this equation for the boundary conditions, gives:

$$q = \frac{1}{\beta} \cdot \ln(\alpha \cdot \beta) + \frac{1}{\beta} \cdot \ln t$$

where α ($mg \cdot g^{-1} \cdot min^{-1}$) is the initial sorption rate and β is related to the extend of surface coverage and activation energy for chemisorption ($g \cdot mg^{-1}$).

3 Results and discussion

3.1. Effect of sorbent particle size

In Figure 1 can be observed that no significant differences in adsorption capacity (q_e) for orange II exit with particle size fractions from <0.15 to 2.5-3.2 mm (q_e varies between 9.8 – 11.7 $mg \cdot g^{-1}$ adsorbent). This fact may be due to the small thickness of the *Posidonia oceanica* leaves, which favours diffusion processes.

3.2. Effect of sorbent dosage

Figure 2 shows the effect of biosorbent dose on the percentage of color removal and on biomass sorption capacity. As can been expected, the percentage of dye removal increased with the increasing biomass concentration. Thus, an increase in the dose of adsorbent from 0.25 to 4 g/L increased appreciably the removal of orange II from 8% to 55%. A greater dose increases the removal of dye in lower extent. However, the adsorption capacity (q_e) decreased with the increasing in biomass concentration.

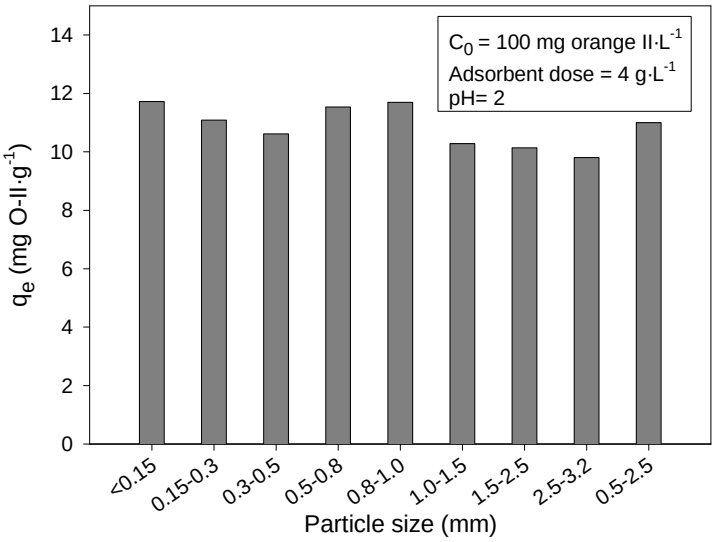

Figure 1.- Effect of particle size

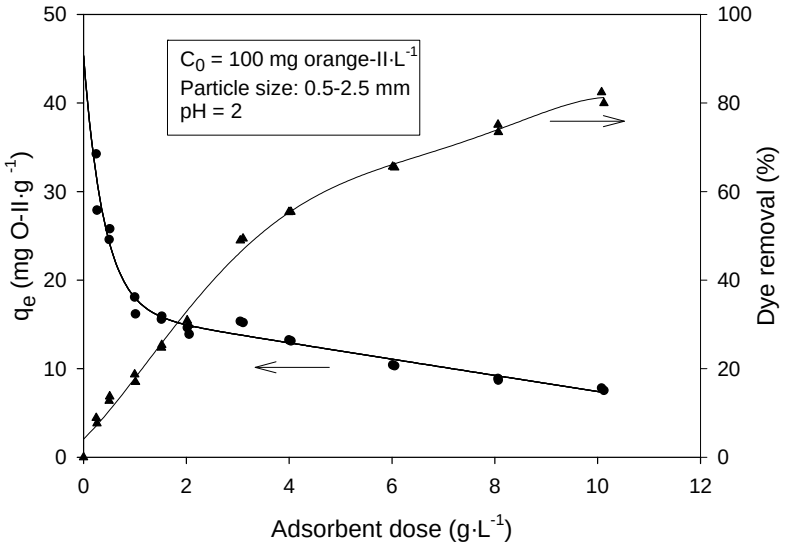

Figure 2.- Effect of adsorbent dose

3.3. Effect of pH

The pH is one of the most important factors controlling the adsorption of dye onto biosorbent. Figure 3 shows the extent of dye removal at different pH values from 1 to 12. The removal of dye was the greatest at pH 1 (q_e=16 mg·g^{-1}) and decreased significantly when pH increased from pH 1 to 12. At pH>6 the q_e value was small (< 5 mg·g^{-1}), and was near 0 at pH 12. At acidic pHs the sorbent surface acquire positive charge due to the excess of protons in solution. Thus, the electrostatic attraction between the negatively charged adsorbate species and the positively charged adsorbent particles increases.

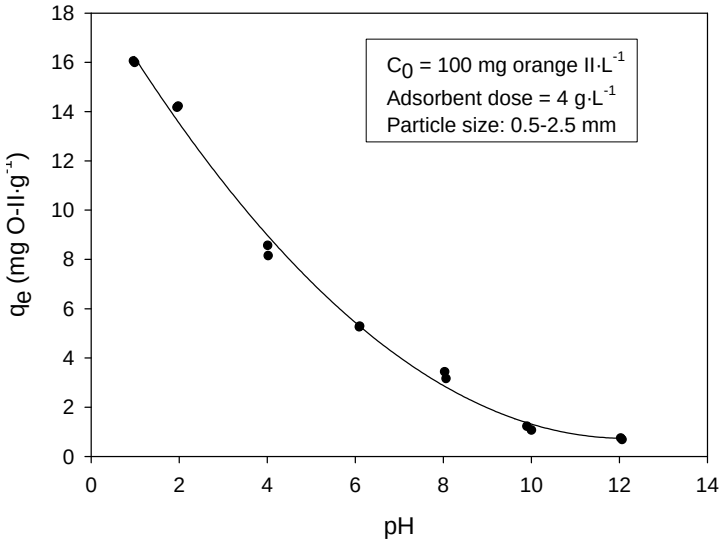

Figure 3- Effect of pH

3.4. Sorption kinetics

Figure 4 shows a plot of the amount of dye adsorbed (q, mg·g^{-1}) versus contact time for different experimental temperatures (10, 25 and 40ºC). The removal of orange II by adsorption on *Posidonia oceanica* leaves increased with contact time at all temperatures. A two-staged kinetic behavior is evident: a rapid initial adsorption occurred during the first hours, followed by a long period of much slower uptake. The higher sorption rate at the initial period (first 120 min) may be due to the great number of surface vacant sites available at this stage. Therefore, the concentration gradient between adsorbate in solution and adsorbate in the adsorbent surface is high. As time proceeds this gradient is reduced due to the accumulation of dye in the sorption sites, leading to a decrease in sorption rate at later stage. The equilibrium was reached before 24 h of contact time at all temperatures studied.

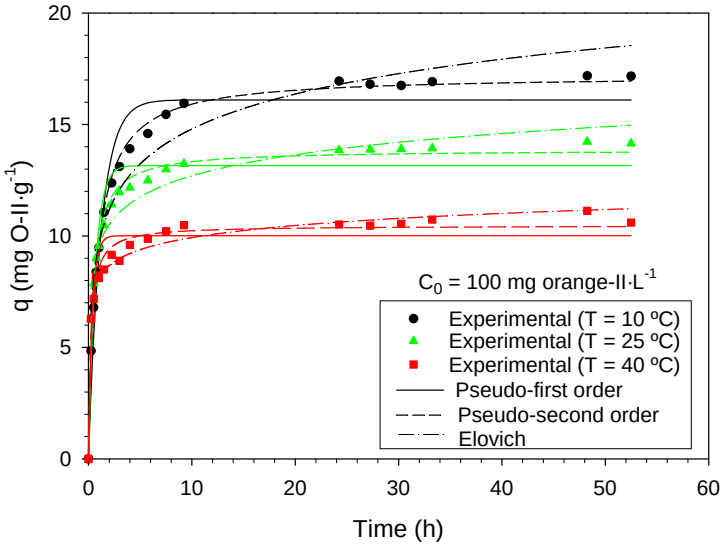

Figure 4.- Kinetics of orange II adsorption

The temperature dependence of orange II sorption is shown in Figure 4. The results revealed that the sorption capacity decreased from 17 to 11 $mg \cdot g^{-1}$ when the temperature of dye solutions increased from 10 to 40ºC. However, the sorption initial rate increased from 0.36 to 0.77 $mg \cdot g^{-1} \cdot min^{-1}$ when the temperature increased from 10 to 40ºC.

Figure 4 shows the theoretical curves obtained by fitting experimental data to pseudo-first order, pseudo-second order and Elovich kinetic models by non linear regression. The characteristic parameters of the different kinetic models employed to study the dynamic of the orange II uptake are tabulated in Table 2. The pseudo-second order equation provides the best correlation for all of the experimental data

Table 1. Characteristic parameters of the different kinetic models

		Temperature (ºC)		
		10	**25**	**40**
Pseudo-first order	**q_e ($mg \cdot g^{-1}$)**	15.8	13.0	10.0
	k_1 (min^{-1})	0.016	0.029	0.044
Pseudo-second order	**q_e ($mg \cdot g^{-1}$)**	17.3	13.9	10.5
	k_2 ($g \cdot mg^{-1} \cdot min^{-1}$)	0.001	0.003	0.007
	h ($mg \cdot g^{-1} \cdot min^{-1}$)	0.36	0.58	0.77
Elovich equation	**α ($mg \cdot g^{-1} \cdot min^{-1}$)**	1.75	19.9	421
	β ($mg \cdot g^{-1}$)	0.41	0.72	1.28

Keywords: Biosorption, methylene blue, packed bed, *Posidonia oceanica*
Topic: Sustainable process-product development through green chemistry. Environmental engineering & management

Abstract

A continuous up-flow fixed bed study was carried out by using *Posidonia oceanica* non living leaves as a biosorbent for the removal of methylene blue (MB) dye from aqueous solution. The effect of process variables, such as bed depth (6.64, 11.6 and 18 cm) and solution flow rates (11.5, 16.5 and 21.5 $mL \cdot min^{-1}$), on the sorption characteristics of sorbent was investigated. The experimental breakthrough curves were obtained. Experimental data confirmed that the breakthrough time and amount of sorbed dye increased with increasing the bed depth and decreased with increasing flow rate. Bed depth service time (BDST), Thomas, Clark and Yoon-Nelson models were used to describe the breakthrough curves and to determine the characteristic parameters of the column, useful for process design. All these models showed a good correlation between the experimental data and the model-calculated breakthrough curves.

1 Introduction

For decades, dyes and pigments have been used for coloring in the industry. Several types of dyes are available for usage with various types of materials. Among these many types, cationic dyes, commonly known as basic dyes, are widely used in acrylic, nylon, silk and wool dying. In textile dying processes, a large volume of dye-contaminated effluents are discharged, and it was estimated that 10-15% of the dye is lost in the effluent. The presence of dyes in the effluents could be highly undesirable. Consequently, the removal of these compounds from effluents is required to decrease their impact on the environment. This is usually achieved through physico-chemical means, since dyes are relatively resistant to microbial degradation due to their complicated structures. Activated carbon adsorption is an extended removal procedure, but this sorbent is expensive. In last years many non-conventional low cost adsorbents, including natural materials, have been used for dye removal (Aksu, 2005).

Results obtained in previous studies carried out in batch mode showed that *Posidonia oceanica* non living leaves biomass was able to remove methylene blue from aqueous solutions by biosorption (Ortuño et al., 2006). The biomass contains, among others, phenolic, carboxylic and hydroxyl functional groups, useful for binding dyes.

Fixed-bed adsorption systems are widely used to remove contaminants from wastewater because present numerous advantages. It is simple to operate, can provide continuous treatment with a long breakthrough time, gives high yields and can be easily scaled up from laboratory experiments, often used to obtain design information and to predict column performance. The performance of packed beds is usually described by means of breakthrough curves, where the ratio of the effluent concentration to the influent

* Corresponding author. Tel +34 968367360. E-mail: jfortuno@um.es

concentration is plotted against the service time of the column.

The aim of this study was to investigate the influence of flow rate and bed depth on the performance of methylene blue biosorption onto *Posidonia oceanica* non living leaves in an up-flow packed bed column. Several simplified models were applied to the experimental data to simulate the breakthrough curves in order to predict the scale-up of a unit plant.

2 Materials and methods

2.1. Biosorbent material

Posidonia oceanica non living leaves were collected from the beaches of Mediterranean Sea at the Region of Murcia (southeast Spain). They were washed with tap water to remove impurities and dried in an oven at 60ºC. Dry biomass was crushed and sieved to a particle size of 0.5–2.5 mm.

2.2. Chemicals

The column feed solution of methylene blue (20 mg MB·L^{-1}, pH = 6.0) was prepared by dissolving the neccesary quantity of MB-trihydrated, provided by Sigma-Aldrich, in distilled water.

2.3. Column

Continuous-flow sorption experiments were conducted in a fixed bed column packed with biosorbent material. The column was made of a methacrylate tube of 2.2 cm internal diameter. At the bottom of the column, a plastic sieve was fixed, then a layer of glass balls (3 mm diameter) was placed in order to provide a uniform inlet flow of solution into the bed. A weighed amount of adsorbent, depending on the bed depth (6.64, 11.6 or 18 cm), was put within the column between teflon adsorbent-retaining sieves, and then an upper layer of glass balls was placed on top of the bed. The ratio sorbent weight/bed depth was 0.6 g·cm^{-1} (0.158 g·cm^{-3}).

2.4. Experimental procedure

The dye solution was pumped by a peristaltic pump (Watson Marlow 505 Du) vertically upward through the column to avoid channeling due to gravity and to enhance uniform distribution of solution throughout the bed. The desired flow rate (11.5, 16.5 or 21.5 mL·min^{-1}) was maintained constant during each experiment and checked periodically by collecting solution at the outlet for a given time and weighing the amount collected. Samples from column effluent were collected periodically by an automatic fraction collector until the dye concentration exceeded a value of 19.9 mg·L^{-1}. The dye concentrations were determined using a UV-VIS spectrophotometer (Shimadzu UV-1603) by measuring the absorbance of solutions at their maximum absorbance wavelength (664 nm) and using a calibration curve. This procedure enabled the breakthrouhg curves to be obtained. The pH values of the effluent samples were recorded.

2.5. Modeling of column data

The performance of packed beds is described through the breakthrough curve. Several characteristic parameters, determined by using the breakthrough curve may be used to evaluate the performance of the fixed bed. Breakthrough and exhaustion times were defined at relative effluent concentration C/C_0 of 0.05 and 0.95, respectively. The quantity of dye retained in the column, represented by the area above the breakthrough curve, was obtained through numerical integration. Sorption capacity (q_{ads}) was defined as total amount of dye sorbed per gram of sorbent at the end of total flow time.

Several simplified fixed bed models have been developed to predict the behaviour of the adsorption bed and to describe the breakthrough curves. Bed depth service time (BDST), Thomas, Clark and Yoon-Nelson models (Aksu and Gönen, 2004) are used in this work (Table 1).

Table 1. Simplified fixed-bed breakthrough curve models.

Mathematical models	Equation	Parameters
BDST	$\frac{C}{C_0} = \frac{1}{\left(e^{\left(K_a N_0 H / v\right)} - 1\right) \cdot e^{-K_a C_0 t} + 1}$	K_a, kinetic constant ($L \cdot mg^{-1} \cdot h^{-1}$). N_0, volumetric sorption capacity of bed ($mg \cdot L^{-1}$)
Thomas	$\frac{C}{C_0} = \frac{1}{1 + \exp\left(\frac{K_{Th}}{Q}\left(q_0 \cdot X - C_0 \cdot V_{eff}\right)\right)}$	K_{Th}, kinetic constant ($L \cdot mg^{-1} \cdot h^{-1}$) q_0, equilibrium sorption capacity, ($mg \cdot g^{-1}$) X, sorbent amount in the column
Clark	$\frac{C}{C_0} = \left(\frac{1}{1 + A \cdot e^{-r \cdot t}}\right)^{\frac{1}{n-1}}$	A, constant of the Clark model r, adsorption rate (h^{-1}) n, Freundlich adsorption constant
Yoon-Nelson	$\ln\left(\frac{C}{C_0 - C}\right) = K_{YN} \cdot t - \tau \cdot K_{YN}$	K_{YN} , kinetic constant (h^{-1}) τ, time when $C = 0.5 \cdot C_0$ (h)

Experimental column data were fitted, by non linear regression, to each model equation. The model parameter values were determined by minimising the average relative error (ARE) function using the Solver add-in with Microsoft spreadsheet, Excel. The ARE function is described as follow, where *n* is the number of experimental data to fit:

$$ARE\ (\%) = \frac{100}{n} \sum_{i=1}^{n} \left| \frac{\left(\left(C/C_0\right)_{\exp} - \left(C/C_0\right)_{calc}\right)}{\left(C/C_0\right)_{\exp}} \right|$$

3 Results and discussion

Experimental breakthrough curves are shown in Figure 1. Breakthrough time (t_b) and sorption capacity of fixed bed (q_{ads}) were evaluated from experimental data and they are included in Table 2.

3.1. Effect of flow rate

The effect of flow rate (11.5, 16.5 and 21.5 $mL \cdot min^{-1}$) was studied for constant bed height (11.6 cm) (Figure 1a and Table 2). As the flow rate through the bed increases, the breakthrough curve becomes steeper and the breakthrough time decreases. Usually, the adsorption capacity decreases at higher flow rates, because MB biosorption is affected by insufficient residence time of the solute in the column (insufficient contact time between the dye and the sorbent) and because the diffusion of the solute into the pores of biosorbent is limited. An increase in the flow rate reduces the volume treated efficiently until breakthrough point and therefore decreases the service time of the bed.

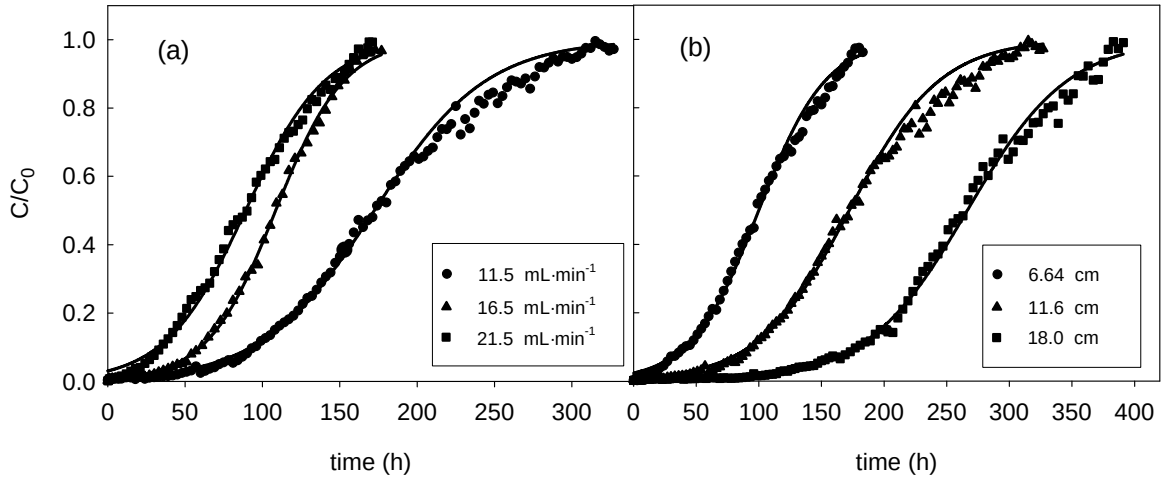

Figure 1. Breakthrough curves. Experimental data (symbols) and predictect by BDST model (lines) (C_0 = 20 mg/L, pH_0 = 6.0). (a) H = 11.6 cm; (b) Q = 11.5 mL/min.

Table 2. Experimental and models parameters. (Units: Q: $mL \cdot min^{-1}$; H: cm; t_b and τ: h; q_{ads} and q_0: $mg \cdot g^{-1}$; K_a and K_{Th}: $L \cdot mg^{-1} \cdot h^{-1}$; N_0: mg/L; r and K_{YN}: h^{-1}).

		Experimental		BDST		Thomas		Clark		Yoon-Nelson	
Q	H	t_b	q_{ads}	$K_a \cdot 10^3$	$N_0 \cdot 10^{-3}$	K_{Th}	q_0	r	A	K_{YN}	τ
	6.64	25	337	1.87	54.1	1.87	345	0.022	0.226	0.037	100.0
11.5	11.6	72	341	1.38	53.1	1.36	341	0.016	0.367	0.027	172.9
	18	146	387	1.24	52.8	1.24	368	0.014	0.950	0.025	266.5
11.5		72	341	1.38	53.1	1.36	341	0.016	0.367	0.027	172.9
16.5	11.6	45	288	2.26	47.94	2.26	307	0.025	0.368	0.045	108.5
21.5		23	314	1.94	51.67	1.94	328	0.024	0.182	0.039	89.1

3.2. Effect of the bed height

Figure 1b shows the breakthrough curves for different bed depths. As expectable, breakthrough time (t_b) and dye sorbed quantity are higher as the bed height increases (Figure 1b and Table 2) due to the increase in adsorbent amount in larger beds, which provide greater service area and adsorption sites.

3.3. Modeling of column data

The four simplified models showed in Table 1 were applied to experimental data for the description of the beakthrough curves and to determine the model parameters. The values of the model parameters, calculated by non-linear regression, are given in Table 2. The average relative error (ARE), between the experimental and model predicted values of C/C_0, was used to compare the goodness of the theoretical models to describe experimental data. All of these models provide good approximations to the experimental behaviour (ARE values lower than 11%), describing adequately the experimental breakthrough curves. Figure 1 shows experimental (points) and BDST model predicted (lines) breakthrough curves.

In order to compare the experimental and model calculated values of breakthrough time (t_b), the time at which $C = 0.5 \cdot C_0$ (t_0) and sorption capacity (q_{ads}), calculated values of t_b, t_0 and q_{ads} were plotted vs experimental ones. It was observed that the experimental values of these parameters do not differ significantly from model calculated ones.

3.4 Column effluent pH

Effluent pH values were recorded at the exit of the column. As shown in Figure 2, outlet pH values were, initially, higher than those in feed solution and later decrease until the inlet value. This may be explained as sorption of hydrogen ions on sorbent surface or because of the dissolution of alkaline compounds from the sorbent.

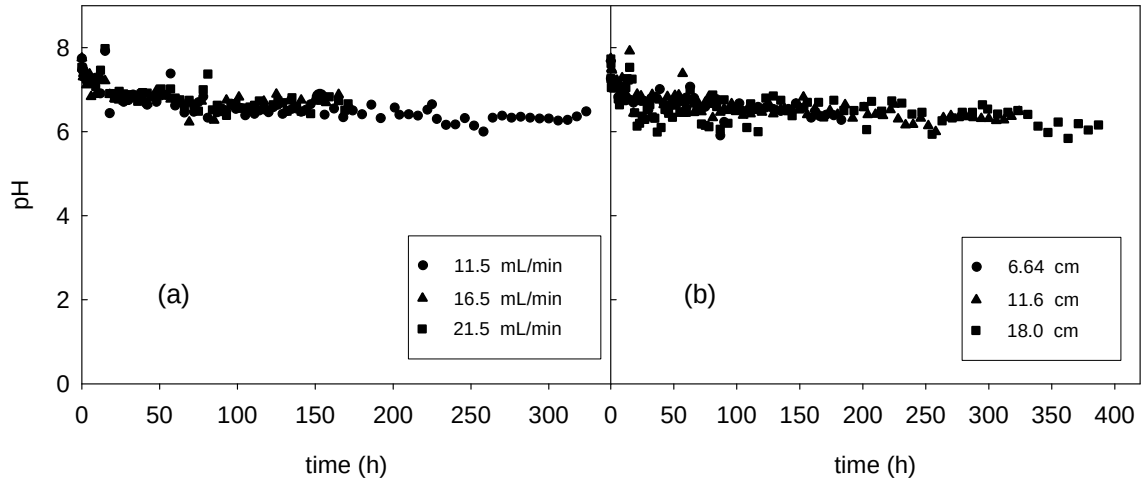

Figure 2. Effluent pH values (C_0 = 20 mg/L, pH_0 = 6.0). (a) H = 11.6 cm; (b) Q = 11.5 mL/min.

4 Conclusion

The sorption of methylene blue by *Posidonia oceanica* non living leaves in a fixed-bed column was studied. The experimental results showed that this biomass removes the dye effectively and its adsorption capacity depends on the column operating parameters (flow rate and bed height). The experimental breakthrough curves can be predicted adequately using the BDST, the Thomas, the Clark and the Yoon-Nelson models. These models can be used to simulate the scaling-up of a unit plant.

Optimization of Chromium adsorption upon chitosan by surface response analysis

Andelib Aydın*, Nuran Deveci Aksoy, Bayram Andak
ITU – Istanbul Technical University, Chemical Engineering Department, Ayazaga Campus, 34469 Istanbul, Turkey.

Keywords: Chromium adsorption, Experimental design, Optimization, Chitosan
Topic: Sustainable process-product development through green chemistry

Abstract

The adsorption of Cr^{6+} upon chitosan flakes was investigated as function of pH, adsorbent dose and initial concentration. The effects of these factors were studied in the ranges 1.5-9.5, 1.8-24.2 g/L and 15-95 mg/L, respectively. Surface response methodology was involved in the design of experiments and also optimization studies. Maximum removal was attained from a solution as concentrated as 30 ppm at pH 3 with an adsorbent dosage of 13 g/L. The adsorption capacity of chitosan flakes was determined as 22.09 mg/g. Adsorption data was found to correlate best with Freundlich isotherm with 99.5% consistency. The Freundlich isotherm parameters K_F and n were calculated as 2.79 and 1.7, respectively.

1 Introduction

The continuously increasing demand for the commodities produced by chemical industries has triggered heavy metals accumulation in the ecosystem. Chromium is discharged to the environment, well above trace limits, as a result of electroplating, leather tanning, cement preservations, paints, pigments, textile, steel fabrication and canning industries. There exist two stable oxidation states for Chromium in nature, Cr^{3+} and Cr^{6+}. The latter of species is known to be highly mobile in soil and aquatic system, and is also more toxic, mutagenic and carcinogenic (Dubey and Gopal, 2007).

Conventional methods applied for Cr^{6+} removal are chemical precipitation, oxidation/reduction, filtration, ion exchange, membrane separation and adsorption. Chemical precipitation produces great amounts of mud, whilst ion exchangers and membrane separation are relatively of very high cost (Nomanbhay and Palanisamy, 2005). Therefore, adsorption is the most frequently applied technique owing to its advantages such as variety of adsorbent materials and high efficiency at a relatively lower cost (Babel and Kurniawan, 2003). Recently, the removal of metals, compounds, and particulates from solution by biological material is recognized as an extension to adsorption and is named as biosorption (Boddu et al., 2003). Many biosorbents such as algae (Gupta et al., 2001), seaweeds (Kratochvil et al., 1998) and biopolymers (Bailey et al., 1998) have been utilized in the removal of heavy metals from wastewater.

Chitosan, the major derivative of chitin, and second abundant biopolymer in nature after cellulose, is a good scavenger for metal ions owing to the amine and hydroxyl functional groups in its structure (Zhao et al., 2007). The formerly conducted studies considering the adsorption of Cr^{6+} have proved that the process parameters, namely, pH, initial concentration, temperature, adsorbent dose and particle diameter influence the removal efficiency immensely (Rojas et al., 2005). This influence can be realized by inspection of the reported values for Cr^{6+} adsorption capacity of chitosan which varies from 27.3 mg Cr^{6+}/g (Bailey et al., 1999) to 273 mg Cr^{6+}/g (Babel and Kurniawan, 2003). The confusion about adsorption capacity could be overcome by optimization of the parameters involved. Therefore, this study aimed to investigate the effects of process parameters on the Cr^{6+}

* Corresponding author. Tel + 90-212-2856878. E-mail:erdoganyas@itu.edu.tr

adsorption capacity of chitosan and to determine the set of parameters leading to maximum Cr^{6+} removal. The effects of pH, initial concentration and adsorbent dose were studied, while the efffects of temperature and particle diameter were excluded intentionally. Surface responce methodology was utilized for optimization studies.

Classical methods of optimization involve the change of one variable at a time which is quite time consuming especially when a large number of variables are considered. Alternatively, response surface methodology aims to optimize the response surface shaped under the influence of the process parameters.

2 Materials and Methods

2.1 Reagents

Chitosan flakes (low molecular weight) of deacetylation degree of minimum 85.0% were obtained from Sigma. Extra pure potassium dichromate, 37.0% pure HCl, and analysis grade 1,5-diphenyl carbazide were purchased from Merck. Sodium hydroxide (≥98.0%), nitric acid (65.0%), and sulphuric acid (95-97%) were obtained from Fluka. Acetone (99.0%) used in preparation of 1,5-diphenyl carbazide solution was purchased from Carlo Elba. Deionized water was involved in preparation of all solutions as well as rinsing of glassware.

2.2 Design of Experiments

Central composite design was employed in the experimental design procedure. The total number and sequence of experimental runs were determined using the MINITAB software. According to this design, 20 experiments were conducted with three replications each to ensure the accuracy of the results. The effects of process parameters pH, ion concentration and adsorbent dosage were investigated at five levels as summarized in Table 1. Significance level (α) was chosen as 0.05.

Table 1. Lower and upper bounds of the parameters

Parameters	Coded Value				
	-1.6	**-1**	**0**	**1**	**1.6**
pH	1.5	3	5.5	8	9.5
Initial concentration (mg/L)	15	30	55	80	95
Adsorbent Dose (g/L)	1.8	6	13	20	24.2

Surface plots were constructed by using MINITAB. Main effects and interactions of the factors were determined by fitting a second order polynomial equation (Eq.1) and by interpretation of the ANOVA table. A variable is considered significant when the calculated probability value (p) is smaller than the chosen significance level. In case of insignificance the variable is omitted from the model.

$$y = \beta_0 + \sum_{i}^{k} \beta_i x_i + \sum_{i}^{k} \beta_{ii} x_i^2 + \sum_{i} \sum_{j} \beta_{ij} x_i x_j + \varepsilon \quad (1)$$

Here, y is the predicted response, i and j take value from 1 to the number of independent process variables. The β values are coefficients predicted by the method of least squares, ε is the error of prediction and x_i and x_j are the level of the independent process variables (Palanikumar and Karthikeyan, 2006). The responce surface plots constructed by the aid of predictive model were used in determination of the optimum values of the process variables leading to maximum removal percentage.

2.3 Adsorption Experiments

Stock Cr^{6+} solution of 500 ppm was prepared using $K_2Cr_2O_7$ with deionized water. For further experiments, solutions of 50 mL volume were prepared by dilution of this stock. Batch tests were conducted in 100 mL stoppered flasks in a water bath kept at 298K. Agitation rate was

held constant at 120 rpm. The required time to reach equilibrium was determined as 24 hours by preliminary experiments. The pH of the solutions were regulated by micro additions of 0.2N H_2SO_4 and 0.1N NaOH. For the development of isotherms, 5 g/L beads were placed in chromium solutions of varying concentration. Diphenyl carbazide method was used for analysis of Cr^{6+} concentration of solutions.

3 Results and Discussion

3.1 Data Analysis and Construction of Model

The sequence of experiments and summary of the results are given in Table 2. The removal percentages listed in the fifth column are averages of three parallel experiments and they are calculated according to Eq.(2).

$$\text{Removal \%} = \frac{C_0 - C_e}{C_0} * 100 \quad (2)$$

where C_0 and C_e are the initial and equilibrium concentration of solutions (mg/L), respectively. Removal percentage values were recorded as the responce of the system and the values were used in creating the surface plots as shown in Figures 1-3.

Table 2. Calculated results for adsorption of Cr(VI) on chitosan.

Experiment No.	Initial Concentration	Adsorbent Dose	pH	Removal (%)
1	-1.0	-1.0	-1.0	84.18
2	1.6	0.0	0.0	88.47
3	0.0	1.6	0.0	78.42
4	0.0	0.0	0.0	93.12
5	0.0	0.0	0.0	76.89
6	0.0	0.0	0.0	93.36
7	0.0	0.0	1.6	84.71
8	-1.6	0.0	0.0	59.99
9	0.0	0.0	-1.6	85.52
10	-1.0	1.0	-1.0	72.38
11	1.0	1.0	1.0	84.98
12	-1.0	-1.0	1.0	64.42
13	0.0	-1.6	0.0	96.07
14	0.0	0.0	0.0	80.69
15	0.0	0.0	0.0	59.77
16	1.0	1.0	-1.0	92.81
17	-1.0	1.0	1.0	96.56
18	1.0	-1.0	1.0	82.84
19	1.0	-1.0	-1.0	64.11
20	0.0	0.0	0.0	82.03

Variance analysis conducted for full quadratic model including all linear, square and interaction terms proved that the interaction and square terms other than the square effect of pH had very poor effect on the adsorption of Cr^{6+}. Although the regression coefficient of this model was quite high (0.93), a large difference was observed with the adjusted regression coefficient (0.86). When insignificant terms were excluded from the model, the regression coefficient happened to drop to 0.90; however, adjusted regression coefficient increased to 0.87. Both the narrowed gap between the regression coefficients and the decreased standard deviation were accepted as indications of enhanced strength of the model. The ANOVA table for the final model given in Eqn. 3 is provided in Table 3.

$$\text{Removal (\%)} = 83.555 - 11.783*\text{pH} - 3.55*C_0 + 3.353*\text{Adsorbent dose} - 3.795*\text{pH}^2 \quad (3)$$

Table 3. Analysis of Variance for the final model.

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Regression	4	2314.31	2314.31	578.578	32.80	0.000
Linear	3	2134.32	2134.32	711.441	40.33	0.000
Square	1	179.99	179.99	179.988	10.20	0.006
Residual Error	15	264.61	264.61	17.640	8.82	0.013
Lack-of-Fit	10	250.41	250.41	25.041		
Pure Error	5	14.20	14.20	2.840		
Total	19	2578.92				

The outcomes of variance analysis were used to evaluate the intensity of the effects of process conditions. The probability values were calculated as 0.000, 0.008, and 0.011 for pH, initial concentration and adsorbent dosage, respectively. Since all p values were lower than significance level, all parameters were effective on the extent of adsorption at main effect levels. However, the order of effectiveness for main effects was determined as pH>initial concentration>adsorbent dose.

3.2 Surface and Contour Plots

Surface and contour plots were used in determination of the optimum set of process conditions. The surfaces constructed under the combined effect of process parameters are shown in Figures 1-3.

The combined effect of pH and initial concentration is shown in Figure 1. Accordingly, when pH was held in the acidic region, preferably below pH<3, over 90% removal was attained for solutions concentrated up to 70 mg/L.

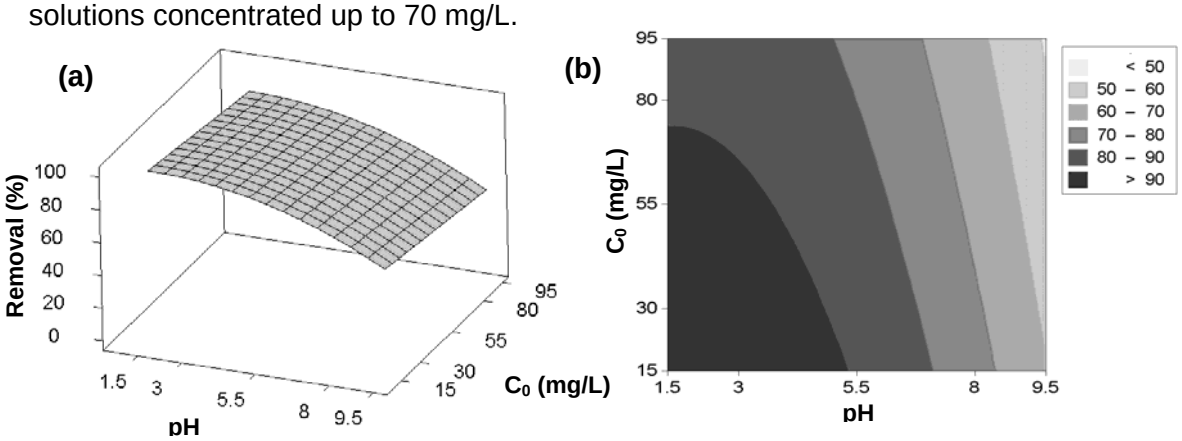

Figure 1. (a) Surface, **(b)** contour plot for pH-initial concentration pair (ads. dose= 13 g/L).

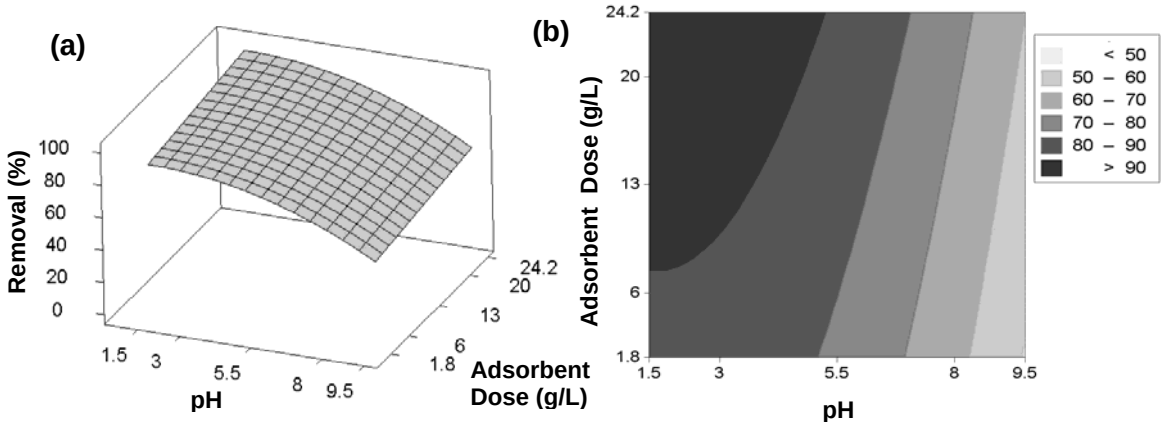

Figure 2. (a) Surface, **(b)** contour plot for pH-adsorbent dose pair (C_0= 55 mg/L).

The surface and contour plots showing the combined effect of pH and adsorbent dose is given in Figure 2. Although both plots exhibited enhanced Cr^{6+} removal at higher adsorbent doses, the improvement of removal percentage was not sufficiently high to justify excessive use of adsorbent and the related costs. When pH was held below pH 3, an adsorbent dose of 7 g/L was sufficient to ensure >90% Cr^{6+} removal 55 mg/L. For lower initial concentrations, even 2 g/L would be efficient at significantly acidic pH.

Initial concentration implied a considerable effect on the extent of Cr^{6+} removal. The combinational effect of initial concentration and adsorbent dose is shown in Figure 3. Accordingly, by utilization of 1.8g/L chitosan, at least 70% removal was attained from solutions as concentrated as 95 mg/L at pH 5.5. Higher extent of removal (>90%) was attained at relatively lower initial concentrations by using 15 g/L or more chitosan.

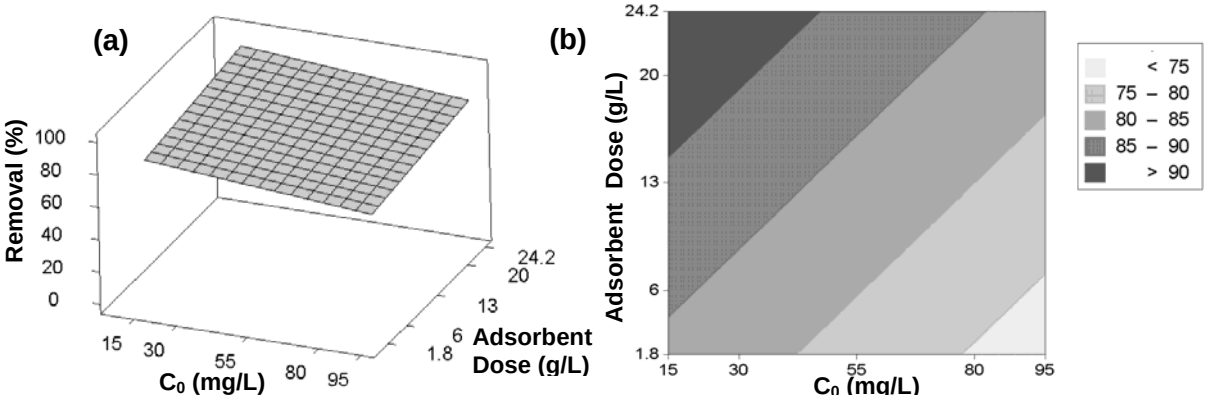

Figure 3. (a) Surface, **(b)** contour plot for initial concentration-adsorbent dose pair (pH=5.5).

The optimum set of process variables were predicted as pH 3, initial concentration of 30 mg/L and 24.2 g/L adsorbent dose by the model. At those conditions, the model predicted 100% Cr^{6+} removal. Experiments were conducted to check the accuracy of the optimum set of parameters and the resulting removal percentage was compared to the output of the model. Experimental results showed that only 89.2% removal could be attained at those conditions. Further experiments proved that the optimum adsorbent dose was 13 g/L, by which 92.9% Cr^{6+} removal was achieved.

3.3 Equilibrium Isotherms

The relationship between adsorbed metal concentration and concentration of the solution at equilibrium is described by isotherm models, of which Langmuir and Freundlich are the most widely referred equations. Whilst Langmuir isotherm model is representative of monolayer adsorption occurring on a homogeneous surface, Freundlich model is an empirical equation describing the adsorption on a heterogeneous surface. Both models are transformed into linear relationships so that the corresponding constants can be computed. Mathematical expressions for non-linear and linear forms of Freundlich model are given in eqn. 4 and 5.

$$q_e = K_F C_e^{1/n} \tag{4}$$

$$\ln q_e = \ln K_F + \frac{1}{n} \ln C_e \tag{5}$$

Here, q_e represents the mg amount of adsorbate adsorbed on unit amount of adsorbent and C_e is the equilibrium concentration of solution. K_F and n are constants for Freundlich isotherm (Dubey and Gopal, 2007).

Both Langmuir and Freundlich equations were involved in the interpretation of data obtained from experiments. Although the data fitted reasonably well to linearized forms of both models, the regression coefficient for Freundlich model was significantly higher, *i.e* 0.995.

The plot of ln q_e vs. ln C_e is shown in Figure 4. The Freundlich isotherm parameters K_F and n were calculated as 2.79 and 1.7, respectively.

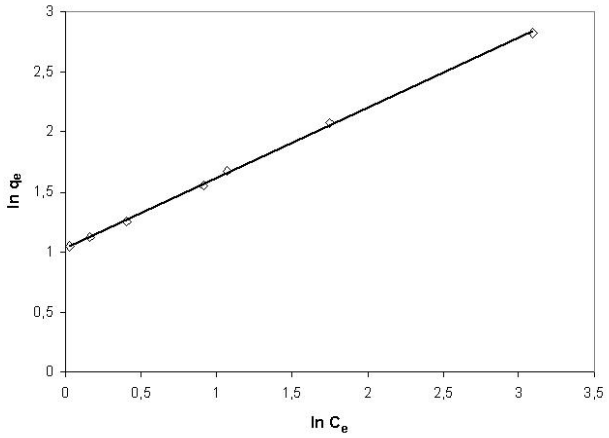

Figure 4. Linearized form for Freundlich isotherm model.

4 Conclusions

Chitosan has been found to be an effective adsorbent for Cr^{6+} removal from wastewater (Rojas et al., 2005), however several values have been reported for adsorption capacity and optimum process conditions. In this study, the optimum set of process parameters were determined as pH 3, initial concentration of 30 mg/L and 13 g/L adsorbent dose by surface responce methodology. The adsorption capacity of chitosan was calculated as 22.09 mg/g at these conditions. pH was determined to be the most effective parameter, followed with initial concentration and adsorbent dose, respectively.

Topic: Sustainable process-product development through green chemistry

Abstract

In the present work, the N3 dye was modified by substituting two of its protons by potassium or sodium cations. The performance and stability of DSC devices incorporating the new dyes were evaluated under light soaking (1000 $W \cdot m^{-2}$) at 50 ºC. Photocurrent measurements demonstrated that proton substitution by potassium cations rends the system more stable. Further characterization of the potassium-based devices was performed by electrochemical impedance spectroscopy, to investigate the charge transfer phenomena occurring at the different interfaces of the cells.

1. Introduction

Nowadays, a particular interest in the development of alternative energy sources arises, especially motivated not only by the need of reducing the dependency on fossil fuel resources, but also for providing the reduction of the CO_2 emissions. An attractive strategy in order to overcome the present energy problem is using renewable energy sources, such as the direct solar radiation, for producing clean energy. In this sense, the direct conversion of sunlight into electricity by means of photovoltaic systems makes an important contribution to this energy contend in an environmentally friendly way (Grätzel, 2001; Zweibel 2008). In conventional solar cells, the charge separation occurs at the interface of two materials of different conduction mechanisms, exploiting the photovoltaic effect (Grätzel, 2003). More recently, a new generation of cells emerged, the Dye-sensitized Solar Cells (DSC). DSCs are considered very promising since they use low cost, abundant and environmentally safe raw materials and they show relatively high-energy efficiency (Grätzel, 2001).

A DSC is made of a nanoparticulated titania film coated with an adsorbed dye monolayer. This thin film is applied on a glass substrate coated with a transparent conducting oxide (TCO) that collects the electrons. A back electrode consists of the same conducting glass coated with platinum. This serves as a catalyst for the redox reaction occurring in the electrolyte present in between the two electrodes (figure 1).

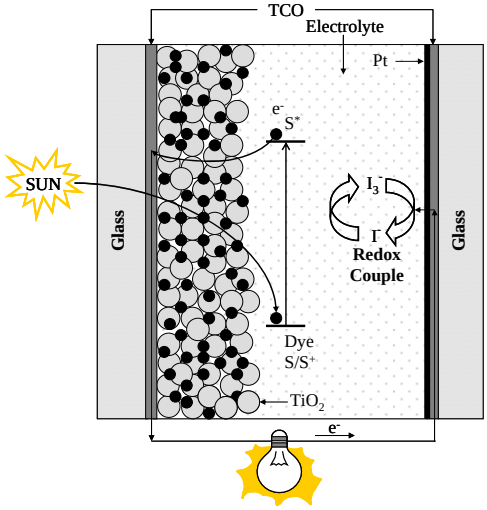

Figure 1 - Schematic representation of a dye-sensitized solar cell.

In DSCs, the dye is a crucial component to achieve high overall photoelectric conversion efficiency. Up to now, ruthenium complexes have been widely investigated

due to their advantageous spectral properties, photostability in the final device and high conversion efficiency (Amadelli *et al*., 1990). An example of these ruthenium polypyridine complexes with better performance as sensitizer is the cis-dithiocyanatobis(4,4'-dicarboxilic acid-2,2'-bipyridine)Ruthenium(II), commonly known as N3 (Nazeeruddin *et al*., 1993). Since the development of the N3 dye in 1993 (Nazeeruddin *et al*., 1993), its tetrabutylammonium (TBA) salt N719 has been used as the standard red dye because of its unmatched performances. Similarly to the N719 dye, new dyes were developed bearing in mind that the number of protons in the dye influences the open-circuit potential and the short circuit current of the DSC (Nazeeruddin *et al.*, 2003). In this work we modified the N3 dye by partially substituting its protons with different cations, namely sodium and potassium. The modified dyes where subsequently incorporated in final DSC devices, which were then submitted to accelerated thermal/light soaking aging tests for performance and stability evaluation. The cells were subjected to full sunlight irradiation at 50 ^{o}C for about 1000 h, during which time their photovoltaic parameters were periodically monitored. Electrochemical impedance spectroscopy (EIS) was used to investigate the charge transfer phenomena occurring at the different interfaces of the DSC. The charge-transfer resistance at the TCO layer, the charge-transfer resistance at the counter-electrode/electrolyte interface and the charge-transfer resistance at TiO_2/dye/electrolyte interface were obtained by fitting the EIS results to an appropriate equivalent electrical circuit (Fabregat-Santiago *et al.*, 2007).

2. Experimental section

N719 dye was synthesized as reported earlier (Nazeeruddin *et al.*, 1999). The dipotasium [$2K^{+}$(N3, $2H^{+}$)] and disodium [$2Na^{+}$(N3, $2H^{+}$)] dyes were prepared as follows. First N719 dye was dissolved in acetonitrile solvent and to this an excess amount of potassium triflate or sodium triflate in acetonitrile was added, and immediately the respective counter ion containing complex was precipitated, filtered and washed with acetonitrile and dried under vaccum.
Composition of electrolyte A: 0.1 M iodine, 0.5 M N-methylbenzimidazole in a mixture of BMII; PMITFSI; g-BL (2; 3 ;1) vol/vol.

Fabrication of DSC devices: The mesoscopic TiO_2 films used as photoanodes consisted of double layers of TiO_2 (7-μm thick transparent layer of 20 nm TiO_2 anatase nanoparticles and 5-μm thick scattering layer of 400 nm anatase TiO2 particles). The detailed method of TiO_2 film preparation and cell assembling was reported elsewhere (Kuang *et al.*, 2006).

Photovoltaic Measurements: All photovoltaic measurements were performed under a 450 W xenon light source able to provide 1000 W·m^{-2} sunlight equivalent irradiation (AM 1.5). *I - V* curves were obtained by applying an external bias to the cells and measuring the respective photocurrent response with a digital source meter (Keithley Instruments Inc.®, Model 2400). The incident photon-to-current conversion efficiency (IPCE) was recorded by a data-collecting system as a function of excitation wavelength. The incident light from a 300 W xenon lamp (ILC Technology, USA) was focused through a Gemini-180 double monochromator (Jobin Yvon., UK) onto the cell under test. No white light bias was applied and the dc photocurrents were in a domain where their response to light intensity was linear.

Electrochemical Impedance Measurements: Impedance experiments were carried out with a computer-controlled potentiostat (EG&G M273) equipped with a frequency response analyzer (EG&G M1025). The frequency range was 0.005 Hz-100 kHz and the magnitude of the modulation signal was 10 mV. All the measurements were performed at room temperature in the dark at -0.75 V bias. The EIS spectra were fitted to an appropriate electrical analogue by means of the Z View® software (v2.5b, Scribner Associates Inc.).

Stability Tests: Hermetically sealed cells were used to check the long-term stability under visible light soaking at 50 ^{o}C. The light soaking experiments employed a polymer film of 50-μm

thickness (Preservation Equipment Ltd, UK), eliminating UV light. Cells were exposed at open circuit to a Suntest CPS lamp (ATLAS GMBH, 100 mW·cm^{-2}, 50 ^{o}C) over a period of 1000 h. The cells were taken out at regular intervals to record the photocurrent-voltage curve.

3. Results and Discussion

Figure 2a) shows the photocurrent density-voltage curves under AM 1.5 simulated sunlight (1000 W·m^{-2}) for the DSCs prepared with [2K^{+}(N3, 2H^{+})], [2Na^{+}(N3, 2H^{+})] and N719 dyes in association with electrolyte A. The cells were labelled as device A, B and C, respectively.

Comparing the three systems under study, device C shows the best initial photovoltaic performance. In fact, it is already known by its unmatched performance. On the basis of cations' substitution in the N3 dye, the anchoring groups of the adsorbed sensitizer transfer most of its protons to the semiconductor surface, charging it positively. This change in the TiO_2 surface enhances the adsorption of the anionic ruthenium complexes and favours electron injection from the excited state of the dye into the conduction band of the semiconductor, resulting in higher photocurrents. Nevertheless, this positive shift of the Fermi level induced by surface protonation leads to a low open-circuit potential. In fact, if the sensitizer has no protons, it is expected to obtain high open-circuit potential and low photocurrents, and the other way round if sensitizer is fully protonated. So, an optimal degree of protonation of the sensitizer should be considered to reach maximum overall conversion efficiency (Nazeeruddin et al., 2003). In this study we observed that the sodium-based system (device B) presents higher values of short-circuit current, J_{sc}, and open-circuit voltage, V_{oc}, than cells with the potassium based system (device A). However, the latter system has higher overall power conversion efficiency, η, due to a higher value of the fill factor, *FF.* This fact is explained by a reduction in the series resistance of the cell with potassium salt dye.

In Figure 2b) the incident photon-to-current conversion efficiency (*IPCE*) for devices A, B and C can be compared. The *IPCE* is plotted as a function of the excitation wavelength. In line with the better photovoltaic performance, device C shows the highest *IPCE*: maximum of about 67 % at 530 nm. At the same wavelength, device A reaches a maximum of 63 %, while device B reaches approximately 54 %.

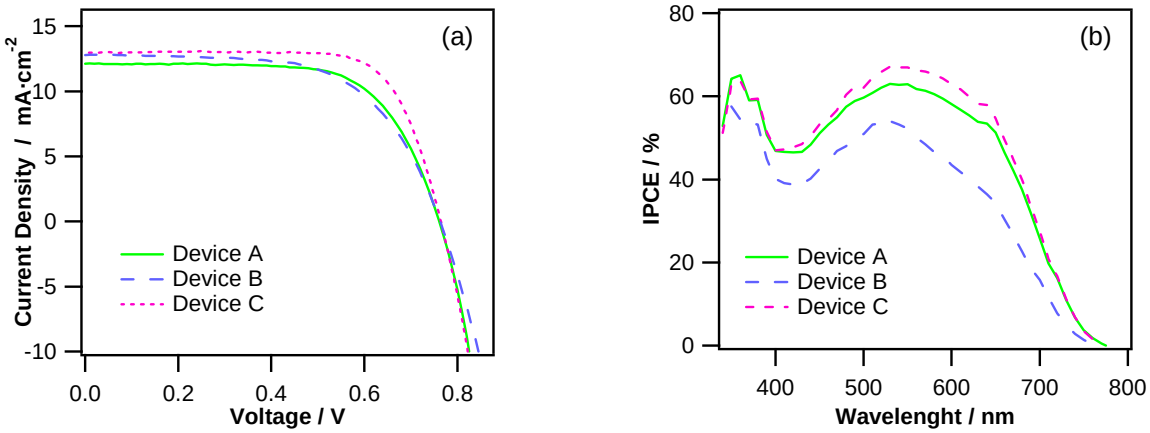

Figure 2 - a) Photocurrent intensity-voltage characteristics for devices A, B and C, measured at 1 sun (1000 W·m^{-2}), AM 1.5 global sunlight illumination. b) Photocurrent action spectra of the same devices.

Besides efficiency, the long-term stability is also a key issue regarding the industrial development and commercialization of DSCs. Thus, an intimate relation between photovoltaic performances and stability should be achieved. The evolution of the photovoltaic performances throughout the aging process of the three systems under study is presented in Figure 3. Device

A reveals a very good stability when compared with the two other systems. Actually, this device kept close to 90 % of its initial performance after 1000 h of light soaking at 50 ºC. In contrast, devices B and C showed a drop in efficiency of about 23 % and 25 %, respectively. The higher stability of device A is mainly due to increase in the photocurrent (6 %) during the first week of aging and latter it was maintained at the same level for the rest of the aging period. Additionally, this system shows a quite stable evolution of the *FF* values, indicating constancy in series resistance during the aging process. Despite its high photovoltaic performance as a fresh cell, the N719 system was unstable, exhibiting a marked decrease in J_{sc} and V_{oc} soon after the first week. This may be due to desorption of dye from the TiO_2 surface. Moreover, the sodium salt containing device B doesn't rend the system very stable, as suggested by the strong oscillation in all photovoltaic parameters of device B.

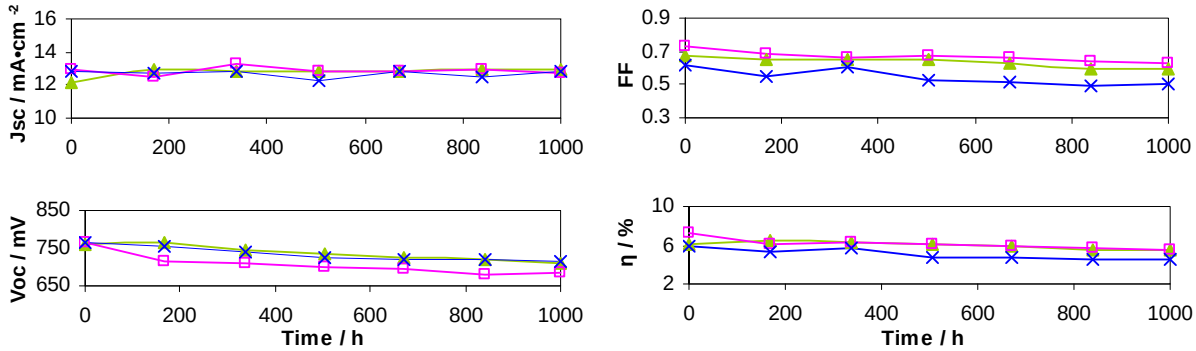

Figure 3 - Evolution of photovoltaic parameters for device A (▲), device B (x) and device C (□). The cells were kept under one sun visible-light soaking at 50 ºC for approximately 1000 h.

Bearing in mind the promising results in terms of performance and long-term stability of potassium-based DSC, a deeper characterization of the system was performed. In this sense, the effect of the aging process in the overall performance of device A was analysed by means of electrochemical impedance spectroscopy. This technique allows us to determine the charge-transfer resistances at the platinum counter-electrode and at the TiO_2/dye/electrolyte interface, as well as to determine the Nernstian diffusion of I^-/I_3^- ions within the electrolyte (Fabregat-Santiago et al., 2007). The Bode and Nyquist (*Z''*-imaginary part of impedance vs. *Z'*-real part of impedance) plots for the potassium system, before and after the aging process, are shown in Figure 4.

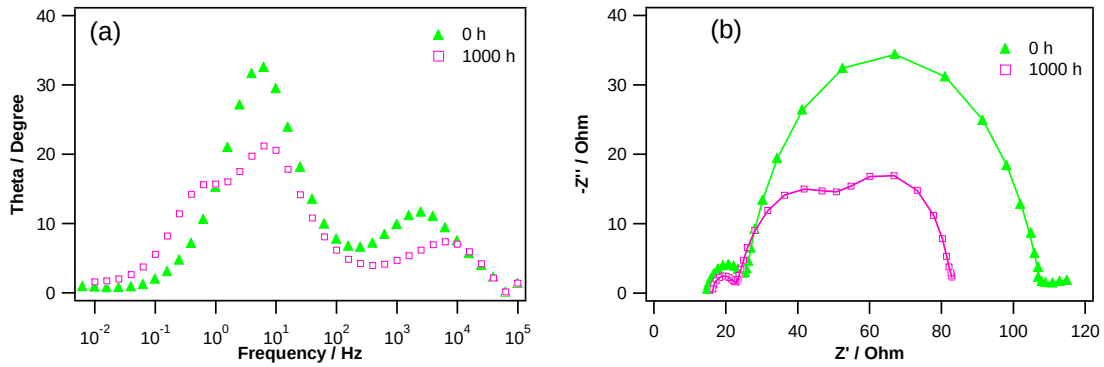

Figure 4 - Bode (a) and Nyquist (b) diagrams obtained for device A before and after 1000 h under thermal/light soaking stress. In the Nyquist diagram, symbols correspond to the impedance data obtained experimentally in the dark under -0.75 V bias, while solid lines represent the fittings (Wang et al., 2006).

Several physical models have been developed in an effort to understand all the complex charge-transfer processes that take place in DSCs (Wang et al., 2006; Bisquert et al., 2000; Adachi et al., 2006). Actually, the electron transport and charge recombination in nanocrystalline TiO_2 films have been widely studied by Bisquert et al. (Bisquert et al., 2000), who suggested an infinite transmission line model to describe the charge-transfer phenomena occurring at the TiO_2/electrolyte. Based on this model, the charge transfer resistance related to recombination of electron at the TiO_2/electrolyte interface (R_k) and the electron transport resistance (R_w) can be extracted as shown in Table 1 (Wang et al., 2006). Also the information about charge transfer at the counter electrode/electrolyte and the diffusion of iodide and triiodide within the electrolyte can also be obtained by using this model (Wang et al., 2006). Besides the determination of R_k and R_w, the effective rate constant for recombination (k_{eff}), the effective electron diffusion length ($L_e = d\sqrt{R_k/R_w}$ where d is the TiO_2 film thickness) and the effective diffusion coefficient of electrons in the TiO_2 semiconductor (D_{eff}) were also calculated.

Table 1. Parameters of device A determined by EIS, according to the procedure developed by Adachi et al (Adachi et al., 2006).

Exposure time / h	R_k / Ω	L_e / μm	k_{eff} / s^{-1}	D_{eff} / $cm^2 \cdot s^{-1}$
0	66.1	14.1	2.5	1.5×10^{-5}
1000	32.3	22.2	4.0	5.8×10^{-5}

Table 1 shows that L_e is much higher than unity in both fresh and aged cells, which suggests that the recombination resistance of electrons is much larger than the diffusion resistance in the TiO_2 layer, as expected. The increased J_{sc} for the aged sample can be attributed to the longer electron diffusion length compared to the fresh sample. As shown in Fig. 4a), the middle frequency peak position of the aged sample was slightly shifted to higher frequency, revealing a decrease in the electron lifetime, which is in line with k_{eff} in Table 1. The decrease of electron lifetime explains the drop of V_{oc} observed in aged devices. The decreased electron lifetime is mainly ascribed to a major decrease in R_k (in Table 1) for the aged sample compared to the fresh one. This means that electrons recombine more easily with the electrolyte upon aging. The same conclusions can be drawn from the significant decrease of the intermediate semicircle in Figure 4(b), which corresponds to a lower value of the charge-transfer resistance (R_k) at this interface. The increased electron diffusion coefficient was probably due to the positive shift of the conduction band energy level edge.

Finally, a decrease in the redox charge transfer resistance at the platinum counter electrode was observed upon aging. This explains the decrease of the left-hand side semicircle in the Nyquist diagram. This semicircle corresponds to the high-frequency peak in the Bode plot, which has moved towards larger values (meaning lower electron lifetimes and shorter redox reaction times). Additionally, an overlap between the photoelectrode impedance (middle semicircle) and that related to the Nernstian diffusion within the electrolyte (right-hand semicircle) can be noticed, probably due to a larger over potential for the I^-/I_3^- redox reaction on the platinum electrode for the aged sample, accompany with a fill factor problem (*FF* decreases from 0.67 to 0.59 upon aging).

4. Conclusion

Two N3-based dyes were synthesized bearing in mind that the number of protons in the sensitizer influences the open-circuit potential and the short circuit current of the DSC. Potassium and sodium cations were used to substitute two protons of the N3 dye and the resulting dyes were compared with the well-known N719 dye that contains two TBA (tetrabutylammonium) cations. Despite presenting the highest initial photovoltaic performance,

the N719 system was rather unstable, exhibiting a strong decrease in J_{sc} and V_{oc} upon aging, which might be due to the dye desorption. In addition, sodium substitution in place of TBA does not help to enhance the stability of devices, whereas substitution with potassium salt revealed better stability compared to the other two systems. In fact, this system kept close to 90% of its initial performance after 1000 h of light soaking at 50 ºC.

Abstract

Nanofiltration has been found to be an efficient treatment for the recovery of metals from aqueous streams. However, mechanisms involved in the removal of species by nanofiltration are still unclear. Thus, experimental studies are needed to know the features of nanofiltration membranes in removing specific substances. The nanofiltration of iron chelates by means of three commercial membranes, NF, NF270 and NF90 (from Dow-Filmtec), is presented. The effect of the pH on the chelates removal is investigated, finding that it affects both the chemistry of the solution and the membrane surface charge. Therefore, the retentions observed are strongly correlated to sieving but also to charge attraction/repulsion between the membrane and the iron chelates. All the membranes are able to be used at mid-acid pH (around 4.3) as their retentions are nearly 98% for all them. Also at slight basic pH of about 8.4, NF membrane still allows 95% iron retention whilst NF270 an NF90 show high iron retention of 99%. Finally, at the lowest tested pH (around 2.5), NF and NF270 membranes exhibit acceptable iron retention of 90% and 95%, respectively, however NF90 has found to be more sensitive to low pH and the retention observed with this membrane was only 53%.

1 Introduction

Membrane processes are being widely studied as useful technologies to recover contaminants from polluted waters. Nanofiltration is a promising membrane technology that allows the recovery of small size organic compounds as well as multivalent metal ions from aqueous streams. Nanofiltration mechanisms allowing the retention of such compounds are based on electrostatic interactions between the charged molecules (or ions) and sieving mechanisms due to the molecular weight cut-off of the membranes and the molecular weights of the targeted compounds (Van der Bruggen et al., 1999). Thus, it is of high importance to control both the chemistry of the solutions to be filtered as well as the membrane properties for correctly predicting the retention mechanisms involved in the separation process.

Nanofiltration membranes have been used for the recovery of a wide variety of organic compounds such as dyes (Van der Bruggen et al., 2001), herbicides (Plakas et al., 2006), aromatic compounds (Zhang et al., 2006), etc. In addition, nanofiltration has been used for the recovery of metal ions such as copper (Tanninen et al., 2006a), chromium (Frenzel et al., 2006), or cobalt (Choo et al., 2006) among many others.

Nowadays, chelating agents, such as ethylenediaminetetraacetic acid (EDTA), are broadly used in fertilizers, herbicides, detergents, as effective agents to remove metals from contaminated industrial containers, and even as promoters of the oxidation (Fenton-like processes) of biorefractory organic compounds when iron is also present in the reactive media. For the latter, the homogeneous catalytic pair (in this case, Fe-EDTA) leaves the oxidation reactor together with the partially-treated effluent, increasing the costs associated to the treatment and also adversely affecting the environment. Thus, the recovery of the complex Fe-EDTA is mandatory for solving the abovementioned problems.

In this study, nanofiltration is presented as a successful process for recovering Fe-EDTA chelates from synthetic wastewater. In addition, as Fe-EDTA complexes change in nature when the pH of the solutions is modified, the sieving and electrostatic effects involved in their retention have been investigated in connection with pH.

2 Materials and methods

Nanofiltration experiments were performed in a commercial batch filtration cell (Sterlitech Corporation, model HP4750) with a total capacity of 250 mL and an available filtration area of 14.6 cm^2. The cell is equipped with a controlled speed magnetic stirrer, (Selecta, model Agimatic REV-S). NF, NF90 and NF270 polymeric flat-sheet membranes were selected for this study. These membranes were manufactured and supplied (free of charge) by Dow Chemical Co. Iron (III) nitrate nonahydrate (Riedel-de Haën, purity 98%) and EDTA disodium salt dihydrate (Panreac, purity 99%) were used to prepare the solutions to be filtered. These solutions were always prepared by dissolving the stoichiometric amounts of Fe (III) and EDTA (1:1) in deionised water. The concentration of Fe(III) in the solutions was always 0.9 mM. Concentrated hydrochloric acid solution (Fluka, 37%) and sodium hydroxide (Sigma, purity 98%) were used to adjust the solutions to be filtered to the desired pH.

A typical filtration experiment started cutting the membrane sample in the adequate size. Then, the membrane was rinsed with deionised water and subsequently left overnight in deionised water. After this, the membrane was placed in the filtration cell and compacted with deionised water at 12 bar for one hour. The transmembrane pressure (TMP) was fixed thanks to the connexion of the cell with a nitrogen gas cylinder, a backpressure valve and a manometer. After the compaction step, 250 mL of solution to be filtered were added to the cell and a 10-mL sample was withdrawn for iron analysis, as explained below. After fixing the TMP at 6 bar and the magnetic stirrer at 300 rpm, the system was left to permeate until around 200 mL of initial solution had permeated. Thus a Volume Reduction Factor (initial volume/non-filtered volume) of 6 was achieved in the experiments. Permeate samples were periodically withdrawn for iron analysis to obtain the evolution of the iron retention percentage (%R) along the time. The %R was calculated as follows.

$$\%R = 100 \cdot \left(1 - \frac{C_P}{C_r}\right) \quad (1)$$

where C_P is the iron concentration in the permeate and C_r is the concentration in the retentate. The C_P and the initial iron concentration in the initial solution to be filtered were analysed by Atomic Absorption Spectrometry (Perkin Elmer, model 3100). As the filtration experiments were performed in batch mode, C_P changed along the time due to the continuous concentration of the original solution. This concentration was estimated from the mass balance supposing that no iron adsorption on the membrane took place. However, although the stirring does in principle decrease the concentration polarisation phenomenon and, in consequence, the extent of the iron adsorption impact, it has to be taken into account.

3 Results

3.1. Chemical speciation diagram

The formation of metallic chelates is strongly affected by the chemical conditions, such as pH, concentration of chelate and metal, ionic strength and so on. Thus, it is of great importance to know the exact species expected in the solutions to be filtered. Thus, the correlation between the filtration features and the chemical properties of the solutions could be more accurate. The chemical speciation diagram of a 0.9 mM Fe (III) – 0.9 mM EDTA solution, shown in Figure 1, was obtained with a freely available software (Puigdomènech, 2004) designed for this purpose.

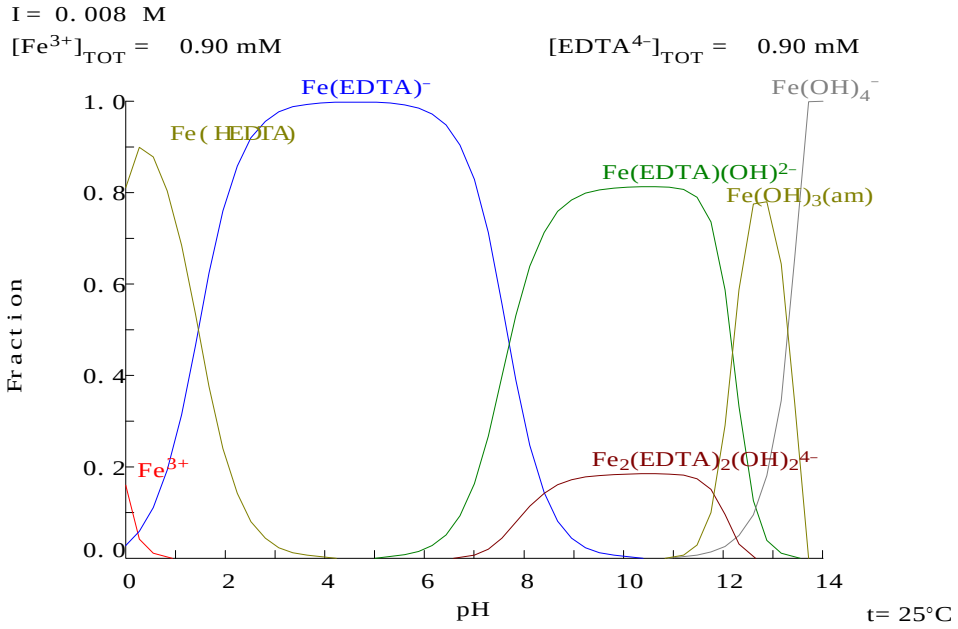

Figure 1. Chemical speciation diagram of the solution to be filtered.

As Figure 1 shows, the pH has a significant effect on the speciation of iron, concretely on the charge of the iron chelates formed. As the pH of the solution increases up to around 5, the fraction of Fe(HEDTA) and free Fe(III) decreases and that of $Fe(EDTA)^-$ increases until 100% of this species is achieved. Beyond this pH, the fraction of $Fe(EDTA)^-$ starts to decrease and $Fe(EDTA)OH^{2-}$ and $Fe_2(EDTA)_2(OH)_2^{4-}$ increase. The latter species is a clear example of the importance of the pH on the properties of the solution. This species has a higher molecular weight and presents a higher negative charge, which can affect the iron retentions obtained by nanofiltration. At pH 11, iron precipitate appears, indicating that chelation no longer occurs.

3.2. Filtration results

In this section, the iron retentions obtained with the three nanofiltration membranes are presented. The TMP was fixed at 6 bar for all the experiments and every membrane was tested at three different pH in order to test the effects of the speciation of the Fe-EDTA chelates on the iron retention efficiency.

Figure 2 shows the iron retention obtained with the NF membrane at several pH. NF membrane has the isoelectric point (iep) at around pH 5.1 (Tanninen et al., 2006b). Thus, at a pH lower than 5.1, the membrane surface is positively charged whilst at pH higher than the iep, the membrane is negatively charged. Thus, at pH 2.5 and 4.2, the membrane is positively charged. Figure 1 shows that the species present at these pH are negatively charged. Thus, the retention of the chelates at these pH is probably due to sieving effects. However, at pH 2.5, the retention is lower than at pH 4.2 because, at this pH, the membrane has a lower charge density than at higher pH, causing higher attraction, therefore decreasing

the iron retention. At pH 8.2, where both the membrane and the chelates exhibit negative charges, the retention may be due to both sieving effects and repulsive forces.

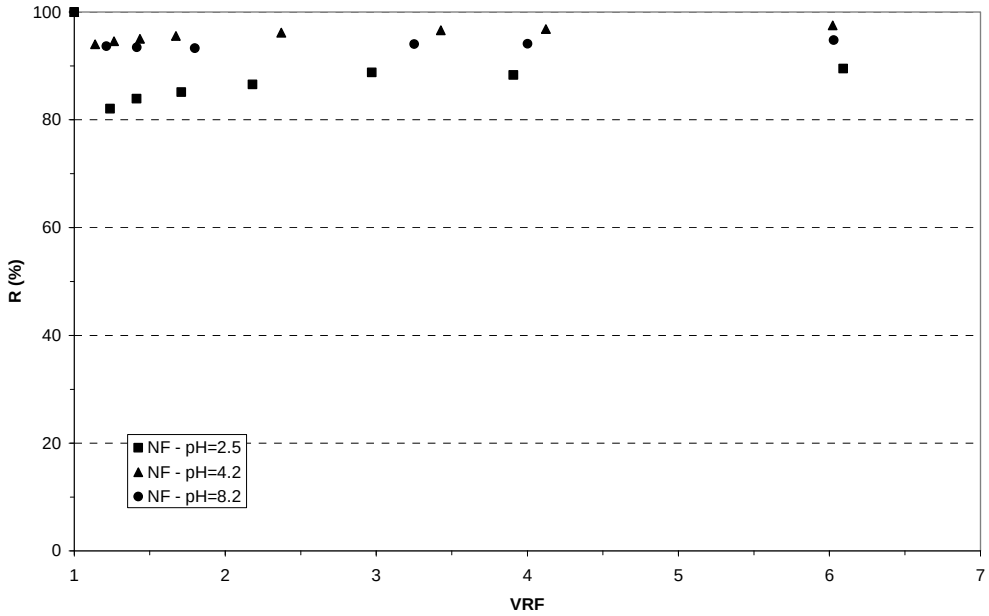

Figure 2. Effect of the pH on the iron retention by NF membrane.

Similarly to the NF membrane, iron retentions obtained with NF270 membrane are strongly correlated with the solution pH because it significantly affects the membrane charge as well as the iron chelate speciation. NF270 membrane has an iep of around 3.3 (Tanninen et al., 2006b). Figure 3 shows the effect of the pH on the iron retention when filtering with NF270 membrane.

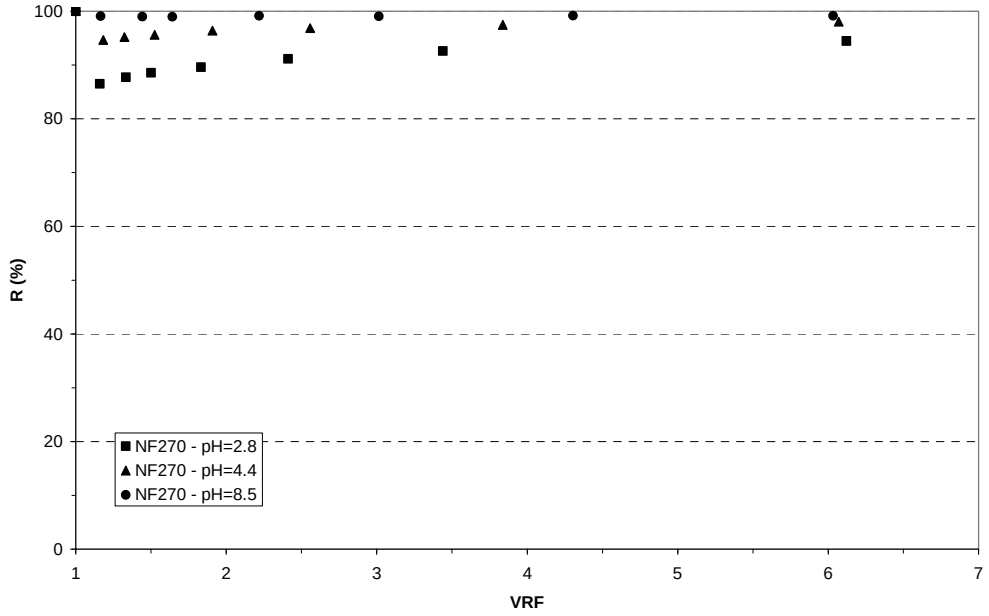

Figure 3. Effect of the pH on the iron retention by the NF270 membrane.

As it can be seen in Figure 3, at pH 2.8, the lowest retention is achieved. This result may be attributed to the low charge repulsion phenomena between the chelates and the membrane surface charge as the pH is very close to the membrane iep, decreasing the membrane charge. However, as with NF membrane, the retention in these conditions may be still due to sieving. At pH 4.4 and 8.5, where the membrane is negatively charged, the retentions

achieved are higher, being a little bit higher at pH 8.5. This behaviour could be assigned to the fact that at the highest pH, the membrane has a higher negative charge density, causing a slight increase on the iron retention due to the higher charge repulsion between the membrane and the chelated. In addition, at this pH, the presence of a small fraction of binuclear iron chelates, as shown in Figure 1, might also contribute to the increase on the iron retention.

Finally, the NF90 membrane was also tested for the recovery of iron chelates. NF90 membrane has an iep at pH 4.5 (Nghiem et al., 2005). As shown by Figure 4, at pH 2.4, the membrane also shows the lowest iron retention. However, in this case, the iron retention is much more lower (53% at a VRF around 6) than with NF and NF270 membranes. NF90 membrane exhibits higher positive charge at pH 2.4 than NF270 does (Nghiem et al., 2005). Thus, due to a higher attraction between the membrane and the positively-charged chelates occurring at pH 2.4 (see Figure 1), NF90 retention is lower than when for the other membranes. In addition, as with NF and NF270, at the lowest tested pH, the iron retentions significantly increased as the VRF did. Therefore, the iron retention increased from 27% to 53% when the VRF passed from 1.1 to 6.1. This trend may indicate that some adsorption phenomena are actually taking place and, in consequence, contributing to the iron retention. At pH 4.3 and 8.4, the retentions are higher than at pH 2.4 and comparable to those obtained with NF and NF270 membranes. A small difference between the iron retentions at pH 4.3 and 8.4 can be observed in Figure 4. At pH 4.3 the iron retention is 98% whilst at pH 8.4 is 99%. This could be a result of the almost no charge of the membrane at pH 4.3, because of the pH vicinity to the membrane iep (pH 4.5), thus decreasing the repulsions membrane-negative chelate, and consequently lowering the iron retention.

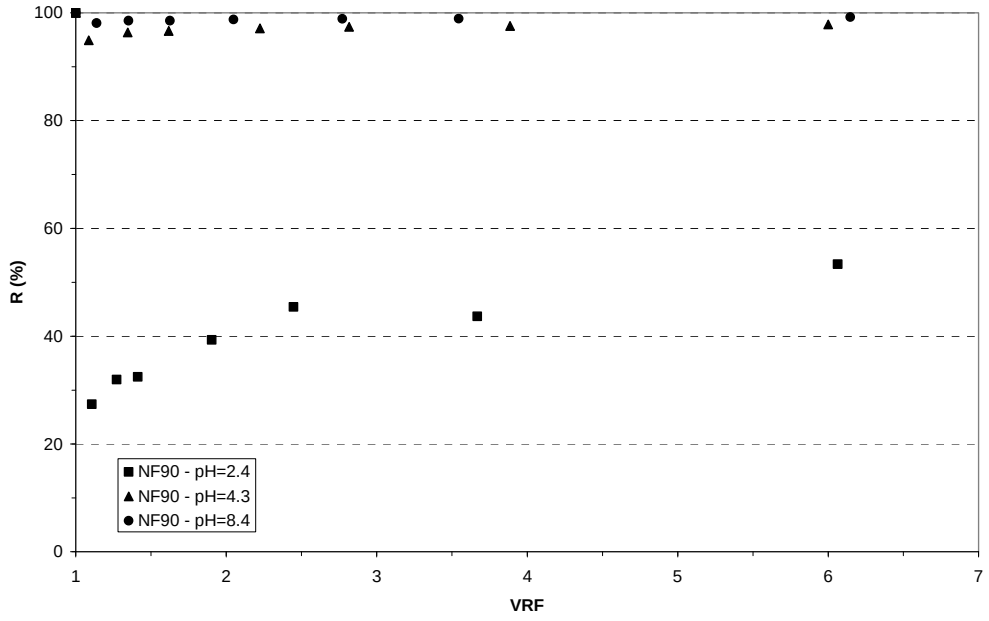

Figure 4. Effect of the pH on the iron retention by the NF90 membrane.

4 Conclusions

The removal of iron chelates by using nanofiltration membranes can be successfully achieved. However, the removal efficiency is strongly related to the chemistry of the solutions to be filtered and to the membrane properties. Particularly, the pH is found to be a crucial variable on the retention mechanism as it affects both the membrane charge (and charge density) as well as the speciation of the iron chelates. In general, the lowest retentions are obtained at the lowest tested pH (around 2.5), where all the membranes are positively charged and the chelates are negatively charged. This favours the attraction between the

charged species and the membrane surface, lowering the retention and also increasing the adsorption of chelated species onto the membrane. The iron retentions of NF, NF270 and NF90 at the lowest pH and at a VRF of around 6 have been found to be 90%, 95% and 53%, respectively. At the middle tested pH (around 4.3), the iron retentions at a VRF of about 6 were 98% for all the tested membranes. At the highest tested pH (around 8.4), the iron retentions at a VRF of around 6 were 95% for NF and 99% for both NF270 and NF90.

Sorption Isotherms of organic-inorganic hybrids

Vânia Dias, Dmitry Evtyugin, Inês Portugal*
Chemistry Department and CICECO - University of Aveiro, Campus de Santiago,
3810-193 Aveiro, Portugal

Keywords: Cellulose/Silica hybrids, O/I hybrids, Water Sorption, Isotherms
Topic: Sustainable process-product development through green chemistry.

Abstract

Water-vapour sorption of cellulose/silica hybrids was studied at different temperatures in the range 20 - 40 ºC using a static gravimetric method. Several isotherm models were tested to fit the multilayer type II isotherms obtained for these new hybrids. Best results were obtained with the BET equation for water activity ≤ 0.45 and the GAB equation for water activity ≤ 0.9. GAB model parameters were used to determine the difference between molar sorption enthalpies of the monolayer and the multilayer, ΔH_c = 18 kJ/mol, and the difference between molar sorption enthalpies of the bulk liquid and the multilayer, ΔH_k = -11 kJ/mol.

1 Introduction

Organic–inorganic hybrids (OIHs) are promising composite materials compiling in a synergetic way the properties of the starting components depending on the synthesis mode. Cellulose/Silica hybrids (CSHs) are an example of such materials (Sequeira *et al*. 2007) fitting well in the concept of green chemistry.

Cellulose is the most abundant biodegradable, recyclable and renewable natural polymer. The incorporation of silica in cellulose at the nanometer scale was accomplished by a mild sol–gel process, involving hydrolysis and polycondensation of tetraethoxysilane (TEOS) used as silica precursor. The reactions were performed at room temperature, using solid acid catalysts and benign solvents such as water and alcohol (co-solvent). The advantage of this sol–gel process is that silica particles are generated *in situ* and evenly dispersed in the polymeric host matrix (i.e. cellulose), bounding to the polymer through hydrogen or covalent bonds thus forming a three-dimensional network with -O-Si-O-Si- linkages on the cellulose surface (Sequeira *et al*. 2007).

The combination of nanoscale inorganic moieties with organic polymers, such as cellulose, has high potential for future applications. When compared to the starting materials these new OIHs exhibit improved thermal and mechanical stability, excellent heat and acoustic insulation properties, and improved dimensional stability to humidification (Sequeira *et al.* 2008). Altogether these properties render these materials suitable for insulation or packaging purposes.

The efficient processing and storage of cellulose/silica hybrids and the appropriate modeling and optimization of the drying process require the knowledge of moisture sorption isotherms at different temperatures. These isotherms describe the equilibrium relationship between moisture content and water activity at constant temperatures and pressures.

The most common procedures for obtaining water sorption isotherms are the gravimetric and the hygrometric methods. In the gravimetric method the air temperature and water activity are kept constant until the moisture content of the sample attains a constant equilibrium value. This technique involves the use of

* Corresponding author. Tel + 351-234 370 708 . E-mail:inesport@ua.pt

saturated salt or sulphuric acid solutions to maintain a constant relative humidity. The air may be circulated at constant flow (dynamic methods) or stagnant (static methods). In the hygrometric method the material's moisture content is kept constant until the surrounding air attains a constant equilibrium value, then the air-water activity is measured via hygrometer or manometer (Mujumdar *et al*. 2006).

The IUPAC classification of gas-solid adsorption isotherms (Fig. 1), based on the work of Brunauer *et al.* (1940), includes among others:

- Type I isotherms are typical of microporous solids and chemisorption;
- Type II isotherms are typical of finely divided non-porous solids and hydrophilic polymers such as natural fibers;
- Type III isotherms are typical of vapor adsorption i.e. water vapor on hydrophobic materials; for example rubbers, plastics and synthetic fibers (Mujumdar *et al*. 2006).

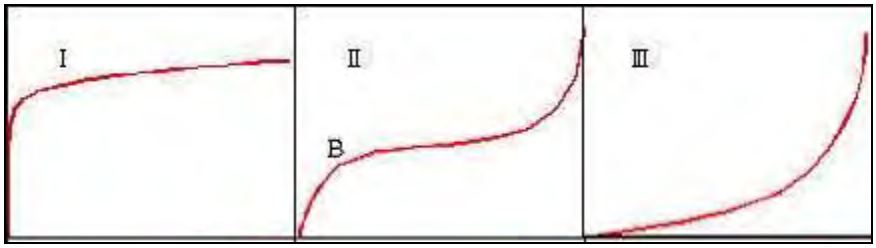

Figure 1- IUPAC classification of adsorption isotherms (Brunauer, 1940).

Several mathematical models exist to describe adsorption isotherms. Available models suitable to describe moisture sorption isotherms can be divided into several categories: kinetic models based on monolayer adsorption (BET model) or multilayer adsorption and condensed film (GAB model), semi-empirical models (Henderson and Halsey models) and empirical models (Smith and Oswin models).

The Brunauer-Emmet-Teller (BET) model represents a fundamental milestone in the interpretation of monolayer sorption isotherms, particularly types II and III (Krupinska *et al.* 2007) but this model is generally restricted to values of water activity (a_w) below 0.45 because of the assumptions used in the derivation of the equation.

The BET model is represented by equation (1)

$$Xeq = \frac{MCa_w}{(1-a_w)(1-a_w+Ca_w)} \quad \textbf{(1)}$$

where, where Xeq is the equilibrium moisture content expressed as grams of sorbate per gram of adsorbant, a_w is the water activity, M and C are the model's constants. Theoretically, M (g water/g dry solids) is the monolayer moisture content and C is a constant related to the heat of adsorption.

The Guggenheim-Anderson-deBoer (GAB) model represents an extension of the BET model valid for $a_w \leq 0.9$. In this model, represented by equation (2), a third constant K is introduced to describe the modified properties of the sorbate in the multilayer region in relation to the sorbate in the monolayer and in the bulk liquid (Timmermann, 2003).

$$Xeq = \frac{MCKa_w}{(1-Ka_w)(1-Ka_w+CKa_w)} \quad \textbf{(2)}$$

where Xeq, a_w and M are as above mentioned, C is a constant related to the first layer heat of sorption and K is a factor related to the multilayer adsorption heat. The influence of temperature on GAB parameters C and K can be expressed by Arrhenius type equations (3) and (4)

$$C = C_0 \exp\left(\frac{\Delta H_c}{RT}\right), \quad \text{with} \quad \Delta H_c = h_m - h_n \tag{3}$$

$$K = k_0 \exp\left(\frac{\Delta H_k}{RT}\right), \quad \text{with} \quad \Delta H_k = h_i - h_n \tag{4}$$

where C_0 and k_0 are entropic accommodation factors; ΔH_c and ΔH_k are functions of the water heat of sorption; h_m, h_n and h_i are sorption enthalpies (J/mol) of the monolayer, the multilayer and the bulk liquid (heat of condensation of water vapour), respectively; R (J/mol K) is the ideal gas constant and T (K) is the absolute temperature (Telis *et al.* 2000).

The monolayer moisture content, determined with the BET model (for $a_w \leq 0.4$) or GAB model (for $a_w \leq 0.9$), is related to the solid's surface area according to equation (5)

$$S = M \frac{N_A A_m}{M_w} \tag{5}$$

where S is the solid surface area (m^2/g dry solids), M is the monolayer moisture content (g water/g dry solids), M_w is the molecular weight of water (18 g/mol), N_A is Avogadro's number (6×10^{23} molecules/mol) and A_m is the projected area of a water molecule (1.06×10^{19} m^2) (Togrul *et al.* 2006).

The objectives of this study were to obtain the sorption isotherms of cellulose/silica hybrids (CSHs) based on *Eucalyptus globulus* kraft pulp, to select a suitable isotherm model and to determine the characteristic thermodynamic parameters.

2 Experimental procedure

Sorption isotherms of CSHs containing 34% of silica were determined by a static-gravimetric method at different temperatures, in the range 15 - 40 ºC, using an experimental setup similar to that presented in Fig. 2.

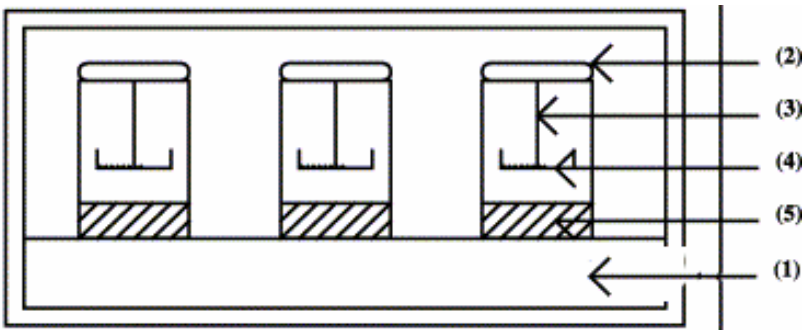

Figure 2: Experimental setup: (1) thermostatic bath, (2) closed flasks, (3) sample holder, (4) CHSs samples, (5) saturated salt solution (adapted from Lahsasni *et al.* 2003).

Saturated aqueous salt solutions of KOH, CH_3COOK, $MgCl_2.6H_2O$, K_2CO_3, $Mg(NO_3)_2$, KI, $(NH_4)_2SO_4$ and KNO_3 were used to control the atmosphere's moisture content (RH, %) in the range 7% to 95% (Greenspan *et al*. 1977; WebbTech). Excess salt was maintained in each solution.

CSHs samples (≈ 1 g) were oven-dried overnight at 105 ºC, dehydrated over P_2O_5 during 8 days, weighted and placed in flasks containing the saturated salt solutions. The flasks were closed and placed in a shaking water bath (Julabo SW23) at controlled temperature (± 1 ºC) and weighted regularly (Mettler toledo, sensitivity ± 0.0001g) until

reaching a constant weight (≈ 15 days). Experiments were stopped when the difference between two successive weightings in different days was less than 0.001g.

3 Results and discussion

The experimental results for CHSs water sorption isotherms in the range of 20-40 ºC are presented in Fig. 3. These results are consistent with type II isotherms (IUPAC classification) and clearly reveal that the amount of adsorbed water decreases with temperature, indicating that CHSs becomes less hygroscopic at higher temperatures.

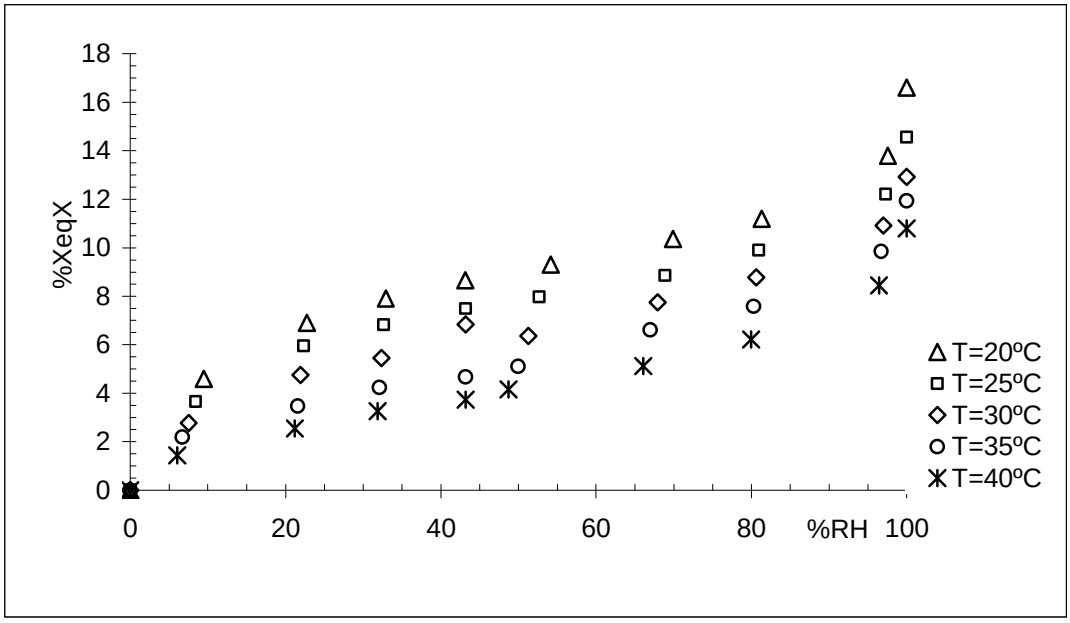

Figure 3: Experimental data (equilibrium water content –Xeq, *versus* relative humidity – %RH) for celulose/silica hibrids at temperatures in the range of 20 - 40 ºC.

In the region of low and intermediate water activities, also known as multilayer sorption region, the moisture content increases linearly with a_w, whereas at high water activity levels, designated as capillary condensation region, the water content rapidly increases with a_w. A possbile explanation for the behaviour at low water activities is the occurrence of physical adsorption of water on strongly active sites such as surface –OH groups of cellulose/silica hybrids.

Several sorption isotherm equations (GAB, BET, Oswin, Halsey) were tested to model the experimental data for CSHs water sorption at 25ºC, using nonlinear regression analysis. Goodness of fit was evaluated by the mean relative percentage deviation, P, defined by equation (6).

$$P = \frac{100}{N}\sum_{i=1}^{N}\frac{\left|Xeq_{\exp-i} - Xeq_{calc-i}\right|}{Xeq_{\exp-i}} \qquad \textbf{(6)}$$

The GAB model was found to be the most suitable for describing the sorption data but the BET model (for $a_w < 0.45$) was also selected for further analysis for it is recommend by IUPAC for solids characterization (Timmermann, 2003). The experimental results and the GAB and BET sorption isotherms at 25ºC are shown in Fig. 4.

Throughout the entire range of water activity and temperature the fitness of the GAB model was better than the BET model. Parameters for both models (C, M, K) are presented in Table 1 together with the mean relative percentage deviation (P) and specific surface area (S).

The value of the monolayer moisture content (M) obtained by GAB and BET models is an important parameter for it is a measure of the sorption capacity of a solid material

and an indicator of available polar sites for water vapour binding (Mihoubi *et al.* 2006). M values of CSHs decrease with increasing temperature which indicates that the sorption capacity is lower at higher temperatures. As temperatures rises so does the kinetic energy of water vapour molecules surrounding the CHSs samples and thus the monolayer moisture content is reduced (Mihoubi *et al.* 2006). The value of M is sistemathically lower for the BET model as stated by Timmermann (2003).

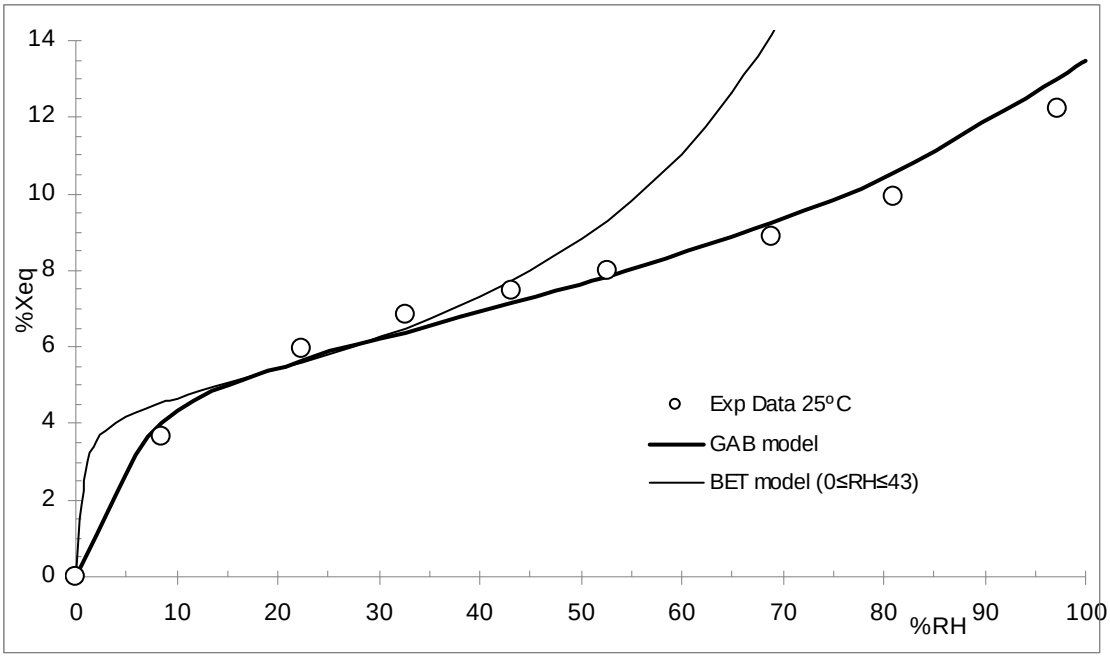

Figure 4: Experimental data (equilibrium water content –Xeq, *versus* relative humidity – %RH), GAB and BET model fitting for celulose/silica hibrids at 25ºC.

Table 1: Estimated GAB and BET model parameters, mean relative percentage deviation (P) and estimated surface area (S) at different temperatures.

Model	parameters	Temperature (ºC)				
		20	25	30	35	40
GAB	M (g water/g dry solids)	0.0665	0.0577	0.0467	0.0353	0.0267
	C	42.5	38.2	35.3	31.5	26.0
	K	0.572	0.581	0.617	0.694	0.742
	P(%)	5.2	5.3	6.2	2.6	4.3
	S (m^2/g dry solids)	235	204	165	125	94.3
BET	C	224	146	53.1	128	56.7
	M (g water/g dry solids)	0.0511	0.0444	0.0391	0.0283	0.0219
	P(%)	6.3	7.6	5.9	7.0	5.8
	S (m^2/g dry solids)	180	157	138	99.9	77.3

The values of the GAB parameter K, a correction factor related to properties of the multilayer adsorption, are lower than 1 (Table 1). This suggests that water adsorption on CSHs involves multilayers. Furthermore, the fact that K increases with temperature is related to the negative effect of temperature on adsorption. As K aproaches unity the GAB model aproaches the BET model that accounts only for monolayer adsorption.

The values for total surface area (S) obtained with the GAB model and with the BET model are quite different and the BET model underestimates S values (Timmermann, 2003). However, in both models the effect of temperature is consistent indicating that the total surface area available for hydrophilic bonding decreases with temperature.

The effect of temperature on the GAB model's parameters was analyzed using equations (3) and (4). The resulting thermodynamic parametes are shown in Table 2. The difference between molar sorption enthalpies of the monolayer and the multilayer, $\Delta H_{c,}$ is = 18 kJ/mol and ΔH_k, the difference between molar sorption enthalpies of the bulk liquid and the multilayer is -11 kJ/mol. The large positive value of $\Delta H_{c,}$ is due to the strong interaction of water vapour with the sorption sites of CSHs. The negative value of ΔH_k indicates an exothermic interaction of water vapour with CSHs and confirms the tendency to multilayer reduction when temperature rises as mentioned earlier (Togrul *et al*. 2006).

Table 2: Estimated GAB parameters.

Monolayer Parameters		Multilayer Parameters	
C_0	0.0277	k_0	42.7
ΔH_c (KJ/mol)	17.9	ΔH_k (J/mol)	-10.6

[1] DEQ – Departamento de Engenharia Química, Centro Tecnológico, UFRN, Campus Universitário, CEP: 59072-970, Natal/RN, Brasil.

Keywords: Solar evaporation, Produced water, Steam pressure, Salting effect, Boiling point

Topic: Advancing chemical and biological engineering fundamentals.

Abstract

Produced waters are a complex mixture of water, salts, oil, microorganisms and traces of heavy metals. Owing to this complexity, the conventional techniques used to treat these waters are onerous and a suitable final destination for them must also be found. It is desirable and beneficial to study new alternatives for the treatment and final disposal of these effluents. This study was to investigate the variation in solar evaporation of samples of potable water and produced water, in aluminum trays coated with commercial Teflon. The work was developed in the city of Natal, whose solar radiation is around 5000 W/m^{2}d. The trays used were made of commercial Teflon with a capacity of 2.8 L. The experiment consisted of placing 1 L of sample from each tray and exposing them to the sun for an equal period of time: from 10 to 14 h. Temperature was monitored using a mercury thermometer and the amount that evaporated from each tray was measured at the end. The results demonstrate that there were no significant temperature variations between the trays, which remained between 39°C and 40°C during the experiment. The average volumes evaporated in this interval were 400 mL for potable water and 403 mL for produced water. These results show that evaporation output varied between 34% and 40%, and it should be pointed out that the evaporation rates in this case are influenced by temperature, pressure, wind and solar radiation. The incident solar radiation peaks on the experimental days varied between 1061.30 and 844.40 W/m^2, corresponding to the highest and lowest output, respectively. This study highlights the importance of a more thorough knowledge of the solar evaporation process of produced water, given industry requirements of returning the water to the hydrologic cycle with the least environmental damage possible and collecting the salt for more adequate disposal.

1 Introduction

Water, considered the universal solvent, is undoubtedly one of the most important substances for maintaining life on Earth. Its presence for the survival of live beings and for the performance of human activities is indispensable.

In addition to acting as a solvent and raw material in industrial processes, water acts as an input in the heating or cooling of systems and is even a subproduct of a number of processes such as oil production. Regardless of its use, legislation, which is increasingly restrictive, requires that the effluents generated be treated and disposed of properly.

Understanding and predicting the behavior of aqueous systems is useful and necessary in every sense, be it optimizing its industrial use (minimizing waste), be it improving the

* Corresponding author. Tel + (55)3215-3757-(209). E-mail:josette@eq.ufrn.br

treatment systems of effluents and their final disposal or reuse (Bezerra, 2004).

Among the industrial operations performed with water, the evaporation processes stand out. In many industrial processes a highly saline effluent is produced and in these cases the water must be separated from the salts and solar evaporation may be a viable alternative to perform this operation, both for allowing the reuse of the salts and as a way to return the water to the environment.

Pure water boils at 100°C at atmospheric pressure and although the water on Earth is not pure, owing mainly to its power of solvency, this temperature may vary in real systems, depending on the elements that this mixture contains.

Water evaporation, however, begins at zero degrees. In the so-called triple point the three states of matter coexist (Van Ness, 1980). When temperature rises in an isobaric system, the evaporation rate also rises, reaching the boiling point at around 100°C. It is known that saline solutions raise the boiling point (bp) of water by reducing its water pressure. On the other hand, volatile organic compounds increase water vapor pressure and consequently its evaporation rate.

Produced waters are a complex mixture of water, salts, oil, microorganisms and traces of heavy metals (Azevedo, 1998). Due to this complexity these waters may have their boiling point moved up or down and this displacement is defined by their individual characteristics, which are quite inconstant, varying from one producing field to another and depending on the treatment used to extract the petroleum. According to Schulli (2003), evaporation towers have been used to desalinate produced water using electrical energy.

2. Objectives

The aim of the present study was to study the variation in solar evaporation of potable water (groundwater) and produced water (low organic concentration) samples at the same pressure, in aluminum trays coated with commercial Teflon.

3. Methodology

The work was carried out in the city of Natal, Northeast Brazil (5º 47’ 42” S 35º 12’ 32” W), whose mean solar radiation is around 5000 W/m^{2}d. The 2.8 L trays were made of commercial Teflon. The experiment consisted of placing 1L of each sample type in the corresponding tray and exposing them to the sun for an equal period of time: from 10 to 14 h. Temperature was monitored using a mercury thermometer and the amount that evaporated from each tray was measured at the end. Figure 1 shows the configuration of the experiment.

Figure 1: Teflon trays for sample evaporation

The conductivity and pH of the samples were measured. The results are shown in Table 1.

Table 1: Characteristics of the sample before the experiments (average values)

Parameters	Potable water	Produced water
pH	8.8	8.7
Conductivity (μS/cm)	357	3,500

4. Results and discussion

The results demonstrate that there were no significant temperature variations among the trays, which remained between 39°C and 40°C during the experiment. The average volumes evaporated in this interval were 400 mL for potable water and 403 mL for produced water, which was also not significant. The largest difference was for the tray with potable water, which evaporated 340 mL, whereas the tray with produced water evaporated 330 mL. These findings indicate that, for the samples with these characteristics, the effects tend to cancel each other out, in contrast to the results of conventional distillation tests, which point to a higher T_{bp} at 100°C, showing in this case, the effect of the salt.

It was found that the evaporation output varied between 34% and 40% and it should be pointed out that the evaporation rates in this case are influenced by temperature, pressure, wind and solar radiation. A comparison of solar radiation values showed that the largest outputs were obtained when the highest radiations occurred and the smallest outputs at the lowest radiations, which were 1061.30 and 884.40 W/m^2, respectively.

5. Conclusions

The study highlights the importance of a more thorough knowledge of the solar evaporation process of produced water, given industry requirements of returning the water to the hydrologic cycle with the least environmental damage possible and collecting the salt for more adequate disposal.

Topic: Sustainable process-product development through green chemistry. Environmental engineering & management

Abstract

The first wastewater treatment plant of an innovative biological treatment, named symbiotic depuration (Golftrat, 2007), was constructed at the Campus of Espinardo (University of Murcia), supported by the successful experience assays carried out in pilot scale (Llorens et al., 2004). The cited technology combines a natural and subterranean treatment with the generation of green areas over the surface of the plant. It is a promising technology, when comparing with conventional systems, due to the simple operational and maintenance procedures and the high depuration rates. The removal efficiency is up to 86 % for COD, 94 % for BOD, and 81 % for suspended solids, with an average nitrogen and phosphorus removal of 86 % and 84 %, respectively. Besides, an increasing in dissolved oxygen is obtained along the treatment with the consequent increase in nitrates concentration. With the final treatment in the wetland an important level of denitrification is achieved. The overall treatment plant provides an effluent with adequate quality for reuse as garden irrigation waters.

Introduction

Rapid population growth and industrial development have put extreme pressure on future demands for water. Additional human activities (household cleaning, industrial uses, hospitals, business, and schools) cause the deterioration of water resources. So, an adequate management and conservation of water resources is required.

There is a great quantity of conventional wastewater treatment systems, nevertheless they require high construction and operational costs. Nowadays, priority has been given to those technologies which have a minimum cost, with simple operational and maintenance procedures, and which guarantee efficiency and a high level of inertia when faced with large fluctuations in the flow and the effluent load to be treated, and which simplify sludge handling processes.

An innovative technology, named “symbiotic plant®” (Golftrat, 2008), was selected for this purpose. It is a clean and ecological technology, and has as its main characteristic the existence of two well-distinguished areas, the depuration area and the cultivation area. The water is applied by means of underground drippers to a gravel bed over which a green area is situated. So, the evaporation losses are minimal, the green areas can be used even during irrigation and direct contact of users of such areas with residual waters is prevented.

After carrying out diverse assays at pilot scale and verifying the suitability of the cited technology for treating the wastewater from the university installations and a nearby housing development (Lloréns et al., 2004), ESAMUR (Wastewater Treatment

* Corresponding author. Tel + 34 968 367515. E-mail: abelenpm@um.es

Organisation of Murcia) had provided the economic support to carry out the construction and the scientific study of “An Experimental Symbiotic Wastewater Treatment Plant” in the Campus of Espinardo (University of Murcia). This paper shows the results of the physico-chemical control of this pioneering plant, during the first year of operation, in order to demonstrate the success of this system to treat the wastewater generated at the University of Murcia and the possibility of applying this technology to the wastewater generated in small villages.

Materials and methods

Experimental wastewater treatment plant of the University of Murcia

The wastewater treatment plant, designed by Golftrat, S.L. for treating 500 m^3/d, is integrated by a physical treatment and the symbiotic treatment. A flowsheet of the plant can be shown in Figure 1.

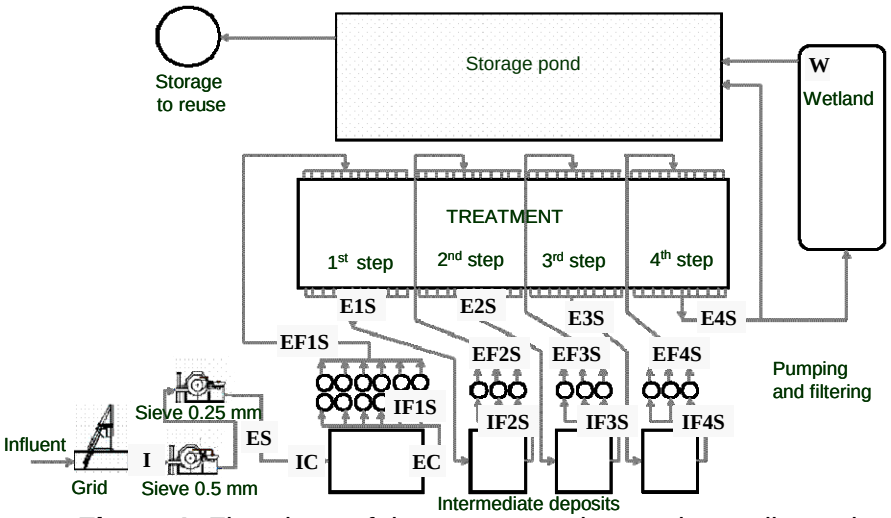

Figure 1. Flowsheet of the treatment plant and sampling points.

The wastewater is pretreated before entering the symbiotic plant. The pretreatment consists of two subsequent rotary sieves with 0.5 and 0.25 mm sieve openings, respectively, a clarifier (recentely installed in order to reduce the inlet solid content to filters) and a series of twelve 50 µm mesh ring filters.

Pretreated wastewater enters the biological treatment, which consist in four symbiotic stages placed in series. Each symbiotic stage consists of a depuration area, 120 cm thick of gravel bed, which is isolated from the ground by a waterproof layer. A network of subterranean drippers, placed directly on the gravel, is used to apply the wastewater. The cultivation area is situated over this area and is composed by approximately 30 cm of sandy substrate. Each stage provides a filtering surface of 205 m^2/stage.

Pretreated wastewater enters the first stage of the symbiotic plant through the drippers falling by gravity through the gravel bed until it reaches the bottom waterproof layer. The effluent is collected in a deposit and then filtered through a series of three 75 µm size mesh filters before being pumped to the next stage. The effluent from the fourth stage falls by gravity into an artificial wetland or a storage pond. Treated water is reused as irrigation water.

The clarifier, situated after the pretreatment, collects the small amounts of sludge generated by sloughed off biofilm from the surface of the gravel bed and the wash water from cleaning filters and drippers. Nine daily sludge purges of two minutes each one are made. The total volume purged is 1.35 m^3/d (≅ 4.5 kg/d) and the sludge purged is used for composting.

Sampling and methods

Physico-chemical analysis was made of samples collected from: influent (IS) and

effluent (ES) of the rotatory sieves, influent (IC) and effluent (EC) of the clarifier, influent (IFnS) and effluent (EFnS) of each filter battery and inlet (InS) and outlet (EnS) of each one of the four treatment stages (n = number of stage). Samples were also collected in the wetland (W) to asses the improvement in the water quality after this final treatment. Samples were analysed to follow-up several pollution parameters according to the treatment: total suspended solids (TSS), chemical oxygen demand (COD), biochemical oxygen demand (BOD_5), total Kjeldahl nitrogen (TKN), ammonia nitrogen ($N\text{-}NH_4^+$), nitrates, total phosphorus (TP) and phosphates. pH, conductivity and dissolved oxygen (DO) were also measured. All water samples were analysed in accordance with the Standard Methods for Examination of Water and Wastewater (APHA, 1995).

Results and discussion

In this section, box plot are used to evaluate the experimental results. The upper and lower box indicate 25th and 75th percentile, the whiskers are the 5th and 95th percentile, the symbols represent the outliers, the solid line is the median and the dashed line is the mean.

Characterization of wastewater

As can be seen in Figure 2, there is a great variation in the influent composition. The raw wastewater is comparable to a domestic wastewater with high strength (Metcalf&Eddy, 1995).

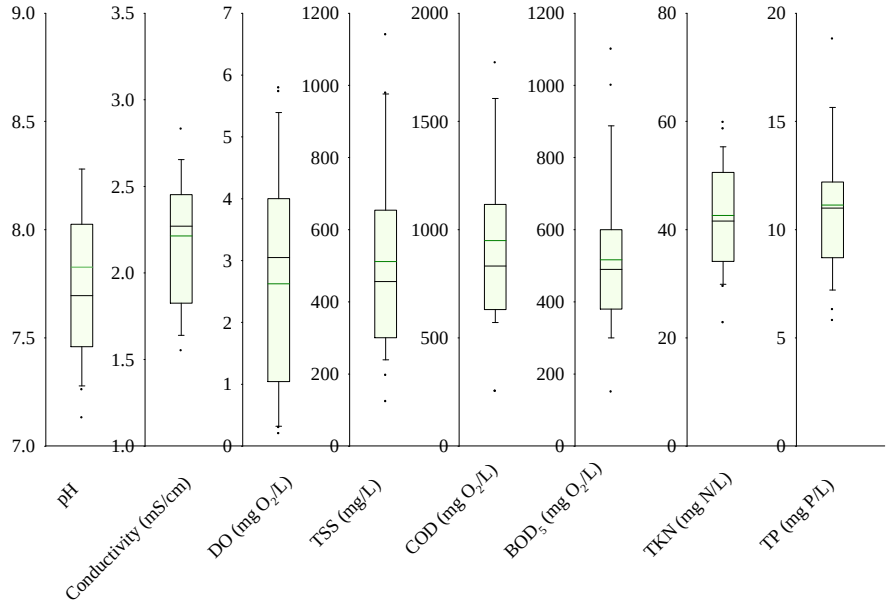

Figure 2. Influent composition.

Evolution of different parameters along the treatment

According to the obtained results, pH values fall well within the optimum range for the growth of the microorganisms for digesting organic matter (6.6-8.5). The conductivity remains almost constant along the depuration process and its value oscillate between 1.7 and 2.8 mS/cm.

The dissolved oxygen is one of the most important parameters in this system. As it can be seen (Figure 3.a.), an increase in the concentration of dissolved oxygen along the steps of the symbiotic plant was observed. The gravel bed remains unsaturated at all times, so the water which irrigate the gravel bed is always in contact with air, and so that depuration is carried out in aerobic conditions. The highest concentrations of dissolved oxygen are achieved within the wetland. The oxygen supply is via the air-water surface exchange and the photosynthesis of the phytoplankton and algal biofilms

attached to the surface of the emergent aquatic macrophytes present in the wetland.

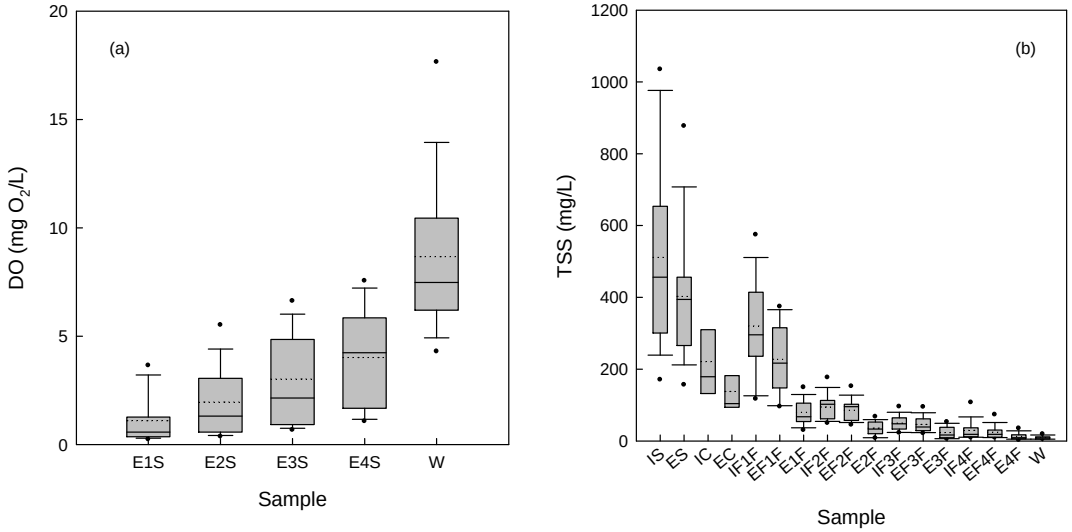

Figure 3. Box plot of the evolution in dissolved oxygen (a) and in total suspended solids (b) through the depuration process.

An important decrease in total suspended solids is achieve with the treatment (Figure 3b). The sieves, the clarifier, the filters and the symbiotic bed of the first stage give the major contribution to the removal of suspended solids. It is neccesary to point up that, after the pretreatment, symbiotic beds rather than filters accounts for the main contribution to TSS removals. The small amounts of sludge generated by sloughed off biofilm from the surface of the gravel beds, settle down rapidly in the deposits of treated wastewater of each stage and they were carried to the clarifier without pass to the filters. Filters of the three last stages do not provide a significant decrease in this parameter.

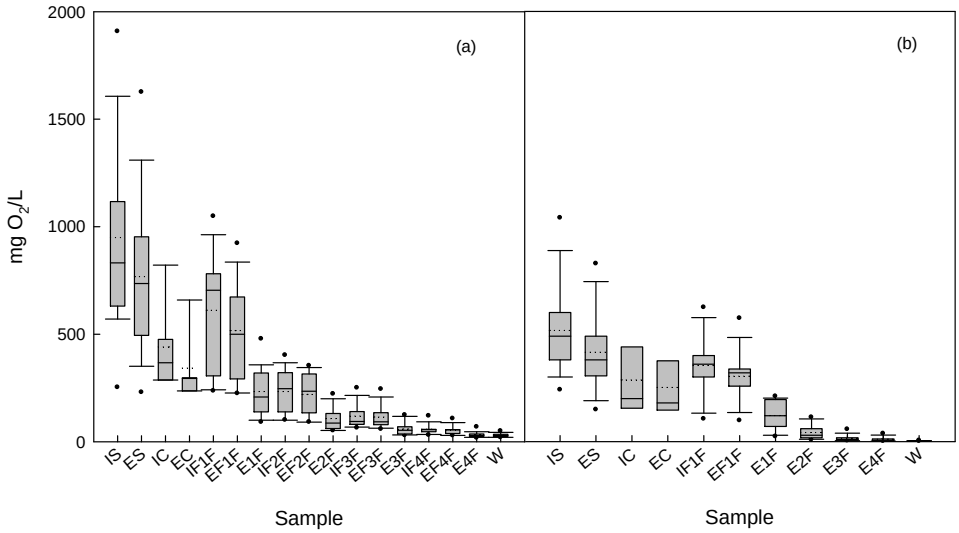

Figure 4. Box plots of the evolution in organic mater (COD and BOD_5) through the depuration process.

The concentration of organic matter (COD and BOD_5) gradually decrease throughout the depuration process (Figure 4). The reduction in organic matter could be due to the retention of suspended solids of organic nature in the filter, in the clarifier and in the gravel bed, and also to the biodegradation of the organic matter by the living organisms on the gravel bed. A biofilm is generated over the gravel surface which is the main cause of the removal in soluble organic matter in each one of the symbiotic stages.

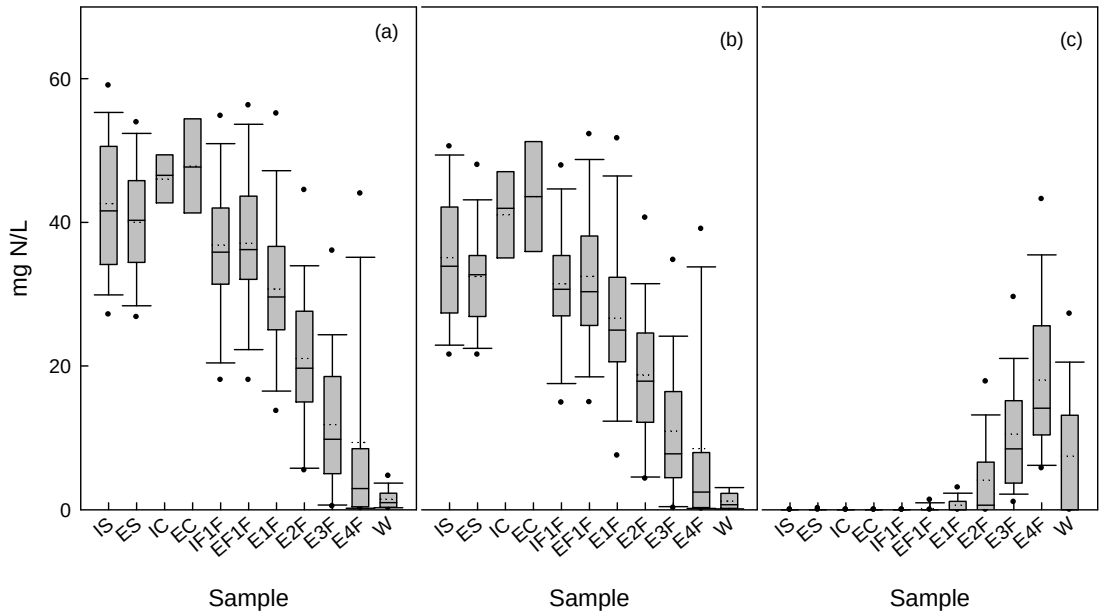

Figure 5. Box plots of the evolution in TKN a), N-NH_4^+ (b) and nitrates (c) through the depuration process.

TKN and N-NH_4^+ decrease along the depuration process (Figures 5a and 5b). A great similitude between both parameters in the last stage of symbiotic tretment is obtained, due to the descomposition by microorganisms of organic nitrogen to ammonia nitrogen. The overall ammonium removed is transformed to nitrates (Figure 5c). The aerobic conditions and the low level of organic matter in the last symbiotic beds favoured the nitrification. In most of the cases, the symbiotic system shows a high removal of ammonia. However, removal of total nitrogen would be very low because of nearly zero denitrification. With the final treatment in the wetland an important level of denitrification is achieved.

The main contribution to phosphorus removal was obtained in the first stage of the symbiotic treatment (Figure 6a). It could be due to the phosphorus retention in filters and gravel bed and also by the microorganisms assimilation of dissolved phosphate in the wastewater. No significant differences were obtained in the amount of phosphates (Figure 6b) through the symbiotic treatment stages (transformation of organic phosphorus to phosphates is equilibrated with phosphates assimilation by microorganisms).

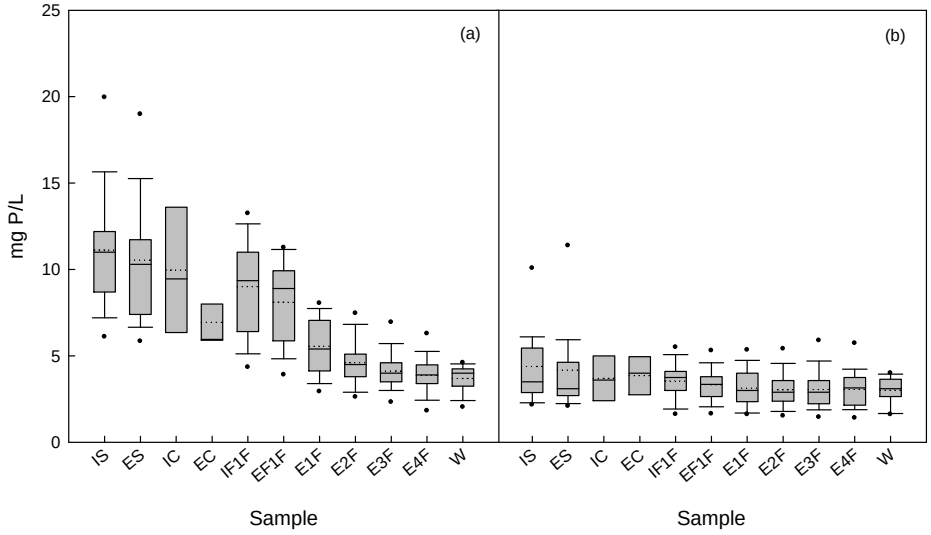

Figure 6. Box plots of the evolution in TP (a) and phosphates (b) through the depuration process.

Characterization of effuent

Table 1 shows the minimum, maximum and average value (parenthesis) of each one of the parameters studied for the effluent of the fourth treatment phases, as well as the percentage removal. The effluent complies with the Directive 91/271/ECC effluent requeriments of $\leq$ 35 mg/L TSS, $\leq$ 125 mg/L COD and $\leq$ 25 mg/L BOD_5. High removal efficiencies were obtained for TSS, COD and BOD_5. In the case of nitrogen and phosphorus species, there is a great variability on the percentage removal, maybe due to the high sensibility of the microorganisms, responsible of their elimination, to variations of their environmental conditions.

Table 1.- Characteristics of wastewater at the outlet of the plant and percentage removal.

	Outlet	Removal (%)
pH	6.8-8 (7.24)	-
Conductivity (mS/cm)	1.62-3.02 (2.31)	-
DO (mg O_2/L)	1-8.02 (4.20)	-
T (ºC)	14-29.3 (19.98)	-
TSS (mg/L)	2-31 (13.2)	80.8-99.5 (96.0)
COD (mg O_2/L)	16-63 (32.5)	85.6-98.7 (95.6)
BOD_5 (mg O_2/L)	0-22 (6.24)	94.4-100 (98.7)
TKN (mg N/L)	0.2-45.8 (7.68)	35.8-99.7 (85.6)
$N\text{-}NH_4^+$ (mg N/L)	0.1-40 (6.86)	27.7-99.8 (83.8)
Nitrates (mg N/L)	4.4- 43.4(18.2)	-
TP (mg P/L)	1.1-7.7 (4.02)	6.1-85.5 (60.9)
$P\text{-}PO_4^{3-}$ (mg P/L)	0.5-6.57 (3.27)	-

Conclusions

Considering the experimental results, before more than a year of operation of the cited wastewater treatment plant, it can be concluded that the treatment plant installed at the University of Murcia is able to treat high fluctuations in influent load and provide an effluent that complies with the Directive 91/271/ECC effluent requeriments. Besides, with the observation of the plant operation, a quick stars-up of the process, a great simplicity of operation and maintenance, no umpleasant odours and low generation of sludge were observed. So, symbiotic depuration could be considered a promissing alternative to conventional wastewater treatment systems.

Denitrification in an anoxic rotating biological contactor under two carbon/nitrogen ratios

Susana Cortez*, Pilar Teixeira, Rosário Oliveira, Manuel Mota
IBB – Institute for Biotechnology and Bioengineering, Centre of Biological Engineering,
University of Minho, Campus de Gualtar, 4710–057 Braga, Portugal.

Keywords: anoxic rotating biological contactor, C/N ratio, denitrification
Topic: Environmental engineering and management

Abstract

The aim of the present work was to compare the performance of an anoxic bench-scale rotating biological contactor (RBC), in terms of the denitrification process, applied to treat synthetic wastewater under two carbon/nitrogen (C/N) molar ratios (1.5 and 3). The average removal efficiency in terms of nitrogen-nitrate was of about 90.4% at a C/N=1.5 lowering to 73.7% at a C/N=3. Considering carbon-acetate removal an overall efficiency of 82.0% and 63.6% was attained at a C/N ratio of 1.5 and 3, respectively. These results evidence that, for the tested conditions, the use of C/N=1.5 is advantageous.

The increase of nitrogen-nitrate and carbon-acetate influent concentrations, keeping C/N constant, and the decrease of hydraulic retention time (HRT) had a slight negative effect in terms of substrate removal.

The accumulation of nitrite was observed in both experiments, which could probably be lowered with an increase in phosphorus influent concentration.

Results show that an anoxic RBC using acetate as a carbon source is a convenient and reliable process for the removal of nitrate from wastewater.

1 Introduction

Nowadays, the presence of nitrate in wastewater is considered a critical problem. The processes used for treating nitrate-rich wastewater include reverse osmosis, ion exchange, electrodialysis and biological nitrate reduction (denitrification). Denitrification has been shown to be more economical and practical and the most promising and versatile approach among all (Mateju et al., 1992). In this process, microorganisms first reduce nitrate (NO_3^-) to nitrite (NO_2^-) and then produce nitric oxide (NO), nitrous oxide (N_2O), and, finally, nitrogen gas (N_2), in the absence of dissolved oxygen (DO) or under limited DO concentrations (Tchobanoglous and Burton, 1991).

Most denitrification processes rely on heterotrophic bacteria so, when the wastewater does not contain biodegradable organic carbon compounds, these have to be added (Beaubien et al., 1995). Acetate has been reported to give high denitrification rates in most cases (Hallin et al., 2006).

Cervantes et al. (1999) reported that for high denitrifying efficiencies the carbon to nitrogen ratio was the main parameter of control to achieve a dissimilative respiratory process.

A rotating biological contactor is an attached growth bioreactor that offers an alternative technology to the conventional activated sludge process and is used for both municipal and

industrial wastewater treatment. A RBC unit typically consists of a series of closely spaced discs that are mounted on a common horizontal shaft and are partially or completely submerged in wastewater. The shaft continually rotates and a biofilm is established onto the entire surface area of the media, which metabolizes the organic materials contained in the wastewater. Due to its advantages: simplicity of operation, short hydraulic retention time (HRT), low land area requirement, low operating and maintenance cost and high biomass concentration per reactor volume, RBCs constitute a very unique and superior alternative technology for carbon oxidation, nitrification, denitrification and phosphorus removal. Although in the last decade RBCs tightly closed to avoid air entrance have started to be used for denitrification, few studies have still been conducted with anoxic RBCs (Cortez et al. 2008).

In this study the denitrification efficiency of an anoxic bench-scale RBC was followed under two carbon/nitrogen (C/N) molar ratios: 1.5 and 3, with acetate as carbon source.

2 Materials and methods

2.1 Anoxic rotating biological contactor and operation

The anoxic RBC single-stage system consisted of 8 polymethylmethacrylate (PMMA) discs (diameter = 130 mm, thickness = 3 mm, 20 mm interspace) mounted on a horizontal shaft, having a working volume of 2.5 L. The rotating biological contactor was operated at a rotational speed of 4 rpm and the temperature was maintained at 28 ºC by means of a heating jacket. The submergence of the discs was 93.5%. Prior to continuous operation the reactor was inoculated with microorganisms, acclimatized to acetate and nitrate, collected from an activated sludge tank from a wastewater treatment plant. Microbial attachment onto the discs was allowed to occur in batch mode and a visible attachment of biomass on the discs was noticed after 4 days of inoculation. On day 6, the anoxic RBC mixed liquor was removed, the reactor was re-filled and started to be fed continuously with synthetic wastewater. The time “zero” of operation was considered when the hydraulic retention time was adjusted to 10 hours. Two days after that, samples started to be collected.
The synthetic wastewater contained nitrate, acetate as carbon source, a phosphorus concentration of 10 mg P/L and trace elements.
To evaluate the reactor efficiency, during the assay, nitrogen-nitrate concentration was doubled at the 8th day of operation and carbon-acetate concentration was adjusted to keep the ratio C/N constant (according to the experiment, C/N=1.5 or C/N=3). In both experiments the hydraulic retention time was also changed and reduced from 10.00 h to 5.68 h, as shown in Table 1.

Table 1. Operation parameters of the anoxic RBC.

Days of operation	HRT (h)	N-NO_3^- (mg/L)
0 - 8	10.00	50
8 - 15	10.00	100
15 - 22	6.84	100
22 – 28	5.68	100

The study was conducted for a period of 28 days (for each C/N ratio). The nitrogen-nitrate range selected is typical of concentrations found in agricultural and industrial wastewaters (Bickers and Oostrom, 2000).

2.2 Sampling and analysis

During the course of continuous operation, samples of the RBC influent and effluent were collected routinely and analysed for various parameters such as nitrate, acetate and nitrite. In order to remove interfering suspended particles samples were filtered over a 0.2 µm membrane filter. Nitrate and acetate concentrations were measured by HPLC in an organic

acids column (*Varian Metacarb*, type 67H, 9 µm, 300 mm long, 6.5 mm internal diameter). Nitrite was determined by a colorimetric method using N-(1-naphthyl)-ethylene-diamine, according to the standard methods (APHA, 1989). Periodically, gas samples were analysed by gas chromatography.

3 Results and discussion

Variations in the removal efficiencies of nitrogen-nitrate ($N\text{-}NO_3^-$) and carbon-acetate ($C\text{-}CH_3COO^-$) as a function of operating time are shown in Figure 1 (a) and (b), respectively.

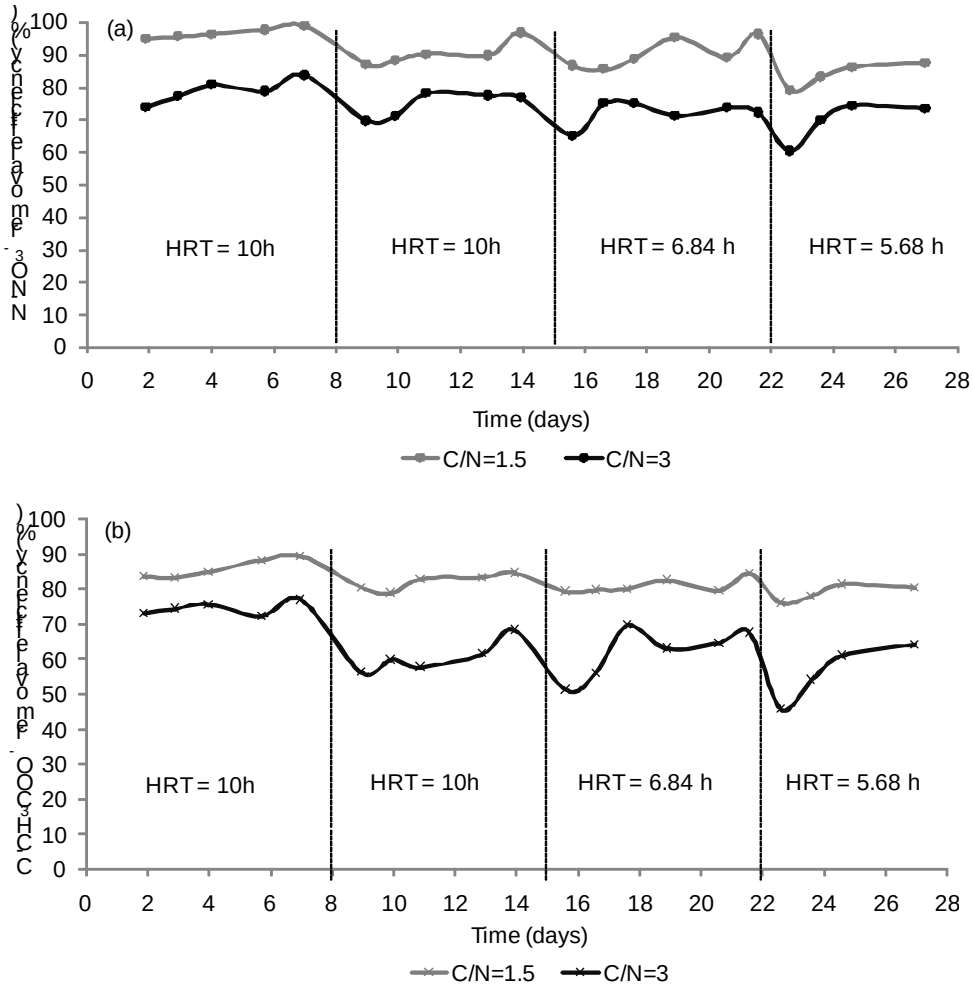

Figure 1. Nitrogen-nitrate (a) and carbon-acetate (b) removal efficiency along the time at two C/N ratios: 1.5 and 3.

The bench-scale RBC showed a high nitrate removal percentage in both experiments. $N\text{-}NO_3^-$ overall efficiency was of about 90.4% at a C/N=1.5 lowering to 73.7% at a C/N=3 (Figure 1 (a)). Considering carbon-acetate removal (Figure 1 (b)), an overall efficiency of 82.0% and 63.6% was attained at a C/N ratio of 1.5 and 3, respectively. These results evidence that, an increase in the C/N ratio from 1.5 to 3 was accompanied by a decrease in substrate removal efficiencies. Consequently, in the experiment at C/N=3 the biomass present in the anoxic RBC did not metabolize all the substrates and as a result they were accumulated along the time. For economical and environmental reasons the use of C/N=1.5 is advantageous.

The maximum substrate removal efficiencies were obtained in the first period of operation, with an influent nitrogen-nitrate concentration of 50 mg $N\text{-}NO_3^-$/L and a hydraulic retention

time of 10 h. The removal efficiencies were slightly lowered by a twofold increase in nitrate and acetate loading rate and a decrease in HRT.

Data presented in Figure 2 show the accumulation of nitrogen-nitrite ($N\text{-}NO_2^-$). Accumulation of nitrite has been frequently found in biological denitrification processes. Several factors such as oxygen concentration, pH, temperature, biofilm composition, toxic substances, influent nitrate concentration, available and type of carbon source and carbon to nitrogen ratio influence nitrite accumulation (Moreno et al., 2005). It is very important to avoid nitrite accumulation because it can lead to inhibition of bacterial development. Moreover, high nitrite concentration is highly undesirable once nitrite is more toxic than nitrate (Hunter, 2003).

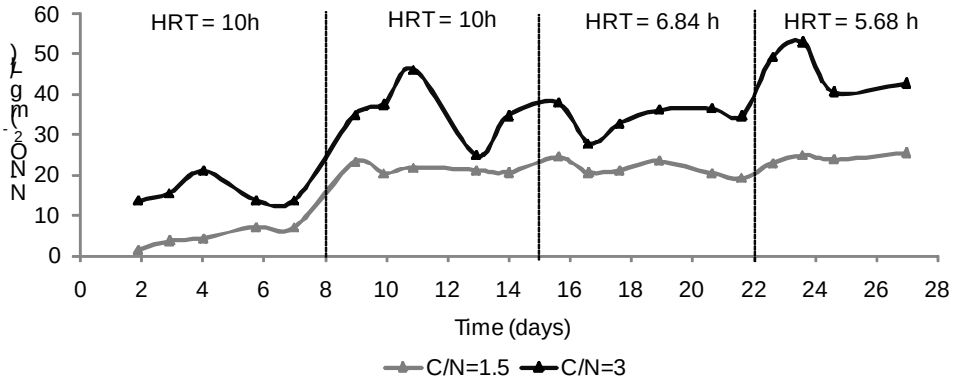

Figure 2. Nitrogen-nitrite effluent concentration along the time at two C/N ratios: 1.5 and 3.

An insufficient phosphate level also leads to nitrite accumulation (Reisinger et al., 1989). In order to reduce the formation of nitrite, Teixeira and Oliveira (2000) increased the phosphorus concentration tenfold (from 2 mg P/L to 20 mg P/L) which resulted in a drastically decrease in the accumulation of nitrite and induced a good RBC performance. It can be speculated that the influent phosphate concentration limited the conversion of nitrite to nitrogen gas. Alternatively, the accumulation of nitrite can result from the microbial population present inside the RBC rich in nitrate reducing bacteria.

4 Conclusions

The RBC had a very good performance at C/N=1.5, using acetate as carbon source, attaining a nitrate removal of about 90%, that could probably be enhanced with an increase in phosphorus concentration. As a general conclusion, the RBC proved to be very robust in coping with high nitrate loads and shock loads.

Abstract – Phenol and phenolic compounds have been listed as priority-pollutants by Environmental Protection Agency (EPA – USA). They are often found in industrial effluents such as from pulp and paper, plastics and synthetic polymer, pharmaceutical, pesticide, oil and petrochemical industries. Most of the traditional wastewater treatments have shown inefficiency against high phenol concentrations. This work aims to treat phenol solution via Advanced Oxidation Processes (AOP´s) to enhance medium biodegradability and using it as an effluent in a continuous activated sludge biological process. The purpose of the pre-treatment is to modify the phenol structure leading it to its byproducts such as aromatics compounds and carboxylic acids. The experiments have shown the effectiveness of the pre-treatment by the biodegradability parameter BOD_5/COD which was achieved 0.35 at 30 min of Fenton reaction in the following experimental conditions: $[phenol]_0$ = 1000 $mgC.L^{-1}$; $[FeSO_4]$ = 1 mM and H_2O_2 was added, along 2 hours of reaction, with a constant flow of 0.1 $L.h^{-1}$ (8.33 $mmol.min^{-1}$).

KEYWORDS: wastewater, phenol, process integration, activated sludge, advanced oxidation process and synthetic polymer, pharmaceutical, pesticide, oil and petrochemical industries.

. INTRODUCTION

Due to the toxic nature of some phenolic compounds the Environmental Protection Agency (EPA-USA) has set a water purification standard of less than 1 part per billion (ppb) of phenol in surface waters (Melo *et al*., 2005). They are often found in industrial effluents such as from pulp and paper, plastics

Conventional oxidative methods for the wastewater treatment utilize the combination of biological, physical and chemical treatments. Biotreatment processes tend to be very large due to the slow rate of the biological reactions; physical methods generally transfer waste components from one phase to another; chemical treatment, such as chlorination, can result in the formation of chlorinated phenols and their byproducts which are as toxic and non-

biodegradable as the original medium (Kusic and Koprivanac, 2006).

Advanced Oxidation Processes (AOP´s) have been used as one of the most effective processes to remove organic pollutants from aqueous solutions containing soluble organic compounds that are either toxic or non-biodegradable. AOP´s involve the generation of the hydroxyl radical (•OH), which has a very high oxidation potential and is able to oxidize almost all organic pollutants (Esplugas *et al*., 2002; Moraes, *et al*, 2004; Kusic and Koprivanac, 2006). Although these processes have shown high efficiency for water and wastewater treatment, they have high costs related to investment (complex installations) and operation (high consumption of energy and/or reagents), according to Esplugas *et al.*, 2002.

A promising alternative to complete oxidation of biorecalcitrant wastewater is the use of an AOP as pre-treatment to convert the highly toxic organic compounds to readily biodegradable intermediates (Devlin and Harris, 1984), followed by biological oxidation of these intermediates to biomass and water (Hsu *et al*, 2004; De Morais and Zamora, 2005; Al Momani, 2006).

The ratio (BOD_5/COD) has been used as a biodegradability paramerter, representing a fraction of organic material easily assimilate microorganisms. Solutions with ratio DBO_5/DQO > 0.4 has been considered as organic matter thoroughly biodegradable (Chamarro *et al*., 2001).

Fenton's reaction may be recommended as a pre-treatment process to enhance later microbial transformation, lowering the operational costs, by increasing its biodegradability, generally through the cleavage of large organic compounds into smaller ones (Walling , 1975; Chamarro *et al*., 2001; Zazo *et al*, 2005).

2. MATERIAL AND METHODS

The reagents used in the pre-treatments runs were carried out via Fenton and photo-Fenton processes were 1000 $mgC.L^{-1}$ of phenol (C_6H_5OH), 8.33 $mmol.min^{-1}$ of hydrogen peroxide (H_2O_2; 30% m/m), 1 $mg.L^{-1}$ of ferrous sulphate heptahydrate ($FeSO_4.7H_2O$) and sulfuric acid concentrated (H_2SO_4). A solution 0,1M of sodium hydroxide (NaOH) was prepared to stop the reaction of the samples to be analyzed. All the reagents were analysis grade. A peristaltic pump (Ismatec, model IPC-4) was used to add the hydrogen peroxide (H_2O_2; 30% m/m) with a constant flow of 0.1 $L.h^{-1}$ (8.33 $mmol.min^{-1}$).

The apparatus used were a photochemical reactor that consists of an inox cylinder with mirrored wall presenting 12 black light fluorescent lamps (Sylvania, 40 W each) connected in it. At the center of this reactor is attached a borosilicate glass tube (inner diameter = 3 cm; length = 100 cm), through which flows the effluent to be treated (upper flux). The upper part of the reactor is kept a exhaust system to refrigerate the internal part from the heat of the lamps. The reactor is attached to 20L mixing tank connected to a centrifuge pump for the effluent recirculation (200 $L.h^{-1}$).

The procedure was initially, filling the mixing tank with 9.4 L of distillated water. Afterwards, the centrifuge pump (200 $L.h^{-1}$) and the 12 fluorescent lamps were switched on. It was been added the phenol aqueous solution (C_6H_5OH; 13.25 g in 500 mL of distillated water). The pH of the reactor solution was adjusted to 3.0 (without further control) with concentrated sulfuric acid (H_2SO_4). After 5 min of recirculation, the first sample was collected them the time begun with the addiction of both ferrous sulphate solution ($FeSO_4.7H_2O$; 2.82 g in

250 mL of distillated water) and H_2O_2 was added via a persitaltic pump (Ismatec, model IPC-4) with a constant flow of 0.1 $L.h^{-1}$ (8.33 $mmol.min^{-1}$), along 2 hours of reaction. All runs were carried out at room temperature (≈ 29 ºC).

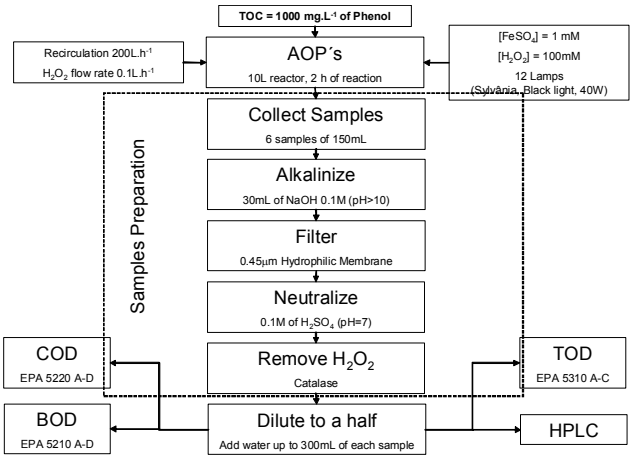

Figure 1: Procedure of sample preparation

The sample´s preparation were as follows: pH ajust to 10.0 using 0.1 M NaOH solution to stop the reaction. Afterwads, the samples were filtered with 0.45 μm hydrophilic membrane (Durapore, Millipore) to remove ions ferrous precipitaed (Zazo *et al*., 2007), added 0.1 M sulfuric acid to neutralize the samples and, finally, enzyme catalase to remove H_2O_2 residual from the samples to be analised, as observed in Figure 1.

All samples were diluted to a half to simulate the condition of the input effluent in the pos-treatment (biological processs), because, in previous experiments (Sassano *et al*., 2007), the wastewater was fed, simultaniously, with the same flow as the nutrients (1:1). A scheme of the integrated processes (photochemical and biological reactors) can be seen in Figure 2.

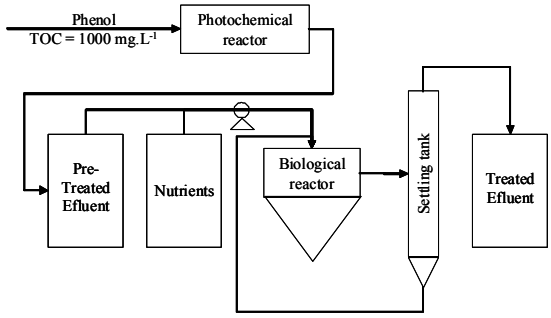

Figure 2: Scheme of the integrated processes

The analytical determinations were as follows:

Biological Oxygen Demand (BOD_5) through a manometric BOD measurement device (OxiTop 12 WTW). Measurement is based on pressure measurement in a closed system: microorganisms in the sample consume the oxygen and form CO_2. This is absorbed by NaOH, creating a vacuum which can be read directly as a measured value (US Standard Methods 5210 D).

Total Organic Carbon (TOC) performed by total organic carbon analyzer TOC-5000A (Shimadzu) resulting from a diference of Total Carbon (TC) ande Inorganic Carbon (IC) based on catalyst combustion method (TC) and acidification method (IC).

Chemical Oxygen Demand (COD) through a COD solution A+B (Merck). The water sample is oxidized with a hot sulfuric solution of potassium dichromate, with silver sulfate as catalyst. Chloride is masked with mercury sulfate. The concentration of unconsumed yellow $Cr_2O_7^{2-}$ ions or, respectively, of green Cr^{3+} ions is then determined photometrically (EPA 410.4, US Standard Methods 5220 D, and ISO 6060).

High Performance Liquid Chromatography (HPLC) equipped with software LCMS Solutions, liquid chromatograph LC-10ADvp, degasser DGU-14A, UV-VIS detector SPD-10AV vp , system controller SCL-10A vp

and column Supelco C18 (Shimadzu). The mobile fase used was water (A) and acetonitrile (B) with a gradient from B to A: 0min, 18%; 3 min, 18%; 15 min, 58%; 17 min, 58%; 19 min, 18% at 0.7 mL.min^{-1} and wavelength of 270 nm. The time retentions of phenol, cathecol and hydroquinone were 14.5, 8.0 and 5.0 min respectively.

3. RESULTS AND DISCUSSION

3.1 Pre-treatment: Fenton Reaction

In the Fenton's experiment the 12 fluorescent lamps were switched off. Considering the dilution step (1:1), the TOC values were almost constant (460 mgC.L^{-1}), showing that the organic matter remained at the solution along the 30 min of time reaction.

By the HPLC analysis, it could be observed the decay of phenol concentration by 76%, the formation of 1.13 mmol.L^{-1} of cathecol and 0.64 mmol.L^{-1} of hydroquinone at 30 min of reaction as byproducts of the degradation, as observed in Figure 3.

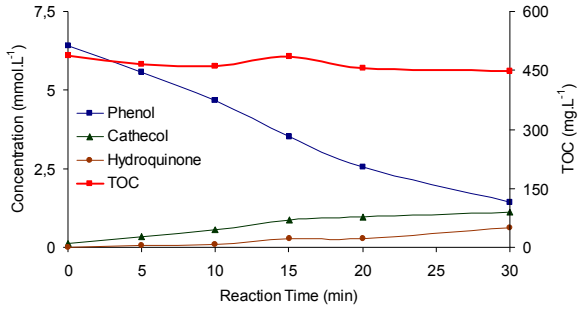

Figure 3: TOC, [phenol], [cathecol] and [hydroquinone] from diluted samples (1:1) along Fenton reaction ([phenol$_0$] = 1000 mgC.L^{-1}, [Fe^{2+}] =1 mg.L^{-1}, H_2O_2 rate feed = 8.33 mmol.min^{-1} and pH$_0$ = 3.0).

The COD results have shown a decrease of the initial value from 2024 mgO_2.L^{-1} to 634 mgO_2.L^{-1} in 30 min of reaction, representing 69% removal of COD.

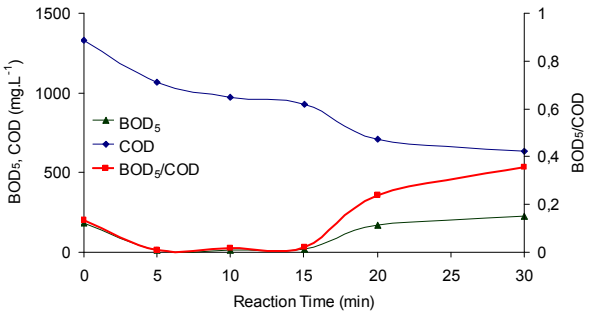

Figure 4: COD and BOD_5 along Fenton reaction, [COD_0] = 2024 mgO_2.L^{-1}.

From BOD analysis, it could be observed only at zero, 20 and 30 min using the same scale factor for the manometric device, showing that the BOD values from samples 5, 10 and 15 min were lower than the BOD expected value that refers to a chosen factor. The higher BOD value was 225 mgO_2.L^{-1} for the 30 min sample.

The best biodegradability factor BOD_5/COD for the samples of the Fenton experiment was 0.35 at 30 min of reaction, indicating the technical feasibility of the pre-treatment, as observed in Figure 4.

3.2 Pre-Treatment: photo-Fenton Reaction

For the photo-Fenton experiment, considering the dilution step (1:1), the TOC values were almost constant in 500 mgC.L^{-1}, showing that the organic matter remained at the solution along the 30 min of time reaction.

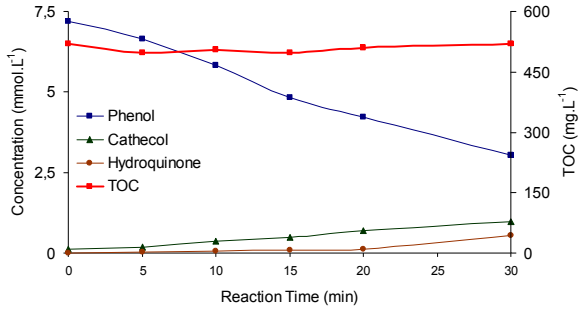

Figure 5: TOC, [phenol], [cathecol] and [hydroquinone] from diluted samples (1:1) along photo-Fenton reaction ([$phenol_0$] = 1000 $mgC.L^{-1}$, [Fe^{2+}] =1 $mg.L^{-1}$, H_2O_2 rate feed = 8.33 $mmol.min^{-1}$ and pH_0 = 3.0).

By the HPLC analysis, it could be observed the concentration reduction of phenol by 57%, the formation of 0.69 $mmol.L^{-1}$ of cathecol and 0.55 $mmol.L^{-1}$ of hydroquinone at 30min of reaction, showing the production of byproducts, as observed in Figure 5.

The DOC results have shown a decrease of the initial value from 1333 $mgO_2.L^{-1}$ to 1017 $mgO_2.L^{-1}$ in 30 min of reaction, representing 24% removal of DOC.

From BOD analysis, it could be observed only at zero, 5, 20 and 30 min using the same scale factor for the manometric device, showing that the BOD values from samples 10 and 15 min were lower than the BOD expected value that refers to a chosen factor. The higher BOD value was 195 $mgO_2.L^{-1}$ for the 30 min sample.

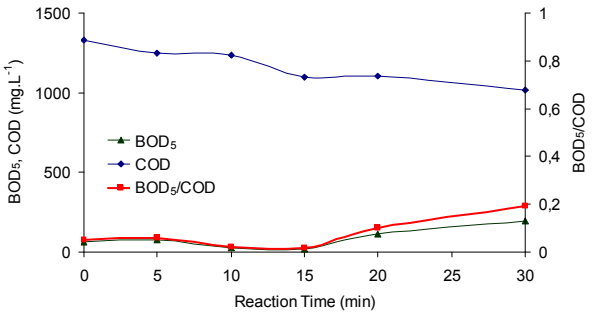

Figure 6: COD and BOD_5 along photo-Fenton reaction, [COD_0] = 1333 $mgO_2.L^{-1}$.

The best biodegradability factor BOD_5/COD for the samples of the photo-Fenton experiment was 0.19 at 30min of reaction, showing the enhancement of the pre-treatment, as observed in Figure 6.

4. CONCLUSIONS

The Fenton and photo-Fenton conditions used in the experiments have shown values of TOC constants along 30 min of reaction, keeping the organic matter at the media.

From HPLC results we could observe decay of phenol concentration (76%) and formation of byproducts such as cathecol (1.13 $mmol.L^{-1}$) and hydroquinone (0.64 $mmol.L^{-1}$) at 30 min of Fenton reaction, showing structure modification from the initial compound into its derivates.

Both Fenton and photo-Fenton processes have shown high efficiency in forming intermediates that were much easier assimilated by the activated sludge (BOD_5 = 225 $mgO_2.L^{-1}$) and an organic matter decay oxidize chemically (69% COD removal), representing biodegradability values of 0.35 (BOD_5/COD) at the same 30 min of Fenton's reaction, this value is very close to 0.4, indicating that this effluent could be considered biodegradable (Chamarro *et al.*, 2001).

The experimental results show that a wastewater containing 1000 $mgC.L^{-1}$ of phenol can be pre-treated via Fenton reaction, along short time (around 30 min), allowing an integration with a conventional biological process (activated sludge, for example), reducing energy and material costs.

Further studies to identify more byproducts from phenol degradation via HPLC, could be interesting as much as the use of bioreactors that enable the pH and DO (Dissolved Oxygen) control., letting a much favor medium for microbial action, allowing kinetics parameters optimization for the continuous biological system, increasing the process efficiency and costs reduction.

5. ACKNOWLEDMENTS

The authors appreciate financial support from FAPESP, CAPES, FUSP and CEPEMA.

Introduction

Despite of the employment of physical-chemical and biological processes, some industries have difficulty to adequate the treated effluents to the discharge standards established by local environmental legislation such as the fine chemicals industry of this study. The referred industry is an all-purpose plant, with chemical synthesis being carried in a batch mode, where most processes occur in aqueous phase, some of them using organic solvents. There are three main lines of products: stilbene compounds, whitening agent DSBP (Tinopal CBS), finishing and textile processing products. The wastewater generated in the production of stilbene compounds are the main source of chemical oxygen demand (COD) being diluted in the WWTP with less concentrated effluents from other production processes. The complex structure of these constituents, having stilbene as the molecule base (trans-1,2-diphenylethylene) replaced with amine and sulfate groups (high MW, many ramifications, presence of HSO_3^- groups), high salinity (12,000 mg NaCl/L, on average) and the high variability on the wastewater composition, providing to the influent of the WWTP high recalcitrance or low biodegradability characteristics (Stoll et al., 1998).

The treatment system is based on a sequence of coagulation/flocculation processes (with the addition of aluminum sulfate and flocculating agent Magnafloc 155) and activated sludge (operating with hydraulic retention time of approximately 48 h), producing a treated wastewater with COD value (800 mgO_2/L, on average) higher than the discharge limit established by local legislation (250 mg O_2/L). The industry is seeking to reach this COD value without success. So, the objective of the present study was to evaluate the impact of operational parameters in the performance of the activated sludge system of the WWTP to improve its performance and to attain lower COD values.

Material and Methods

Kinetic model: a descriptive kinetic model of the organic matter removal process, based on Monod type functions, was employed to estimate kinetic parameters from WTP and posterior evaluation of the response sensibility of the biological system to variations in the operational conditions and estimated kinetic parameters. The kinetic model employs two variables of state (carbonaceous substrate and biomass concentrations) and four kinetic parameters necessary for the description of the organic matter removal in WWTP. To develop the model some hypotheses were considered in the mass balance calculation, for both substrate and biomass concentrations, such as continuous system where all biomass is recycled to aeration tank, i.e., does not have any discard of excess sludge; the cell growth rate is proportional to the substrate concentration (expressed as COD) and the dissolved oxygen concentration in the aeration tank; cell lysis generates biodegradable material and this rate is proportional to the cell quantity in the aeration tank; and the influent (of the aeration tank) and the treated effluent (from settler) streams do not contain biomass.

The equations 1 and 2 refer to the mass balance for each component. These equations resulted in a system of ordinary differential equations that describes the organic matter consumption rate and cells production rate.

Mass balance for biomass:

$$\frac{dX}{dt} = \frac{1}{V}\left(F_2 X_R - F_3 X\right) + \mu_{\max} X \frac{S}{\left(K_S + S\right)} \frac{OD}{\left(K_{OD} + OD\right)} \quad (1)$$

Mass balance for substrate:

$$\frac{dS}{dt} = \frac{1}{V}\left(F_1 S_a + \left(F_2 - F_3\right)S\right) - \mu_{\max} X \frac{S}{\left(K_S + S\right)} \frac{OD}{\left(K_{OD} + OD\right)} + m X \quad (2)$$

where:
dX/dt – biomass variation with the time (mg VSS/d.L); dS/dt – substrate variation with the time (mg COD/d.L); X – biomass concentration into reactor (mg VSS/L); X_r – biomass concentration in the settler bottom (mg VSS/L); V – reactor volume (L); S_a – influent substrate concentration (mg COD/L); S – substrate concentration into reactor (mg COD/L); F_1 – reactor influent feed rate (L/d); F_2 – recycle feed rate (L/d); F_3 – reactor effluent feed rate (L/d); OD – dissolved oxygen concentration into reactor (mg O_2/L); μ_{max} – maximum specific growth rate (d^{-1}); K_s – half saturation coefficient for carbonaceous substrate (mg COD/L); K_{OD} – dissolved oxygen coefficient (mg O_2/L); *m* – parameter related to the biodegradable material production from cellular lysis, proportional to cell concentration (mg COD/ mg VSS.d).

Data sets (including information about X, Xr, Sa, S, OD, V, F1, F2 and F3) obtained along 16 months (June 2004 to September 2005) of WWTP operation were used to determine the model parameters. Parameter estimation was conducted with MATLAB Optimization Toolbox (The Mathworks Inc.) by the minimization of squared residual error between experimental and estimated values (Eq. 3) through Nelder and Mead type simplex search method (Edgar and Himmenblau, 1988). A maximum of 10% in the experimental deviations were accepted for the parameter estimation.

$$Fobj = \sum_{i}^{ne} \sum_{j}^{np} w_1 \left(\left[S\right]_{\exp} - \left[S\right]_{calc}\right)^2 + w_2 \left(\left[X\right]_{\exp} - \left[X\right]_{calc}\right)^2 \quad (3)$$

where:
ne – experimental number; np – experimental data number in the experiment *I*; w_i – respective error for concentration measurement.

Model Sensibility: a study to consider the impact of kinetic parameters on process' performance prediction was carried considering variations (δ) of $\pm$ 5% in the initial value (base). The influence of the parameter p(i) on the component C concentration is given by Eq. 4.

$$\frac{dC_{(i)}}{dp} = \frac{C_{(i+\delta)} - C_{(i)}}{\delta} \quad (4)$$

The effects of these variations were analyzed on carbonaceous substrate and biomass concentrations. The sensibility was normalized by the maximum concentration value achieved by each component C, in the base case.

The model sensibility to the variations in the operational conditions, with variations (δ) of $\pm$ 5%, was evaluated in a similar way. In the WWTP sensibility analysis, the operational parameters were selected according to the influence it will exert on carbon removal and cell growth. Indeed, some of these parameters were variables of the system, such as: reactor influent flow (F_1), recycle flow (F_2), reactor effluent flow (F_3), substrate concentration into feed stream (S_a), dissolved oxygen concentration into reactor (OD), reactor volume (V) and biomass concentration into recycle from settler for reactor (X_R).

Pilot plant: the pilot plant employed in this study simulated the biological step of the WWTP. The plant was installed and operated in the industry, being continuously fed with effluent from industrial physical-chemical step added of sewage (generated in the industry) to supply essential nutrients (nitrogen and phosphorus) for the microorganisms. Indeed, phosphoric acid was also regularly added as extra nutrient source to obtain the recommended COD:N:P ratio (100:5:1).

The pilot unity was composed by an equalization tank (with usable volume of 800 L) and an aeration tank (180L), both of amiante coated with resin to avoid deterioration of the material and contamination of the effluent during the operation. The reactor tank was aerated by mechanical agitator and membrane tubular diffusers disposed in the bottom. This configuration leads to a continuous stirred tank reactor with perfect mixture (CSTR). After the aeration tank, there was a circular secondary settler (50L) of fiberglass of which left a recycle line of settled sludge, stabilizing biomass concentration inside the aeration tank. This pilot unit operated along 9 months with different hydraulic retention times (24, 48, 72 and 96 h). During these four regimes, sludge discharges were periodically made (around 6 L at alternated days) to stabilize the solids concentration in the reactor around 4500 mg/L and to renew the microbial flora. The feed stream of the pilot plant (effluent of the physical-chemical phase) had its pH adjusted with soda to values of 6.6 ± 0.4.

The performance of the plant in each HRT was evaluated through analysis of pH, COD (influent and effluent), VSS (into reactor) and turbidity (effluent). The F/M (feed to microorganism) ratio and SVI (sludge volumetric index) were also determined along the operation. The analytical methods were carried according the procedures described in Standard methods (APHA, 1992).

Results and Discussion

Table 1 shows the values obtained in the model identification using data collected in the industrial WWTP along 16 months. The data were divided in three phases, according temperature variation along the year, as the estimative of a unique set of parameters for the whole period was not representative of the WWTP experimental operation.

Table 1. Values estimated for the kinetic parameters.

Period	μ_{max} (d^{-1})	K_S (mgCOD/L)	K_{OD} (mgO_2/L)	m (mgCOD/ mg VSS.d)
Jun. 2004 to Oct. 2004	0.59	1112.9	0.000	0.25
Nov. 2004 to May 2005	0.18	344.7	0.026	0.40
Jun. 2005 to Sept. 2005	0.34	1185.9	0.000	0.29

The kinetic parameters presented in Table 1 indicate that from June to September/October, period in which the environment temperature is lower, the cells present high μ_{max} values. These results indicate that in these conditions a better cell replication occurs, independent of the dissolved oxygen concentration ($K_{OD} = 0$). The values obtained for the parameter *m* reveal a concordant behavior, indicating higher cellular lysis in the period with higher temperature (November to May). In this period, the cell growth rate is influenced by dissolved oxygen concentration. It may be considered that dissolved oxygen solubility in the aqueous phase diminishes with increasing temperature, reducing the availability of this nutrient to the cells.

A sensibility analysis of the variations (± 5%) in the WWTP operational conditions indicates similar impact for both + 5% and - 5%. It was observed that the state variables were influenced by different operational conditions, in descending order, the influent flow (F_1), the COD in feed (S_a) and the reactor volume (V). Considering that hydraulic retention time (HRT) is defined as the ratio between influent feed rate and reactor volume, there are an indirect influence of the HRT on COD removal that is also related with the load fed to the system. The operational conditions that more influenced cell growth were, in descending order, the reactor volume (V) and the effluent feed rate (F_3), indicating the possible occurrence of washout. In minor degree, the recycle flow rate (F_2) and

the COD influent concentration (S_a) also show some influence on the cell growth profile. An analysis using ±10 and ±50% of deviation did not result in a worse WWTP performance, being an indicative that the industrial system operates in its maximum limit: ± 5% variation would be so harmful than ± 50%.

Fig. 1 shows COD values in the influent and effluent streams of the activated sludge pilot plant along time of operation. It is observed that in none regime studied the COD attained the maximum value established by legislation (250 mg O_2/L). In the regimes operated with HRT of 24h and 48 h, it is verified a great fluctuation in influent COD values, probably due to little period of equalization of the influent. It caused an impact on microbial flora because there was not sufficient time to adaptation to variation of organic load. This fact is proven by high effluent COD values, mainly in the first regime (HRT of 24 h). In the regime operated with HRT of 48 h, the microorganisms had sufficient time to adapt to peaks of organic load and effluent COD values were less dispersed. In the other hand, in the regimes operated with HRT of 72 and 96 h, the relation between feed flow and equalization tank volume was sufficient to obtain a feed stream with more homogeneous organic load, improving consequently the stability and performance of the experimental system.

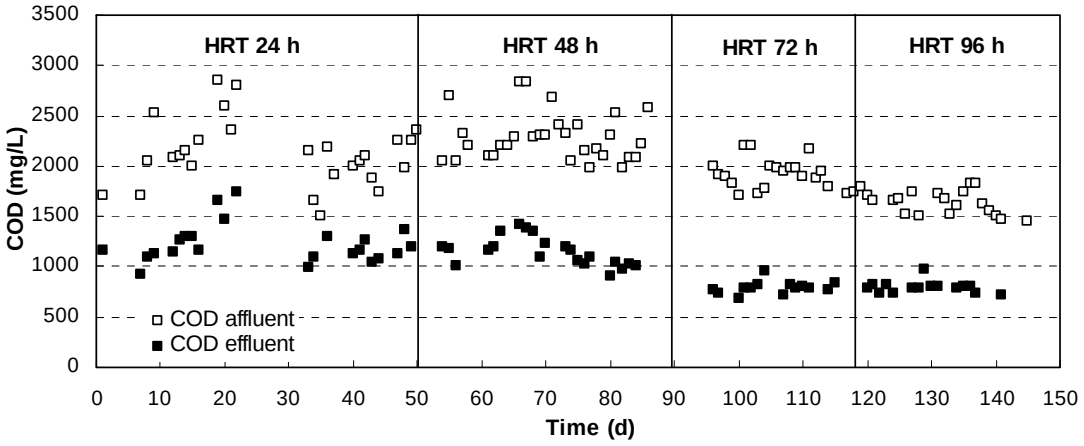

Fig. 1. Influent and effluent COD values along time of operation of the activated sludge pilot plant.

During pilot plant operation, it was observed that the increase of the HRT until 72 h improved the COD removal efficiency (Fig. 2). The COD removal efficiency varied in the first regime (30 to 55 %), increased in the second regime, attaining values up to 60 %, stabilizing around of this value in the third regime and decreasing in the last regime to 53 % on average.

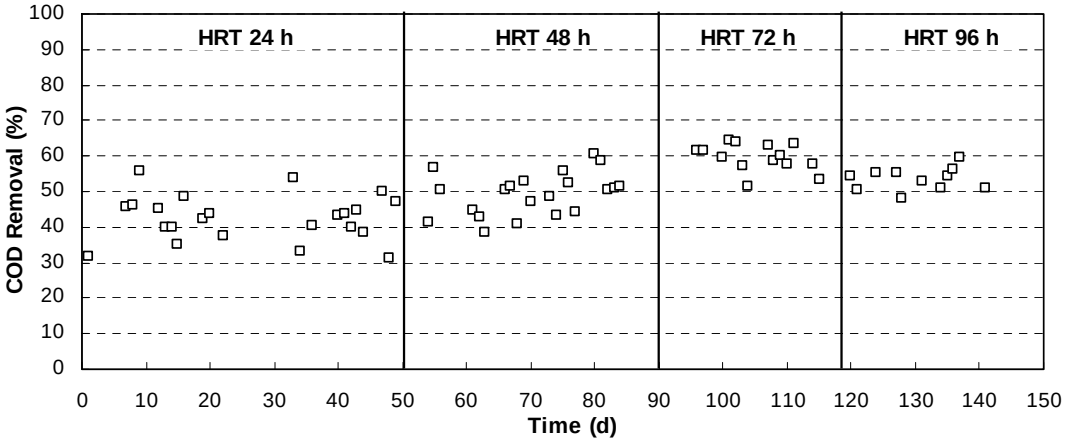

Fig. 2. COD removal efficiencies along time of operation of the activated sludge pilot plant.

Fig. 3 presents VSS concentration into aeration tank along time of operation. There was a great fluctuation of the VSS concentration, mainly in the 1st regime (HRT 24h), in which the biological system was more affected by variation of the influent stream. According Meltcalf and Eddy (1991), in an activated sludge conventional system the typical VSS concentration is in the range of 1500-3000 mg/L. Meanwhile, in extended aeration activated sludge systems the typical value is in the range of 3000-6000 mg/L. Analyzing the results can be concluded that, except for 1st regime, all other three regimes operated as extended aeration systems, because the VSS values stayed always above 3000 mg/L (4266 mg/L on average).

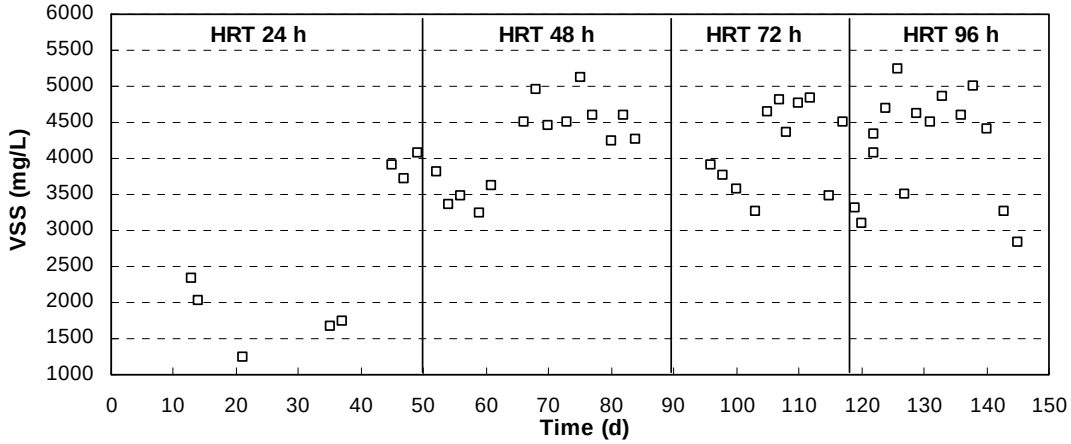

Fig. 3. VSS concentrations into aeration tank along time of operation of the activated sludge pilot.

Turbidity was measured in the final effluent to evaluate the system's behavior in relation to characteristics of the biomass. Fig. 4 illustrates the turbidity values obtained in the period studied. It was observed a great fluctuation in the 1st regime, probably due to washout of cells in the effluent stream and to bad operation of the system in this period. In the other regimes, the majority of the turbidity values were below of 30 NTU, indicating that follow to 1st regime, the system developed a biomass with better characteristics of flocculation and sedimentation. In relation to SVI, the majority of the values obtained were above of the range recommended in the literature for a good sedimentation (≤ 100 mL/g, Tchobanoglous et al., 2003). The regime operated with HRT of 72 h presented better results in terms of SVI, with more stable values varying between 109 and 135 mL/g.

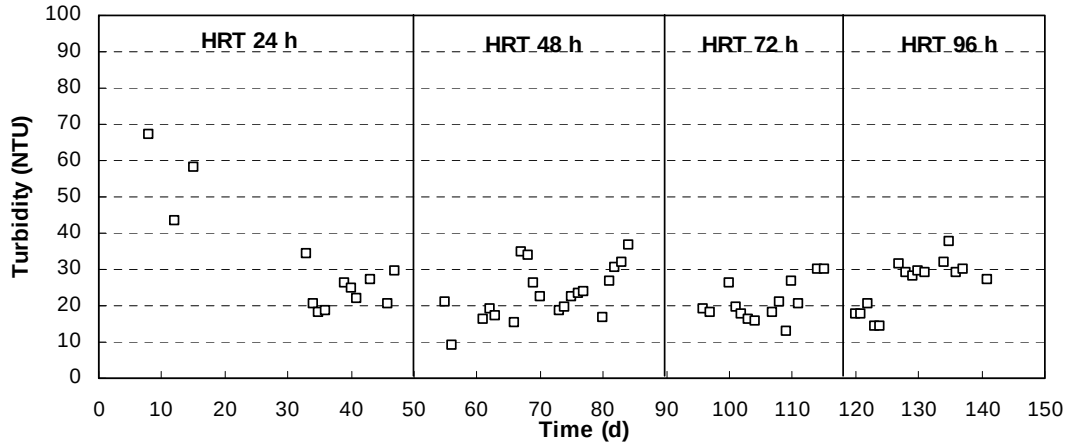

Fig. 4. Turbidity values in the effluent of the activated sludge system along time of operation.

The F/M ratio relates the available organic load with the quantity of biomass presents in the system, for a uniform substrate removal. When the substrate concentration diminishes, the search of food by microorganisms increases and consequently the organic matter removal efficiency also increases. The F/M values obtained along time of operation, except those for 1st regime (0.2 – 0.8 d^{-1}), were inside in the range recommended in the literature (0.08 – 0.15 d^{-1}) for extended aeration systems (Tchobanoglous et al., 2003).

Another important parameter evaluated was the temperature, measured daily into aeration tank. The temperature did not vary much along experimental runs, presenting values of (28 ± 2)ºC, (30 ± 1)ºC, (29 ± 1)ºC e (26 ± 2)ºC, in the regimes with HRT of 24, 48, 72 and 96 h, respectively. This parameter was appointed by mathematic model as of great influence in the WWTP performance. In fact, more stable values for temperature in the pilot plant resulted in values equally stable for COD removal efficiencies, mainly in the last two regimes (Fig. 2).

In representative absorption's spectra of the regimes operated with HRT of 48 and 72 h it was verified a little reduction of the absorbance after biological treatment. However, in the regimes with HRT of 24 and 96 h practically equal spectra were obtained for raw and treated effluents. These results are according with COD removals obtained, that were also higher in the regimes with HRT of 48 and 72 h. All spectra presented absorption's peaks in wavelengths of 210, 265 e 345 nm. Comparing the absorbance values in the wavelength of 265 nm for influent and effluent streams of the activated system it can estimate the optical brighteners' removal (22 and 45% for HRT of 48 and 72 h, respectively). Again, higher values were obtained in the regime operated with HRT of 72 h, confirming previous results obtained for COD removal. These results indicate that part of these compounds is removed in the activated sludge system, but it does not indicate necessarily that there was biodegradation because they can be removed by adsorption to sludge flocs.

Conclusions

Based on results obtained from sensibility analysis of operational conditions and kinetic parameters it can be concluded that the temperature is a control parameter that affects considerably the WWTP performance. In the sensibility study of kinetic parameters, m and μmax presented greater influence on analyzed variables (COD and biomass concentration). The saturation constants K_S and K_{OD} presented minor impact on response variables. In the sensibility study of operational conditions of WWTP, a variation of ± 5% was so harmful how much variations of 10 and 50%. Effluent COD was influenced by influent flow, influent COD and reactor volume, and consequently the HRT had indirect influence. Biomass concentration was influenced by reactor volume, effluent flow, recycle flow and influent COD. In the pilot plant operation, the HRT of 72h presented better results (COD removal efficiencies of 60%). These results show that other factors indeed temperature are important for the WWTP performance such as recalcitrance of the compounds present in the effluent.

Topic: Sustainable process-product development through green chemistry - Environmental engineering & management.

Abstract

The present work was undertaken, in order to evaluate the influence of the reactor contents recirculation on anaerobic digestion of biodegradable solid wastes like fruits, vegetables and grass. For that propose two reactors (R1 and R2) were tested with the same mixture of substrates (50% of fruits, vegetables and 50% of grass), at mesophilic range, having reactor R2 recirculation of its contents. Maximum specific methane production was 41.54 and 223.24 mL $CH_4.g^{-1}VS$ for reactors R1 e R2 respectively. The methane (%) presented in biogas was significantly higher for reactor R2 (70% CH_4) than for reactor R1 (45% CH_4). The recirculation had a considerably positive effect in methane production, which corresponds to better and higher energy recovery.

1 Introduction

Anaerobic digestion of solid waste is a topic of increasing interest throughout the world, because it is an effective method for the treatment of many biodegradable wastes, with three main advantages: production of biogas, what is considered a renewable energy source; production of compost that can be used as a soil fertilizer and the assurance of a lower contribution to greenhouse gases effects in comparison with other technological solutions.

Anaerobic digestion of waste is complex, because it involves several bacterial groups and many simultaneous degradation and product forming reactions catalysed by those microorganisms. There are several diagrams to represent the anaerobic digestion. Gujer and Zehnder (1983) presented a complex diagram with five simultaneous steps: hydrolysis, acidogenesis, acetogenesis, aceticlastic methanogenesis and hydrogenotrophic methanogenesis.

In Europe, the study of anaerobic digestion of solid wastes only started in the 1980's (Mata-Alvarez, 2002). After the energy crises of the 1970's and the global environmental considerations, such as greenhouse effect, anaerobic digestion process had a significant development. In 1998, only 13% of the anaerobic digestion capacity available in Europe was designed for digestion of residual municipal waste, but by the end of 2006 that capacity had reached more than 52% (De Baere, 2008). Nowadays, the construction of anaerobic digestion plants for municipal solid waste is about 2/3 for residual waste and 1/3 for source separated biowaste on digestion capacity (De Baere, 2006).

* Corresponding author. Tel + 351-21-8317172. E-mail:jvprata@deq.isel.ipl.pt

Another benefit associated with the anaerobic digestion is the possibility to reduce the amount of waste sent to landfill, which is a way to achieve the targets of European Directive 1999/31/CE for landfills.

Fruits and vegetables wastes represent potential energy resources (Gunaseelan *et al.*, 2004). This kind of waste is produced in great quantity from markets, restaurants, agriculture and others domestic activities. Also grass is a waste produced in significant quantities from golf clubs, stadiums and gardens.

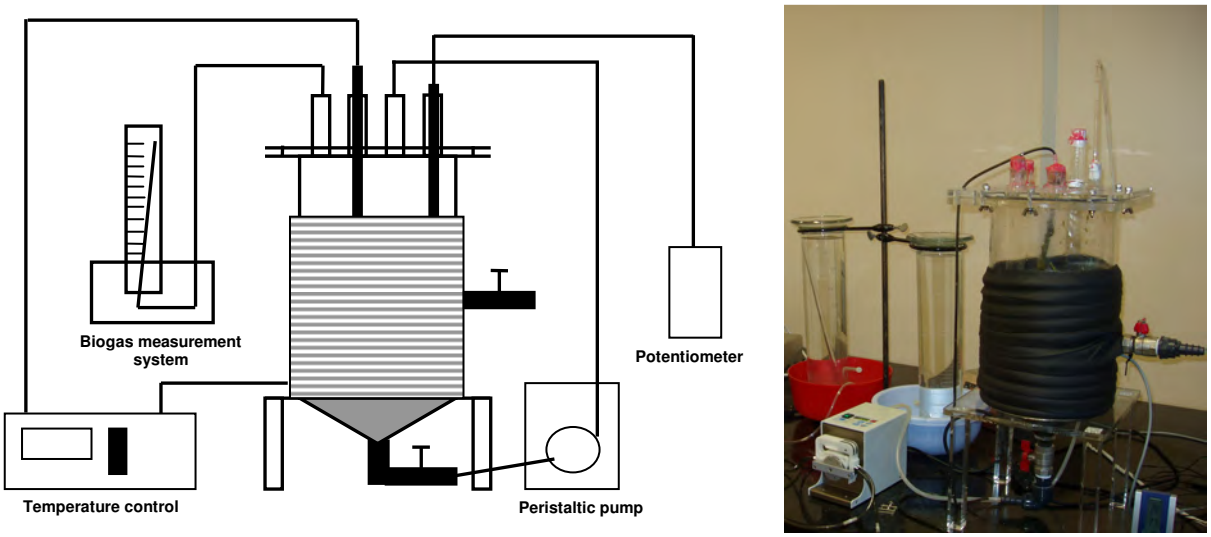
In Portugal, the first anaerobic digestion plant for waste was constructed only in the last years. In order to fully evaluate the overall anaerobic digestion process, particular attention should be devoted to the study of specific waste characteristics and process parameters. In fact, the ability to manage a biological process is deeply related to substrate biodegradability and proper control and operational conditions of the process.

The anaerobic digestion process depends on several environmental factors such as substrate concentrations, temperature, organic volatile acids, pH, alkalinity, inoculum and others. The recirculation of the content of reactors is one of the modes to promote de complete mixture of reactors, but this operation consumes enormous amounts of energy. Complete mixed reactors, usually, produces higher quantities of biogas and so this work aims to evaluated the effect of recirculation step in the performance of anaerobic digestion of biodegradable solid wastes like fruits, vegetables and grass.

2 Materials and methods

2.1 Apparatus

The experiments were carried out on two reactors with 10 L capacity. Schematic configuration and a view of reactors are shown in Figure 1. There reactors were operated in batch mode at mesophilic range. The content of reactor R2 was collected in the bottom and it was recycled to the top, with a peristaltic pump. Both reactors were mixed once per day, before the biogas collection. Experiments were run during 35 days. The biogas production and the others parameters were registered and estimated along the experimental running.



a) b)

Figure 1 Pilot reactor a) schematic configuration and b) view

2.2 Analytical procedure

Total and volatile solids (TS and VS) were measured as described in Standard Methods (APHA, 1998). The chemical oxygen demand (COD) was done in accordance with the open reflux method as described in Standard Methods (APHA, 1998). The samples for the analysis of soluble COD were prepared by filtration. The pH was measured with an ORION electrode. Gas production was determined with a glass syringe by the volume displacement. The biogas composition was measured with a Shimadzu 14B gas chromatograph fitted with Porapak Q packed column (0.32 mm ID and 2 m length) and a thermal conductivity detector (TCD). Helium was used as a carrier gas. Injector, oven and detector temperatures were 60ºC, 30ºC and 90ºC, respectively.

2.3 Inoculum

The inoculum used in experiments (sludge) was taken from an anaerobic digester in a wastewater treatment plant. After collection, the inoculum was adapted for several weeks, in a 10L reactor, with increasing substrate concentrations until achieving concentrations near the ones of the assays, and reaching a stable biogas production. During that period, the inoculum was fed with glucose and nutrient medium, prepared in accordance with Owen *et al*. (1979).

2.4 Substrates

The substrates used were fruits and vegetables manually sorted from municipal solid waste and grass. In order to get a more homogeneous mixture, fruits and vegetables were blended with a domestic blender. Table 1 shows the composition of the substrates used in this study.

Table 1. Characterization of substrates

Biodegradable Solid Wastes	TS (%)	VS (%)	pH
Vegetables and fruits	11	84	4.3
Grass	29	88	6.5

3 Results and Discussion

The average methane content in the biogas produced was 45 % and 70 % for R1 and R2 respectively (Figure 2). Assuming the heat potential of CH_4 as 35 880 $kJ.m^{-3}$, (Lastella *et al*., 2002) the heat potentials of biogas produced by reactors R1 and R2 were 16 146 and 25 116 $kJ.m^{-3}$. In accordance with Lastella *et al*. (2002) the biogas produced by reactor R2 represents a good potential energy recovery. The CH_4 percentage present in biogas produced by reactor R2 was comparable with values reported by Sosnowski *et al*. (2003) which achieved values greater than 60% and with those presented by Misi e Foster (2002) (between 60 and 64%). The value achieved by the reactor R1 it's similar only to the values reported by Gómez-Lahoz *et al*. (2007), which presents also lower methane production (0.100 $m^3CH_4.kg^{-1}VS$).

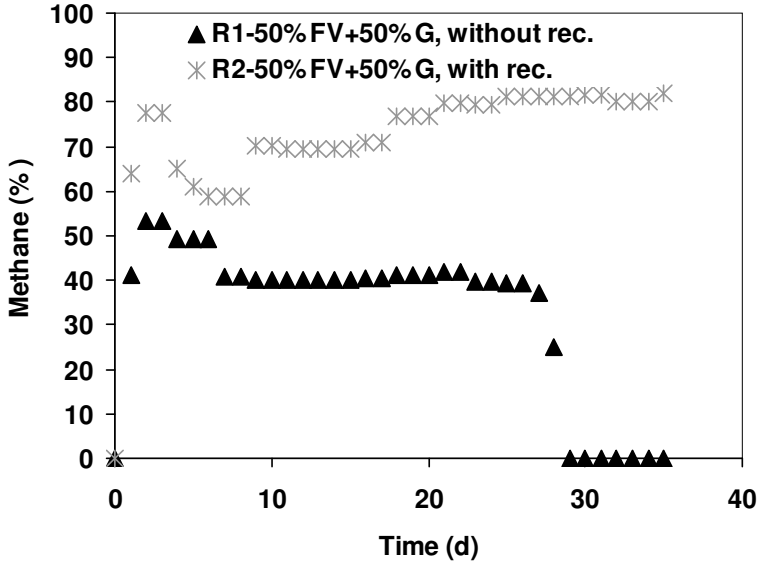


Figure 2. Methane content in biogas for reactor R1 e R2.

The methane production for both reactors is shown in Figure 3. Maximum specific methane production was achieved after 5 days for R1 and in after 15 days for R2. R2 presents a greater methane production (223.24 mL $CH_4.g^{-1}VS$) than R1 (41.54 mL $CH_4.g^{-1}VS$). The methane production achieved by reactor R2 was lower than the literature data on methane production from fruits and vegetables (0.409 – 0.529 $m^3CH_4.kg^{-1}VS$) and grass (0.342 – 0.420 $m^3CH_4.kg^{-1}VS$) (Gunaseelan, 1997). The value presented by reactor R1 it's only comparable with studies with very low methane production caused by a possible inhibition problem under anaerobic conditions (Agdag e Sponza, 2005, Gómez-Lahoz *et al.*, 2007). The methane volumetric productions achieved during the experiments were 0.2 and 1.1 m^3CH_4 per m^3 of reactor, for R1 and R2 respectively (Table 2). The problem with reactor R1 is possible caused by the poor contact between substrate and microorganisms.

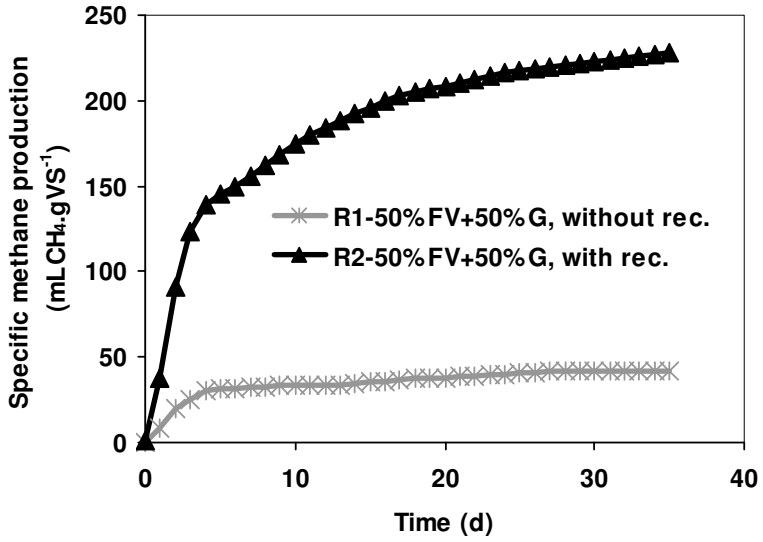

Figure 3. Specific methane production for reactor R1 and R2.

In both reactors, and during all the period of incubation, the pH (Table 2) of the digestion mixture did not need to be adjusted externally, because it was kept in the adequate range for anaerobic digestion 6.5 – 7.5 (Cecchi *et al.*, 2002), except for reactor R2 which presents a value of 7.65 at the initial stage, but quickly achieved values lower than 7.5 in the course of the digestion.

Table 2. pH and maximum specific methane production for R1 and R2

Reactor	pH initial	pH final	Methane volumetric production (m^3/m^3)	Maximum specific methane production (mL $CH_4.g^{-1}VS$)
R1	7.42	7.38	0.2	41.54
R2	7.65	7.49	1.1	223.24

The COD total (CODt) and soluble (CODs) were monitored during the experiments as an indicative parameter of organic matter removal. Both COD decreased rapidly in the first 25 days for reactor R1 and R2; reactor R2 presented COD values lower than R1, especially in CODs.

The rate methane production was calculated from the specific methane production (Table 3).

Table 3. Maximum rate methane production for reactor R1 and R2

Reactor	Time (d)	Maximum rate methane production (mL $CH_4.gVS^{-1}.d^{-1}$)
R1 (50%FV+50%G, without rec.)	2	10.87
R2 (50%FV+50%G, with rec.)	2	53.05

As was expected, the maximum methane rate production was much greater for reactor R2, clearly pointing to the importance of the recirculation in the overall methane production. Both reactors achieved the maximum value in 2 days.

4 Conclusions

The overall volume of methane produced was much higher in R2 than R1. This is probably due to the recirculation system which ensures a good homogenization of the reactor contents. Similar results were presented by Sponza and Agdag (2004).

The recirculation had a considerably positive effect in methane production, which corresponds to better energy recovery.

Further work will follow to determine the effect of different recirculation ratios on methane production, in order to maximize the energy recovery.

Keywords: Anaerobic digestion, ADM1, control, modeling, wastewater treatment.
Topic: Systematic methods and tools for managing the complexity — Process control & operations.

Abstract

In this work, different configurations of robust cascade controllers applied to anaerobic wastewater treatment are evaluated by simulation with ADM1 according to benchmark recommendations. Two of the controllers are already available in literature (Alvarez-Ramirez et al., 2002; Liu et al., 2004). In addition, a novel cascade controller approach is presented and compared with the others. This new approach, unlike the other two, is a multi-objective one. It considers two operational objectives in the same simple control structure: a.- the control on the effluent quality for fulfilling with the environmental regulations; and b.- the control on the maximum methane production rate. It requires two measured variables as inputs: the methane flow rate (Q_{CH4}) and the concentration of volatile fatty acids (VFA) expressed as acetic acid. The advantages and disadvantages of the controllers are discussed in detail.

1 Introduction

Anaerobic digestion processes consist of a set of conversions of organic matter into methane and carbon dioxide, occurring in absence of oxygen (Lettinga, 1995). Most of the organic effluents and wastes coming from industrial, municipal or agricultural activities can be effectively processed by anaerobic wastewater treatment (AWT) plants. The following are some of the reasons why AWT has gained importance in the last years (van Lier et al., 2001): a.- use of methane as an energy source; b.- the low production of sludge; and c.- its ability to treating wastewater with medium to high organic loads. However, AWT has classically been regarded as a difficult process to be controlled and managed. Different disturbances can affect the performance of an anaerobic reactor and the recovery of the normal conditions can be long and expensive. Therefore, the selection of an accurately control system could give important advantages in the management of these reactors helping to minimize the operational cost and maintain the plant under safe conditions.

The range of possible control systems is quite broad, and its application has been quite limited. In this sense, it is necessary to have a standard tool that allows different controllers performance to be compared. Several researchers have been working to standardize the use of models in wastewater treatment processes (Copp, 2002; Vrecko et al., 2006; Jeppsson et al., 2007). Particularly, with regard to anaerobic digestion models, Rosen et al. (2006) discussed about a number of research works with the Anaerobic Digestion Model Nº1 (ADM1 - Batstone et al., 2002) during COST/IWA Benchmark Simulation Model (BSM2). The BSM2 is a control benchmark for plant wide modeling. Complex models such as ADM1 are a good

* Corresponding author. Tel +34 981-563100 Ext.: 16742. E-mail:carlos.garcia.dieguez@usc.es

choice to evaluate controllers competitively, and develop operational strategies (Batstone & Steyer, 2007).

In this work, ADM1 was used, according to benchmark recommendations, for comparing the performance of three different configurations of robust cascade controllers for anaerobic wastewater treatment (AWT) of vinasses.

2 Model description and problem statement

2.1. *IWA Anaerobic Digestion Model no. 1 (ADM1) and AWT plant*

ADM1 (Batstone et al., 2002) is a complex model of the multistep anaerobic process transformations. This tool is adequate for predictions of enough accuracy to be useful in process development, optimization and control. ADM1 incorporates processes such as hydrolysis of particulates, acidogenesis, acetogenesis and methanogenesis, and it includes 26 dynamic state concentration variables, 19 biochemical kinetic processes, 3 gas-liquid mass transfer kinetic processes, and 8 implicit algebraic variables per liquid vessel.

A modified version of ADM1 (Batstone et al., 2002) incorporating ethanol degradation pathways and calibrated for a heavily instrumented USBF reactor of 1.15 m^3 (Ruiz-Filippi et al., 2004) was used. In this ADM1 version, an additional group of ethanol degraders was included as well as a new state variable for ethanol concentration. The extension for ethanol not only considers the hydrogen and acetate pathways but also takes into account other pathways of interest in controller design as volatile fatty acids (VFA) pathways (in particular for propionate and butyrate) by means of the stoichiometry. Thus, VFA evolution, including responses against overloads or transitions between steady states, is adequately predicted.

2.2. *New controller approach*

The block diagram describing the structure of the new cascade controller approach proposed here is shown in Figure 1. Basically, this control system consists of two loops in cascade. The inner loop (Slave Controller) uses the methane production rate as state variable as well as the output of the Master Controller as reference. The outer loop (Master Controller) compares the measured VFA concentration with the VFA set-point as input error.

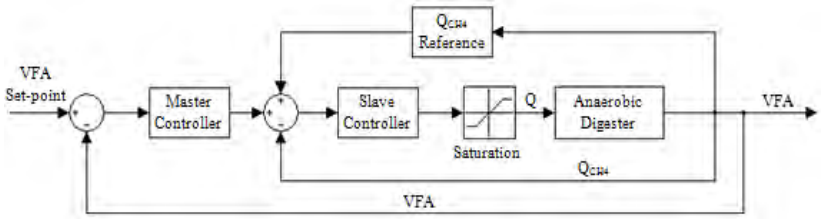

Figure 1. Block diagram of the new approach cascade controller. Note that Q_{CH4} reference signal provides the set-point to the inner control loop.

The parameters of the new approach had been optimized, and the applied values are given in Table 1, where K_c, K_I and K_d are the proportional gain, the integral factor and the derivative factor for each PID controller, respectively.

Parameters	Slave	Master
K_c	0.0172	0.38
K_I	$7.2 \cdot 10^{-7}$	0
K_d	0.0006	0

Table 1. Parameters of the new cascade controller approach.

The methane reference signal (Q_{CH4} reference) was established as a function of the chemical oxygen demand in the influent (COD_{in}) through an empirical correlation. This empirical correlation is different for each control objective. In this case, it was obtained by means of simulations. In the case of cascade controller, the simulations consist of optimizing in pseudo steady-state the methane production rate for different concentrations of COD_{in} that accomplished the requirement of spillage (150 mg Ac/l). For the inner loop controller, the simulation consists of obtaining the maximum methane production rate vs. COD_{in}.

The feed flow rate (Q) is constrained by a saturation function (according to physical restrictions on manipulated variable). The minimum feed flow rate is zero and the maximum feed flow rate was established using the criterion of minimum hydraulic retention time (HRT) of 9 hours for preventing undesired wash-out of biomass. Furthermore, the speed of variation (increase or decrease) of the feed flow rate (ΔQ) was limited to 0.5 l/h each 15 minutes.

3 Controllers comparison

The three types of cascade controllers were properly tuned as a previous step to the comparative evaluation of their performance. For this task, a sequential quadratic programming (SQP) combined with ethanol modified ADM1 for parameter optimization was required for the new cascade controller approach. The time required for this optimization was approximately 12 min in an Intel Core Duo E6550 233GHz and 2 Gb of RAM running Matlab® 7.0 (R14). In the other cases, an extensive manual tuning from the original parameters was employed. The parameters of the new controller were already shown in Table 1. The parameters used for the Liu controller were K_{pm} = 33 (master controller proportional gain), K_{ps} = 2 (slave controller proportional gain), D_{min} = -0.3 (lower limit for D, which represents the difference between the methane flow rate and its set-point) and D_{max} = 0.1 (upper limit for D in the supervisor system), being those for the Alvarez-Ramirez et al. controller K_{Im} = 3 (integral factor of the master controller) and K_{ps} = 0.5 (slave controller proportional gain).

3.1. *Alvarez-Ramirez et al. controller versus new approach*

The controller of Alvarez-Ramirez et al. (2002) only controls the outlet concentration of VFA and it was not designed to achieve automatic restart-up in a wastewater treatment system. On the other hand, one of the main advantages of the new controller approach is that it offers total control over an automatic restart-up of the system. The response of both controllers to a severe organic overload by a 50% of increase of input COD from 10 g COD/l to 15 g COD/l, is shown in Figure 2. Considering a quality effluent control criterion, the new approach cascade controller had a greater speed of response against organic overload perturbations than the Alvarez-Ramirez et al. controller. The new controller approach can stabilize the treatment system, in a very reasonable time, taking into account the magnitude of the perturbation and the low error permitted for the controlled variable. Thus, the controller of Alvarez-Ramirez et al. presents more oscillations, having a tendency to destabilize if other perturbations take place at the same time. This fact can be visualized through the error on the controlled variable (VFAs).

The variables selected for the Alvarez-Ramirez et al. controller do not take advantage of the difference between the dynamics of the liquid and gas phases for improving its response. Besides, the measurement times for this controller are very low compared with the response times of the control variables (VFAs and COD). In the work of Alvarez et al. large oscillations, considering the magnitude of the perturbations applied can be observed.

Therefore, if the treatment system suffers important concentration disturbances in the influent, this controller could not be the most appropriate. In addition, the best option for on-line monitoring COD and VFAs would be to use infra-red spectrometry. This choice is more

expensive than on-line monitoring of VFAs by means of a titrimetric smart sensor (Molina et al. 2008).

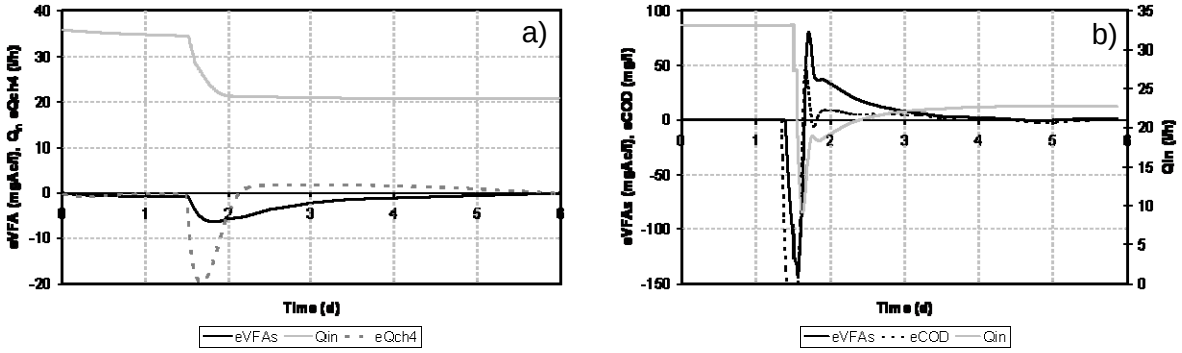

Figure 2.Comparison during a severe organic overload (from 10 to 15 g COD/l): a) New controller approach, b) Alvarez-Ramirez et al. controller.

3.2. *Liu et al. controller versus new approach*

The Liu et al. (2004) controller, unlike that of Alvarez-Ramirez et al. (2002), does not take into account the effluent quality, because its objective is the maximization of methane production. In this regard, it has been compared with the new controller approach presented here. The new controller approach can lead to the system up to the maximum treatment capacity, if the external control loop is disconnected, and set up the methane reference signal that corresponds with this objective. The results obtained with both controllers during an automatic restart-up experiment (COD_{in} constant and equal to 10 g COD/m^3) are shown in Figure 3. According to Molina et al. (2007), a treatment capacity equal to 12 kg COD/m^3·d was considered for the USBF reactor.

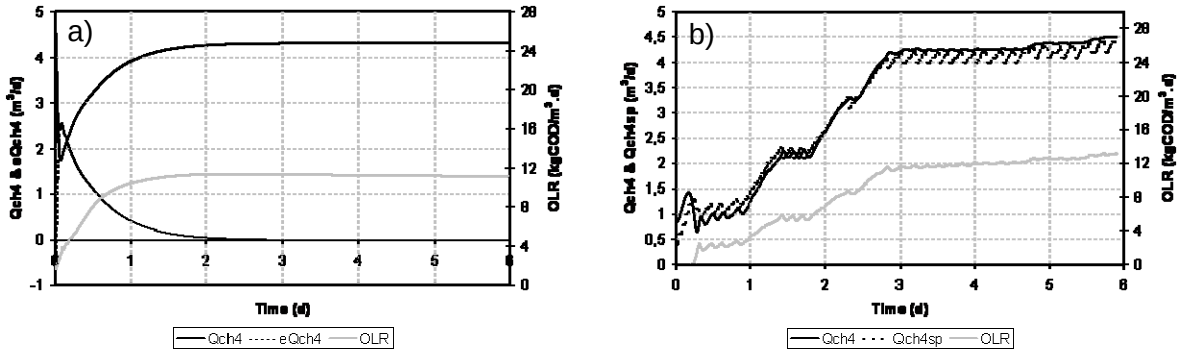

Figure 3. Restart-up of the USBF reactor using the new cascade controller approach and the Liu et al. controller: a) New cascade controller approach; b) Liu et al. controller.

In terms of maximum methane production rate criterion, the Liu et al. controller and the new controller approach presented a reasonably similar performance. However, the new approach reaches an organic loading rate (OLR) equivalent to the maximum production capacity of methane earlier than Liu et al. controller. Furthermore, the Liu et al. controller does not take into account the effluent quality. Besides, this controller uses the pH in the inner-loop, generating a series of difficulties in its industrial scale application: 1. The location of pH sensor that can be able to capture the appropriate information; 2. A pH sensor for an industrial application does not have enough resolution for a properly function of the control system; 3. The simulations reveal that set-point reached by the controller is highly dependent

of the alkalinity added and the selected parameters. This controller required a great consumption of bicarbonate for fulfilling alkalinity needs and maintaining the reactor in a stable operation. These seem to be the main drawbacks for its application at industrial scale. On the other hand, the new controller approach requires to be tested in closed loop experiments at pilot scale to confirm the hypothesis. The main advantage of Liu et al. controller is that already uses available variables in all anaerobic industrial plants, while the new approach requires the use of a relatively low-cost sensor for measuring VFAs, which is already available on the market (Molina et al, 2008).

4 Discussion

The difference between the evaluated controllers owes principally to the different variables used to define the control strategy or the control law. The selection of the properly inner-loop variable determines the performance of cascade structures, as the inaccurately cancellation of the error in the inner-loop affects the cascade efficiency. An internal suitable variable must fulfill with a series of criteria or requirements. The most relevant ones are listed in Table 2 together with the variables, indicating a qualitative degree of fulfillment for the development of a controller in cascade for an AWT plant.

Criterion	Q_{CH4}	$\%CH_4$	Q_{gas}	$\%CO_2$	**CO**	H_2
Secondary variable is available	A	A	Y	O	A	A
Indicates a key disturbance	Y	O	Y	N	N	Y
Causal relationship with the controlled variable	Y	N	Y	N	N	N
Secondary dynamic faster than primary	Y	Y	Y	Y	Y	Y

Table 2. Evaluation criteria for inner-loop variables suitability. (Y-Yes; N-No or Not appreciable; N/A- Not applicable; A-Advanced instrumentation; O- In occasions; S-Similar).

As it can be seen in Table 1, the methane flow rate (Q_{CH4}) and the biogas flow rate (Q_{gas}) were the best inner-loop variables. The liquid phase variables are supposed to present higher response times than the gas phase variables. Therefore, bear in mind this criterion an inner control loop with a secondary variable from the liquid phase does not seem to be the most appropriate. In addition, with the same criterion, a combination between variables in the gas and liquid phases will allow the controller to take advantage of the difference between the dynamic of both phases. Thus, the best choice seems to be the use of a variable of the liquid phase (slow response) as control variable in the external loop, and a variable of the gas phase (fast response) as control variable in the inner loop.

In this way, Alvarez-Ramirez et al. controller uses two variables of the liquid phase (VFA and COD_{out}) as process variables, which would delay the response of this control system. The Liu et al. controller uses pH, as state variable. This variable does not enable a fast and appropriate control action unless a fine control on the addition of alkalinity was also available, especially at a full-scale reactor.

5 Conclusions

In this paper, the performance of a new controller in cascade for anaerobic wastewater treatment plants was compared with two other controllers in cascade already available in literature (Alvarez et al., 2002 and Liu et al., 2004) by means of simulations. The model used for this work was the Anaerobic Digestion Model N°1 (ADM1), implemented according to the BSM2. This tool has allowed the performance of these controllers to be tested under the same conditions of operation, obtaining as main conclusion that the selection of the inner-loop control variable affect the performance of the controllers studied here. The promising

new controller requires a further and extensive validation in closed-loop for checking its suitability working in pilot and industrial scale systems.

Keywords: water, diesel fuel, emulsion, electrocoagulation, modeling
Topic: Sustainable process – product development through green chemistry

Abstract

Electrocoagulation (EC) is one of the promising contaminated water treatments, where impurities are removed by coagulation and flotation, while coagulant is added *in situ* by electrochemical oxidation of the suitable anode material. EC is possible alternative to the metal salts or polymers and polyelectrolyte addition, for the stable emulsion breaking, adsorption, as well as the metal, colloids and soluble inorganic impurities removing.

In this work, efficiency of electrocoagulation process for hydrocarbon removing from the water emulsion was investigated. As model solution, emulsion of diesel fuel in distillate water with addition of sorbitan monooleate as the emulsifier was used. Process was conducted in the batch reactor with the aluminum electrodes, with addition of the NaCl for the increase of electrical conductivity of the emulsion. Inlet parameters were NaCl and diesel fuel concentrations in emulsion, current density and reaction time. Outlet parameters were total organic carbon (TOC), filtrate volume and mass loss of the anode material. Experiments were conducted in two sets, each with 16 treatments, settled by two level factorial design (TLFD) method. Quantitative influence of each factor, inlet parameters and their interactions on the main responses were calculated, and presented with mathematical correlations.

Obtained results indicated very high efficiency of the electrocoagulation process, for the hydrocarbon removal from water emulsion, ranging from 98.9 to 99.5 %, calculated in respect to the total organic carbon content in water, while current efficiency was in the range from 17 to 78 %. Water phase after the EC process was odorless, tasteless and colorless. As expected, it is proven that the current efficiency is increasing with increase of the electric conductivity of the emulsion and with decrease of the current density. High TOC removal was obtained even for the short periods of reaction time (5 minutes), meaning that higher current efficiencies are possible with lower current densities at prolonged reaction times.

1. Introduction

Petroleum and its derivates are one of the most used substances in the world today. Generally, they are very complex mixtures of various compounds, mostly hydrocarbons. These compounds are usually categorized as alkanes, naphtenes and aromatic hydrocarbons. Motor fuels, lubricants and other oil derivates contain these groups of hydrocarbons in different ratios. Most hydrocarbon compounds are not soluble in water. Nevertheless, if the spill out occurs, there is a danger of emulsion formation. There is also a danger of gradual hydrocarbon dissolution from sediments that are formed because of the oil spill. One of the nature purging mechanisms of the contaminated water is hydrocarbon compounds sedimentation, i.e. deposition to the bottom; cca 10 to 30 mas.% of the total amount is deposited, depending on the conditions that dominate at that area and water depth[1].

Today, varieties of the water purification methods that include biological and physico-chemical treatments are well known and available. New methods that do not include different chemicals and reagents addition will become very popular in the near future. Some of those methods are electrocoagulation, electroflotation, electrodecantation[2]. Coagulation is phenomena were charged particles in colloid suspension are neutralized by negatively charged ions, followed by agglomeration and then sedimentation. Coagulant is added in the form of an appropriate chemical substance. In electrocoagulation coagulant is added in situ by electrochemical oxidation, i.e. appropriate anode material dissolving. This process is carried out in three successive phases: the first phase is coagulant formation by anode oxidation, followed by contamination and suspension destability and emulsion breaking. The last phase is an unstable phase aggregation and flocs formation, followed by electro flotation / electro precipitation[3]. The best anode materials are iron and aluminum because they have high charge ions. Aluminum ions are especially unstable; with release from the electrode surface they react with hydroxyl ions and are adsorbed on the colloid particle surface. With electrochemically dissolution of the anode (aluminum electrode) cation monomer species like Al^{3+} and $Al(OH)^{2+}$ are produced under low pH values, that with the rise of the pH values become $Al(OH)_3$ and finally polymerized $Al_n(OH)_{3n}$ by following reaction pathway[4]:

$$Al \rightarrow Al^{3+}(aq) + 3e^- \qquad E^o = -1.66\ V \qquad (1)$$

$$Al^{3+}(aq) + 3H_2O \rightarrow Al(OH)_3 + 3H^+ \qquad (2)$$

$$nAl(OH)_3 \rightarrow Al_n(OH)_{3n} \qquad (3)$$

Simultaneously, hydrogen is forming on cathode by following reaction pathway:

$$2H_2O_{(l)} + 2e^- \rightarrow H_2(g) + 2OH^-(aq) \qquad E^o = -0{,}83\ V \qquad (4)$$

At the last few years electrocoagulation has proven itself as an effective method of treatment and purification for various contaminated waters, such as waters contaminated with mineral and vegetable oils, organic dyes, as well as waters from metallurgic, paper and leather industry, etc[4]. In this paper effect of current density and reaction time, in electrocoagulation process, on the diesel /water emulsion breaking is investigated. Efficiency of the process is monitored through total organic carbon (TOC), filtrate volume and mass loss of the anode material[5].

2. Experimental

Materials

Emulsions used in this research were prepared by mixing appropriate masses of diesel and redistilled water with addition of the NaCl for the electrical conductivity increase. Non-ionic surfactant, sorbitan monolaurate, Span 80 having an 4.3 HLB (hydrophilelipophile balance) (Fluka), was used as the stabilising agent at concentration of 0.5 wt.%. A sample of commercial diesel was obtained from INA d.d. Croatian Oil Company. The main properties of

the diesel are listed in Table 1.

Table 1. Physical and chemical properties of the diesel fuel

Property	Value
Cetane number	51.0
Density at 15°C (kg m^{-3})	845.0
Total sulfur (mg kg^{-1})	50
Polycyclic aromatic hydrocarbons (wt.%)	11
Kinetic viscosity at 40°C (mm^2 s^{-1})	2.0
End of distillation (°C)	360

Process and methods

Emulsions were prepared in vessel with variable speed-controlled impeller. Redistilled water and Span 80 were mixed at 400 rpm for a mixing time of 1h. Thereafter, diesel and NaCl were added to the emulsion and continued with mixing for 1 hour, until stabile emulsion was formed. Electrocoagulation process was conducted in batch reactor, in glass cell with aluminum electrodes (anode and cathode). The electrocoagulation apparatus and electric circle scheme is presented in Fig 1. The anode and the cathode surface were 50 cm^2 each and the distance between them was 5 cm. All measurements were conducted under constant stirring rate (400 rpm) and controlled temperature (25.0 °C). Effect of current density and time on the emulsion separation efficiency was investigated. EC efficiency was monitored through measurements of electrode mass loss, filtrate volume and TOC values in the separated aqueous phase. TOC values of the samples were measured using Total Organic Analyzer (Shimadzu, TOC-V_{CPN}).

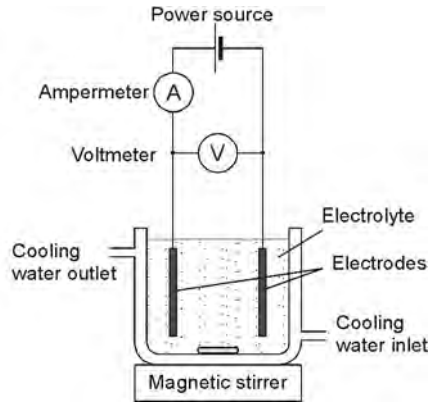

Figure 1. The electrocoagulation apparatus and electric circle scheme

Hydrocarbon separation efficiency from aqueous phase is given by equation:

$$U_{TOC} / \% = (TOC / TOC_0) \times 100 \quad (5)$$

Current efficiency , η_{el}, for the production of dissolved Al^{3+} is given by equation:

$$\eta_{el} / \% = (m_{teor} / m_{exp}) \times 100 \quad (6)$$

where m_{exp} is the weight loss of the aluminium electrodes during the experiment and m_{teor} the theoretical amount of aluminium consumed according to Faraday's law given by equation:

$$m_{teor} / g = [I (A) \times t (s) \times M (g\ mol^{-1})] / [z \times F (A\ s\ mol^{-1})] \quad (7)$$

where *I* (A) is the current density, *t* (s) the experiment duration, *M* (g mol^{-1}) the molar mass of aluminium and *F* (A s mol^{-1}) the Faraday constant.

Statistical study

A statistical study was performed by applying a 2^4 full factorial design[6]. According to this design, 32 runs were made during which 4 parameters: diesel fuel concentration (X_1), NaCl concentration (X_2), current density (X_3) and time (X_4) were varied over the 2 levels. The levels of the parameters with their actual and coded factors are presented in Tab 2. The coded values of the two levels were designed so 1 represents the higher value and 0 the lower value. Experimental runs were carried out randomly, with one replicate of each run. Described design was carried out to determine which parameter have important effect on response and possible interactions between parameters, which couldn't be seen by variation of only one parameter, leaving others constant. The statistical calculations were performed using software tool Design-Expert (State Ease, Inc.).

Table 2. Designed levels of the parameters with their actual and coded factors

Parameter	Value	
	Lower level (0)	Higher level (1)
X_1: Diesel fuel concentration, *c* (DF) [mas. %]	4	15
X_2: NaCl concentration, *c* (NaCl) [mas. %]	1	2.5
X_3: Current density, *I* [A]	0.5	1
X_4: Time, *t* [min]	5	30

3. Results and discussion

2^4 full factorial design with coded factors and experimentally obtained data is presented in Tab. 3. Determination of the most significant influences on the EC process response was made by half normal probability of main effects and their interaction analysis. Chosen significant effects were additionally validated with F-test, which value below 0.05 implied that effect is significant and can be implemented into the mathematical model of the process. With multiple regression analysis of the obtained data, performed with Design-Expert software, mathematical description of EC batch process was expressed with statistical model (Eq. 8).

$$y = \beta_0 + \beta_A X_1 + \beta_B X_2 + \beta_C X_3 + \beta_D X_4 + \beta_{AB} X_1X_2 + \beta_{AC} X_1X_3 + \beta_{AD} X_1X_4 + \beta_{BC} X_2X_3 + \beta_{BD} X_2X_4 + \beta_{CD} X_3X_4 + \beta_{ABC} X_1X_2X_3 + \beta_{ACD} X_1X_3X_4 + \beta_{ABD} X_1X_2X_4 + \beta_{BCD} X_2X_3X_4 + \beta_{ABCD} X_1X_2X_3X_4 \quad (8)$$

where; y is the response, X_1, X_2, X_3 and X_4 are variables, β_0 is the constant coefficient, β_j´s, β_{jj}´s and, β_{jjj}´s are interaction coefficients. The experimental results were evaluated and coefficients of main variables for investigated responses obtained with the least square method and are given in the Tab. 4.

Coefficients values are representing impact of that factor, i.e. interaction, on the response of the process. It can be seen from the Tab. 4 that the most significant factor for TOC and electrode mass loss was time (X_4) with constant coefficients of 14.31 and 0.11. For the filtrate volume most significant factor was inlet diesel concentration (X_1) with constant coefficient of 0.66. The most significant interaction for TOC and filtrate volume was between inlet diesel concentration in emulsion and current density with interaction coefficient of 8.83 and 0.21. For electrode mass loss interaction between NaCl concentration and time, and current density and time, were almost equal and were 0.02 and 0.03.

Table 3. 2^4 full factorial design and results of experiments.

With mathematical model it is possible to predict most important responses of the EC process in the range of the chosen inlet parameters values. In Figs. 2a-c three-dimensional dependences of TOC values vs. inlet diesel concentration, NaCl concentration, current density and time for EC separation of diesel emulsion, are presented in the form of response surfaces. In this way it is easy to see influence of parameters and their interactions on chosen response. On Figs. 2a and 2b it can be seen that response surfaces are curved

which means that influences of X_1X_3 and X_1X_4 on TOC are significant. Response surface on Fig. 2c is almost plane, meaning that X_3X_4 interaction on TOC is less significant.

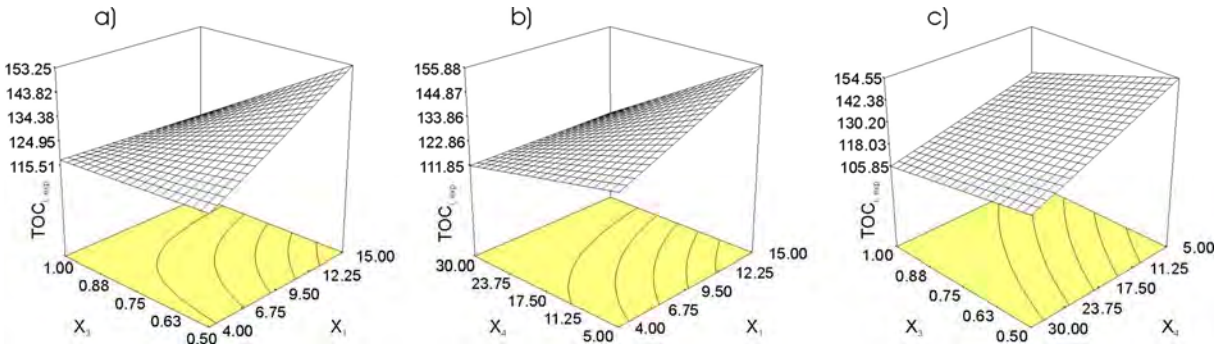

Figure 2. Response surfaces and contour plots of TOC values for EC process

From presented TOC dependences, it can be seen that all experimentally obtained TOC values after EC process are very small. Slightly higher TOC values were obtained for higher diesel fuel concentrations, while lower TOC values were obtained with increased current density and longer reaction time. Still, these differences are very small for given parameters in researched range of values. With current density increase, reaction time for diesel separation is decreasing, same as current efficiency for anode reaction of aluminum dissolution. As hydrocarbon separation efficiency do not change significantly with current density and it is easy to control kinetics and electrical energy consumption of the EC process.

4. Conclusion

With electrocoagulation process successful separation of diesel from aqueous emulsion was achieved, with efficiencies higher than 99%. Obtained filtrate was colorless, odorless and clear, with sludge that could be easily separate from the solution. EC process was empirically described with suitable mathematical model, in which experimentally obtained TOC value do not differ much from values predicted by model.

Obtained results showed a great potential of the EC process as a treatment method for waters contaminated with oil. EC process doesn't require use of any chemicals, allow separation of smallest colloid particles and it is easy to control with low maintenance of the equipment. Limitations of EC process are required high electrical conductivity of the emulsion and relatively short lifetime of the sacrificed anode.

Keywords: Coagulation, Adsorption, Reactive dyes, Aluminum chloride, Reactivation
Topic: Sustainable process-product development through green chemistry.

Abstract

The aim of the present study was to investigate the removal of reactive dyes, Black 5 and Orange 16, through a combined coagulation/adsorption process on activated carbon. A coconut-based powdered activated carbon was used as an adsorbent and aluminum chloride was chosen as the coagulant. In order to obtain the best removal conditions for these dyes, the influence of the following parameters were investigated: coagulant dosage, aqueous solution pH, addition of sodium chloride and the application of increased temperature plus sodium chloride. Adsorption results for the reactive dyes were analyzed by Langmuir and Freundlich isotherm models and showed good correlation. The presence of sodium chloride in the mixture resulted in significant adsorption improvement. The influence of increased temperature plus sodium chloride on the dye removal from aqueous solution showed the feasibility of adsorption and its endothermic nature. Through the reactivation experiments it was verified that the adsorbent can be reused three times, consecutively, after the first adsorption with the virgin carbon. For the final evaluation of the effluent, obtained after the coagulation and adsorption process, acute toxicity tests were carried out with *Daphnia magn*a, and the results obtained showed that the final effluent was not toxic. The combined coagulation/adsorption process was found to be an excellent option for the removal of reactive dyes.

1 Introduction

The removal of dyes from industrial effluents is an extremely complex problem due to the different dye structures and properties and, more importantly, to the majority having a non biodegradable nature (Jain *et al*., 2002). However, many physical, chemical and biological treatment processes have been used for dye removal in order to achieve a better quality effluent. The choice of one or the combination of two or more techniques is dependent on the potential of each technique and on the mechanisms involved in the reduction of the contaminant of interest (Papic *et al.,* 2004, Chakraborty *et al*., 2005, Solmaz *et al*., 2007).

The adsorption of organic compounds on activated carbon is one of the most important technologies used for the treatment of industrial effluents. This adsorbent has a high surface area and a variety of functional groups at its surface (Duan *et al*., 2002, Guilarduci *et al*., 2006).

Many of the materials present in a textile effluent cannot be removed by simple physical separation. In these cases, when the treatment is unsatisfactory, other processes are necessary (Tomaszewska *et al*., 2004).

2 Materials

In this study, a synthetic wastewater was prepared to simulate the characteristics found in textile effluents, with the objective of controlling the effluent composition during the

experimental investigation. Initially, a concentrated solution (2000 mg/L) was prepared from the mixture of the quantities of dyes established and distilled water. All the other solutions used experimentally were obtained through careful dilution of this solution. Next, the pH of the diluted solutions was adjusted with a pH meter to the levels selected with addition of NaOH and 0.1 M HCl.

The experiments were carried out with two non-hydrolyzed reactive dyes, Black 5 (λ =598 nm) and Orange 16 (λ =491 nm). A coconut-based powdered activated carbon with a surface area of 734 m^2/g was used as the adsorbent.

Aluminum chloride ($AlCl_3.6H_2O$ – 99.5 % purity) was used as the coagulant having a molecular mass of 241.43 g/mol. The dye concentration was evaluated using spectrophotometry (Shimadzu Model: UV-1240) at the wave of maximum absorbance.

3 Methods

The chemical coagulation experiments were carried out in static reactors (*Jar test*) using 1 L of solution in each reactor at a temperature of 25 ± 1ºC. The samples were allowed to settle for a period of 1h after 1 min 40 s of rapid mixing (175 rpm) and 10 min of slow mixing (15 rpm). At the end of the sedimentation period aliquots were removed at 2 cm below the surface of the effluent for the determination of the residual color. The optimum dosage of coagulant and pH of the mixture in the coagulation process were determined.

The experimental adsorption tests were carried out with the pre-treated synthetic effluent using the activated carbon adsorbent. Kinetic and equilibrium data were determined and the influence of pH, salt addition (NaCl) and increased temperature plus salt addition on the dye removal using the adsorption process was investigated.

In the preparation of the reactivated carbon, the material precursors of successive adsorptions were dried in an oven for 4 hours and then prepared for carbonization before subsequent chemical activation with acetic acid 1M. After the pore activation stage, the activated carbon was dried in an oven at 110ºC for a period of 4 hours.

The experimental data on the variation of the solute concentration adsorbed in the solid phase (adsorbent) as a function of the equilibrium concentration in the fluid phase were adjusted using the Langmuir and Freundlich models.

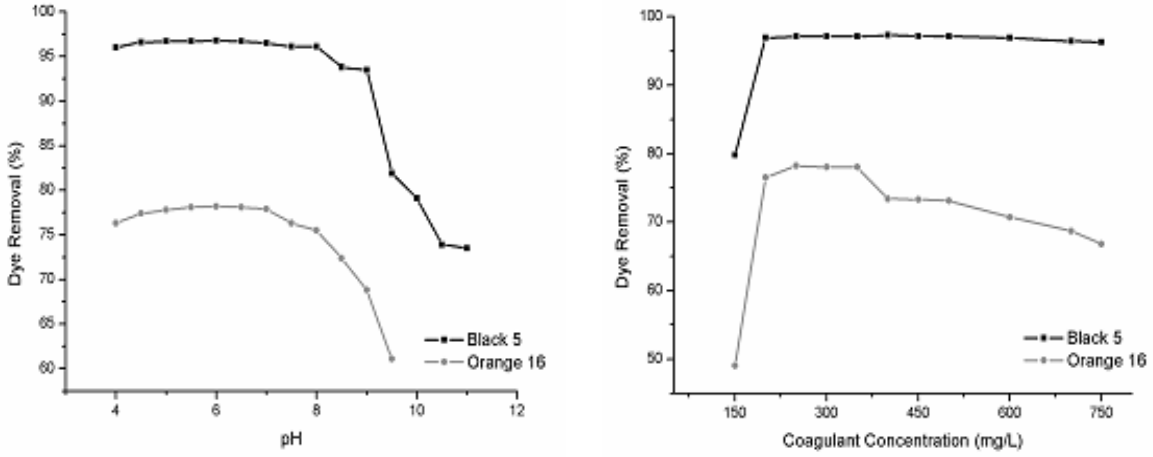
The tests with the bioindicator *Daphnia magna* were carried out according to the ABNT standard (1993), and results were expressed as the Factor of Dilution (FD). The FD represents the first of a series of sample dilutions at which acute toxic effects to the test organism are no longer observed (FATMA, 2002). The time for which the test organism was exposed to the effluent was 48 hours, after which the number of immobile organisms was observed and recorded. According to the legislation (article n°017/02 of FATMA), the maximum dilution factor for an effluent of textile origin is two (FATMA, 2002).

4 Results

4.1 Coagulation Tests: Optimum pH and Coagulant Dosage

In the Jar Test experiments the pH values were varied from 4 to 12 in order to obtain the most favorable pH for the color removal. The best results were obtained in the acid region of pH 4 to 7, the greatest removal percentage being obtained at pH 6 for the two dyes under study, as shown in Figure 1a. Similar results were reported by Kim *et al*. (2004) for a chemical treatment by coagulation with removals of 71.7% at pH 6 and 93.9% at pH 5, for dyes Blue 106 and Yellow 54, respectively. The subsequent experiments were thus carried out at the pre-determined pH value of 6, varying the coagulant dosage from 150 mg/L to 750 mg/L. The dye removal as a function of the coagulant concentration is shown in Figure 1b. The removal efficiency for both dyes increased with an increase in the coagulant dosage up to a certain dosage and then remained constant for the dye Black 5 and reduced gradually for Orange 16. The maximum efficiency of color removal was for a coagulant dosage of 200

mg/L, for Black 5 and for Orange 16 the maximum removal was obtained with 250 mg/L of coagulant.



(a) (b)

Figure 1: Optimization of the parameters in the pre-treatment stage for reactive dye removal: (a) pH (b) coagulant concentration

4.2 Influence of pH on the adsorption process

The influence of pH on the dye adsorption on activated carbon was analyzed through data on the adsorption kinetics and isotherms, in order to select the most favorable pH for the adsorption of the dye by the carbon. Through the kinetic experiments it was verified that the time to reach equilibrium was approximately 380 minutes, for all the pH values investigated. The kinetics data allowed the construction of the adsorption isotherms, shown in Figure 2, for the pH values of 2, 3, 4 and 7, respectively. The maximum adsorption capacity, as shown in Figure 2, increased from 16.6 to 19 mg/g with an increase in the pH from 2 to 3. However, it decreased to 5.8 mg/g with a pH of pH 7. Thus, it can be concluded that pH 3 is the optimum pH for the color removal process.

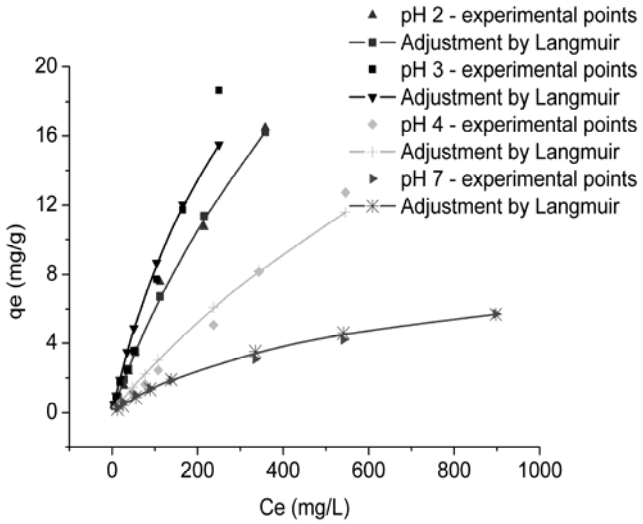


Figure 2: Langmuir isotherms for the different pH values.

4.3 Influence of the Addition of Sodium Chloride

Identical solutions were used for the kinetic experiments, varying only the values of sodium chloride between 0, 1, 3, 6 and 10% (by mass). Equilibrium was reached in approximately

340 minutes for solutions containing salt. In the case of solutions without salt, the adsorption was a little slower and equilibrium was reached in 380 minutes for both dyes. The values for the Langmuir parameters ($q_{máx}$) were calculated from the isotherms for addition of different quantities of sodium chloride to Black 5 and Orange 16. It was found that the maximum adsorption capacity increased from 19 to 87.7 mg/g with an increase in the quantity of sodium chloride from 0% to 6%. However, it decreased to 43.7 mg/g with an increase in the quantity of sodium chloride to 10%. In relation to the dye Orange 16, it was verified that the adsorption capacity increases from 27.5 to 74.1 mg/g with an increase in the quantity of sodium chloride from 0% to 1%.

Thus, 6 and 1% of sodium chloride appear to be the optimum quantities to improve the color removal process for the dyes Black 5 and Orange 16, respectively.

According to Guelli U. Souza *et al*. (2008), the presence of salt promotes the adsorption of positive charges when compared with experiments in its absence. This may indicate that the salt cations neutralize the negative charge on the surface of the carbon, increasing the adsorption of molecules.

4.4 Influence of increased temperature plus Salt Addition

Increased temperature combined with sodium chloride addition (6% of the aqueous solution mass for the dye Black 5 and 1% for Orange 16) was found to improve the adsorption process. The time required for equilibrium to be reached was approximately 300 minutes, for the two dyes under study. On analyzing the Langmuir parameters, it was verified that the maximum adsorption capacity increased with the increase in the temperature from 87.7 mg/g at 25ºC to 95 mg/g at 70°C for the dye Black 5, and from 73.5 mg/g at 25ºC to 99.7 mg/g at 70°C, for Orange 16. These results indicate the endothermic behavior of this adsorption process. This result is consistent with that reported by Senthilkumaar *et al*. (2006), where the capacity for adsorption of the dye Crystal Violet increased by 40% when the temperature was increased from 28 to 48 °C.

4.5 Reactivated Carbon Tests

Through the reactivation experiments, it was found that the adsorbent can be reused three times, consecutively, after the first adsorption with the virgin carbon. The time for the solutions with reactivated adsorbent to reach equilibrium was approximately 340 min; in the case of the solution with the virgin carbon, the equilibrium adsorption was reached in 300 min. Figure 3 shows the Langmuir isotherms obtained for the cases of adsorption with the virgin carbon and its respective reactivations. It is possible to verify in Figure 3 that the values for the maximum adsorption capacity, q_m, were 95, 80, 44.4 and 28 mg/g for the virgin carbon and the first, second and third reactivations, respectively.

For the four pH values studied, R_L varies between 0.206 and 0.976 ($0 < R_L < 1$), and the Freundlich coefficient, n, varies between 0.671 and 0.939 ($0 < n < 1$), confirming conditions favorable for adsorption.

For the cases of sodium chloride addition, R_L varied between 0.283 and 0.976 ($0 < R_L < 1$), and the Freundlich coefficient, n, between 0.756 and 0.918 ($0 < n < 1$).

For the three reactivation cases, R_L varied between 0.292 and 0.940 ($0 < R_L < 1$), and the Freundlich coefficient, n, between 0.836 and 0.867, confirming conditions favorable for adsorption ($0 < n < 1$).

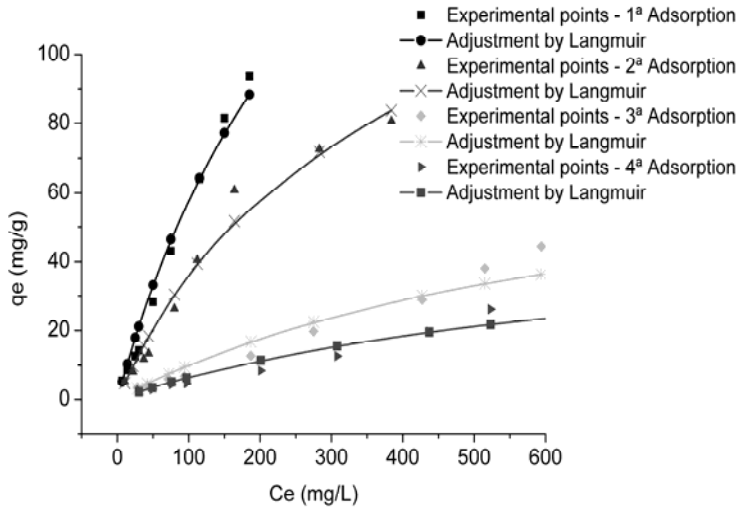

Figure 3: Langmuir isotherms for the adsorption with the virgin carbon and three reactivations.

4.6 Acute Toxicity Tests

The results with the bioindicator *Daphnia magna* showed that the dilution factor for the untreated effluent was 256, which is still higher than the maximum value allowed for textile industry effluent, indicating that it is necessary to carry out treatment before the effluent can be discarded to water bodies in compliance with the legislation in force. The toxicity of the solution reduced considerably after pre-treatment with coagulation/flocculation, with a dilution factor of 16. It is evident that the dye under study (Reactive Black 5) has a toxic effect on the test organism. After the complete treatment process it was verified that the effluent was not toxic (dilution factor = 1), indicating that, in achieving the complete removal of color, the chemical products used during the pre-treatment stage do not increase the effluent toxicity at the end of the process.

5 Conclusions

The aluminum chloride coagulant demonstrated good results, and is suitable for the treatment of aqueous solutions containing reactive dyes. The best dosage found was 200 mg/L for Black 5 and 250 mg/L for Orange 16.

The pH had a strong influence on the medium under study; the color removal process was favored in the acid region, pH 6 and 3 showing high efficiency for coagulation and adsorption, respectively. The use of this adsorbent in final wastewater treatment processes is not recommended in cases where it is necessary to neutralize the effluent to comply with environmental legislation, considering that for the best adsorbent performance acid solutions are required.

The addition of sodium chloride to the synthetic wastewater favored the adsorption process, and the influence of increased temperature plus salt addition had an endothermic nature.

The reactivation experiments revealed that the adsorbent could be reused three times, consecutively, after the first adsorption with the virgin carbon.

In the evaluation of the acute toxicity with the bioindicator *Daphnia magna* as the test organism, the complete treatment process, besides having a good dye removal efficiency, reduces the toxicity of the final effluent.

Keywords: Urea thermal hydrolysis, Liquid non-ideality, Nakamura equation state, Modeling,
Topic: Industrial case studies & Environmental and food process and product modeling.

Abstract

In this work, the removal of urea from industrial wastewater by thermal hydrolysis is studied. The features of our model are (1) the use of Nakamura equation state and UNIQUAC equation for describing vapor and liquid equilibrium, (2) the use of multistage well-mixed for liquid and vapor flows with non-ideal rate-based, (3) the reaction assumed to take place in liquid phase. The model incorporates reaction rate of urea hydrolysis and takes into account the effects of solution non-ideality and back-mixing on the reactor performance. The rate of reaction is written in terms of activity of reactants which are determined using a thermodynamic framework for system of NH_3–CO_2–H_2O–urea mixture.

The model provides temperature and concentration distribution of different components in liquid and vapor phases along the height of reactor. Also the effects of key parameters on the performance of urea hydrolyser such as the steam flow rate and the temperature of wastewater has been examined. The result of this work shows that an increasing of inlet temperature of wastewater and steam flow rate improves the urea removal efficiency. The predicted data of the model are consistent with the plant data indicating the validity of the model.

Introduction & Process

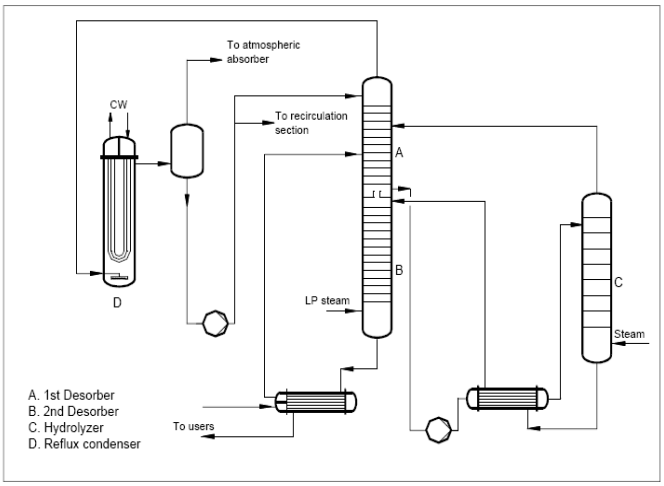
A urea plant produces water as well as urea. This water, which is contaminated, mainly by entrainment from the evaporation section, requires treatment if it is to be reused again. This process condensate generally contains about 2 to 9 percent by weight ammonia, 0.8 to 6 percent by weight carbon dioxide and 0.3 to 1.5 percent by weight urea.

It is now recognized by both the urea industry and the responsible governmental agencies that having urea-containing effluent streams may create possible environmental hazards. Therefore, several processes have been suggested for treating these urea-containing streams due to environmental restrictions. Which in the past decade, 100 ppm of urea was considered acceptable, but today's requirements mostly call for a maximum concentration of 10 ppm (Rahimpour, 2004).

A modern wastewater treatment consists mainly out of a first desorber column, which reduces the ammonia and carbon dioxide contents. For the next column, the hydrolyser, it is important that the ammonia and carbon dioxide concentrations at the inlet are sufficiently low, in order, not to reach the chemical equilibrium. Under these conditions the hydrolisation reaction proceeds towards the ammonia and carbon dioxide side, reducing the urea content to virtually zero.

* Corresponding author, Phone: +987112303071, Fax: +987116287294;
E-mail: rahimpor@shirazu.ac.ir (Prof. M. R. Rahimpour)

Contrary to other commercial hydrolysers, this hydrolyser is operated as a counter-current bubble column to improve the efficiency; water with urea meets continuously relatively clean vapours during its way through the column from the top to the bottom. The urea outlet of the hydrolyser is decreased to ppm level. In the second desorber column again operating at low pressure, the ammonia and carbon dioxide content are also decreased to ppm level.



There is no information available in the literature regarding the modeling and simulation of an industrial urea removal process by counter-current thermal hydrolysis method. Therefore, we decided to study more thoroughly the phenomenon of urea removal from industrial wastewater (Rahimpour and Azarpour, 2005).

Figure 3. Process Water Treatment System (khorasan petrochemical complex, 2008)

Reaction Scheme:

The urea first reacts with water to generate ammonium and carbamate ions, then ammonium and carbamate ions react to yield carbon dioxide and ammonia liquid:

$$NH_2CONH_2(l) + H_2O(l) \Leftrightarrow H_2NCOO^- + NH_4^+ \qquad \Delta H_{298} = -23 \ \frac{kJ}{mol} \qquad (1)$$

$$H_2NCOO^- + NH_4^+ \Leftrightarrow 2NH_3(l) + CO_2(l) \qquad \Delta H_{298} = 84 \ \frac{kJ}{mol} \qquad (2)$$

Reaction (1) is slow and exothermic, while reaction (2) is endothermic and fast in both directions, so that it could be considered at equilibrium under the conditions found in industrial thermal hydrolyser (Isla, Irazoqui, and Genoud, 1993). Therefore reaction (1) is the rate controlling step and its rate is considered as the overall rate of urea hydrolysis. For chemical reactions in thermodynamically non-ideal systems, as shown elsewhere (R.J. Madon and E. Iglesia, 2000), the rate becomes:

$$R = k_f\left(a_1a_2 - \frac{1}{K_{e,1}}a_3a_4\right) = k_f\left[(\gamma_1C_1)(\gamma_2C_2) - \frac{1}{K_{e,1}}(\gamma_3C_3)(\gamma_4C_4)\right] \qquad (3)$$

Where k_f is the forward reaction rate constant *($k_f=k_0\ exp(-E/RT)$)* and $K_{e,1}$ is the equilibrium constant of reaction (1). The experimental values of the preexponential factor and the activation energy in the Arrhenius expression of k_f are k_0 =3.75×10^7 *m^3/kmolh* and E =87780.3 *kJ/kmol* respectively (Aoki et al, 1999).The equilibrium constant for reactions (1) and (2) are defined as follows:

$$K_{e,j}(T) = K_{X,j}(X)K_{\gamma,j}(T,X); \quad j = 1,2 \qquad (4)$$

The following functional form:

$$\ln K_j(T) = \left(\frac{U_{1,j}}{T}\right) + U_{2,j}\ln T + U_{3,j}\,T + U_{4,j} \qquad (5)$$

was adopted to describe the temperature dependence of the *r* reaction equilibrium constant (Anderson et al, 1978). In the above equation, U_j is a constant related to reaction of number j where tabulated in Table 1.

Thermodynamic modeling

Table 1.	parameters			
function	U_1	U_2	U_3	U_4
$\ln K_{e,1}$	-31363	-64.26	-0.0595	482.11
$\ln K_{e,2}$	-11046	-5.19	0.01115	51.47

Urea processes are challenging to model from a thermodynamic point of view. In this study, the thermodynamic framework to describe liquid activity coefficients of molecular species in NH_3–CO_2–H_2O–urea system is based on the model developed by Isla et al. The liquid phase contains physically dissolved and chemically combined components that are mainly present as ions and molecules, namely H_2O(1), H_2NCONH_2(2), H_2NCOO^-(3), NH_4^+(4), CO_2(5), NH_3(6). The volatility of urea and ammonium carbamate are negligible and ions cannot leave from liquid phase to vapor phase, so there are only three molecular components including H_2O, NH_3, and CO_2 in the vapor phase.
In this work because of existence of gaseous mixture containing highly polar molecules (ammonia, water) and nonpolar molecule (carbon dioxide), a semiempirical equation of state (perturbed-hard-sphere (PHS) equation of state) is proposed which provides accurate estimates of thermodynamic properties for this gas mixture (Nakamura, Bread, and Prausnitz,1975).

Model development

The feed to the urea thermal hydrolysis reactor consists of liquid (water rich) stream entering from the top and pure high pressure steam stream entering from the bottom as the stripper. The movement of bubbles through the liquid phase causes mixing in the liquid phase. Moreover, there are several perforated plates at different levels inside the reactor in order to prevent back mixing and further mixing between the two phases. In this way a substantially zigzagging flow path of the liquid is created which crosses the substantially vertical flow path of the gaseous phase.
Therefore, for simulation purposes it will be approximated as a series of continuous multi-stage stirred tank reactors (CSTRs). Rahimpour et al. (2004) considered the whole co-current urea thermal hydrolysis reactor as a sequence of continuously stirred tank reactor (CSTRs). The same approach has been adopted in the present study for the hydrodynamic behavior of the counter-current urea hydrolysis reactor. The CSTRs in sequences will be referred to as stages, numbered from top to bottom. Stage 0 and 14 are index of specifications of liquid feed and steam streams respectively. The reaction kinetics is appropriately incorporated in the component balances. The enthalpy balances are expressed in terms of enthalpies of formation, which excludes the need for reaction enthalpies in these balances.

$$M_{i,j} \equiv V_{j+1}y_{i,j+1} + L_{j-1}x_{i,j-1} + \alpha_{i,1}H_j r_j + \alpha_{i,2}w - V_v y_j - L_j x_j = 0 \qquad \mathrm{i}=1,\ldots,\mathrm{M} \qquad \mathrm{j}=1,\ldots,\mathrm{N} \qquad (6)$$

$$H_j \equiv \sum_i^M V_{i,j+1}H_{i,j+1}^v + \sum_i^M L_{i,j-1}H_{i,j-1}^l - \sum_i^M V_{i,j+1}H_{i,j+1}^v - \sum_i^M L_{i,j}H_{i,j}^l = 0 \qquad \mathrm{j}=1,\ldots,\mathrm{N} \qquad (7)$$

$$E_{i,j} \equiv K_{i,j}x_{i,j} - y_{i,j} = 0 \qquad \mathrm{i}=1,\ldots,\mathrm{M} \qquad \mathrm{j}=1,\ldots,\mathrm{N} \qquad (8)$$

$$S_j^x \equiv \sum_i^M x_{i,j} - 1 = 0 \quad , \quad S_j^y \equiv \sum_i^M y_{i,j} - 1 = 0 \qquad \mathrm{j}=1,\ldots,\mathrm{N} \qquad (9)$$

$$P_j \equiv p_{j+1} - \Delta p_j - p_j = 0 \qquad \mathrm{j}=1,\ldots,\mathrm{N}\text{-}1 \qquad (10)$$

Model validation

The validation of steady state model was carried out by comparison of model results with the plant data under the design specifications and input data. The model results and the

corresponding observed data of the plant are presented in Table 2. It was observed that, the steady state model performed satisfactorily well under industrial conditions and a good agreement was obtain between plant data and simulation data which confirm that the proposed model can be considered suitable and reliable.

Comparison of calculated results with the observed plant data under the design specifications and input data (khorasan petrochemical complex, 2008)

Table 2.	Liquid phase output			Vapor phase output		
	observed	model	Error	observed	model	Error
Temperature (°C)	207	207.6	+0.3%	194.2	193.3	0.5%

Result & discussions

The simulation results were plotted as profiles of the dependent parameters versus independent variables. In addition, the effects of different parameters on the urea removal performance were investigated.

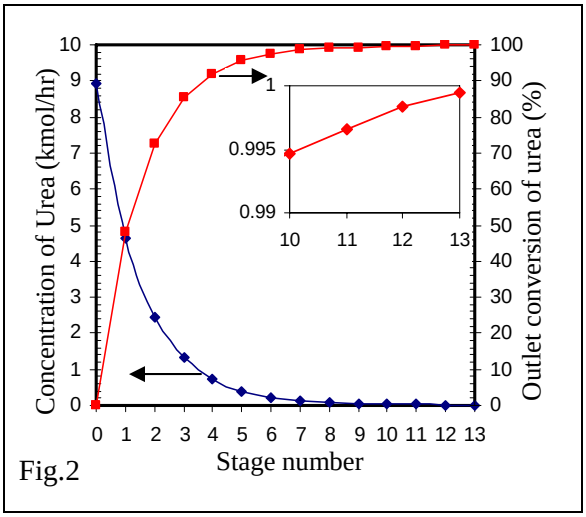

Fig.2

Figure 2 shows conversion and concentration of urea along the hydrolyser. It should be noted that the outlet urea content of the hydrolyser is virtual zero due to hydrolysis reaction and conversion is approximately complete. As liquid moves from top to bottom of the hydrolyser, it undergoes changes in temperature, which is shown in Fig. 3. It can be seen that there are two parts in this figure. At the first segments of hydrolyser, the temperature of reacting material decreases owing to the endothermic reaction, then increases by the injection of high pressure steam as demonstrated in. Figures 4-6 show the concentration profiles of ammonia, carbon dioxide and water along the reactor in the liquid and vapor phases. As can be seen in figure 4 and 5, concentrations of the ammonia and carbon dioxide increase in the liquid phase. These profiles clearly show the production of these components due to reaction as liquid moves down the hydrolyser. Inlet temperature of wastewater has an influence on the removal performance as demonstrated in figure 7. This figure indicates the increasing the inlet temperature of wastewater improves the removal performance due to endothermic reaction. The role of steam mass flow rate in urea removal for a specified inlet wastewater temperature is shown in Figure 8. As can be seen from this figure, higher steam mass flow rate maintains a higher temperature level in the reactor which would cause changes in liquid temperature profile and in extent of hydrolysis reactions. In addition, enhances the urea removal efficiency.

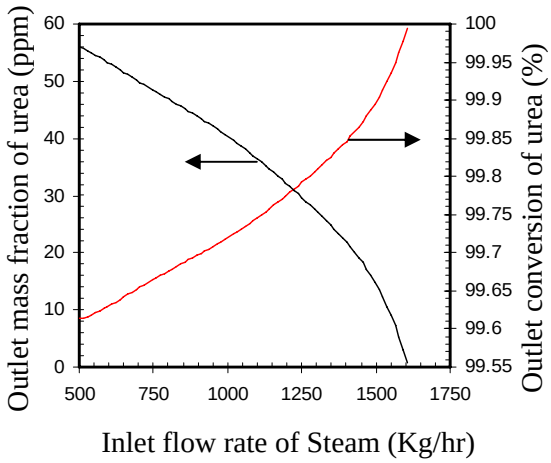

Figure 8

Conclusion

Urea thermal hydrolyser can remove urea from waste stream effectively, so that all components including the water can be recycled and reused in the plant. The model could be used to study the effects of process variables, such as temperature of wastewater and flow rate of steam on the reactor performance. It is also useful for a better control of the currently operating units and in the design of new hydrolysis plants.

Nomenclature

C_i	concentration of component i (kmolm^{-3})
E	activation energy (kJ kmol^{-1})
F_i	molar flow rate of component i (kmol h^{-1})
H_i	Liquid holdup in stage j (m^3)
$H_{i,j}^{v}$	Enthalpy of component i in vapor phase in stage j (kj/kmol)
$H_{i,j}^{l}$	Enthalpy of component i in liquid phase in stage j (kj/kmol)
ΔH	heat of reaction (kJ kmol^{-1})
i	component number
j	stage number
$K_{i,j}$	the equilibrium constant
K_0	pre-exponential factor of urea hydrolysis rate constant (m^3 kmol^{-1} h^{-1})
$K_{e,1}$	the equilibrium constant of reaction 1
K_f	the forward reaction rate constant (m^3 kmol^{-1} h^{-1})
$K_{x,j}$	equilibrium constant of reaction j dependent on temperature and mole fraction
$K_{\gamma,j}$	equilibrium constant of reaction j dependent on mole fraction
L_j	mole flow rate of liquid in stage j (kmol h^{-1})
M	Number of components
N	Number of stages
$L_{i,j}$	liquid mole flow rate of component i in stage j (kmol h^{-1})
P_j	Peressure of stage j (bar)
ΔP_j	pressure drop (bar)
r	overall rate of reaction (kmolm^{-3} h^{-1})
T	temperature (K)
U	constant Eq.5
V_j	mole flow rate of vapor in stage j (kmol h^{-1})
$V_{i,j}$	vapor mole flow rate of component i in stage j (kmol h^{-1})
w	consumption molar flow rate of carbamate in reaction (2) (kmol h^{-1})
x_i	mole fraction of component i in liquid phase
y_i	mole fraction of component i in vapor phase

Greek letters

$\alpha_{l,1}$	stoichiometric coefficient of species i in reaction 1
$\alpha_{l,2}$	stoichiometric coefficient of species i in reaction 2
γ_i	activity coefficient of component i

Keywords: Hydrogen peroxide (H_2O_2), Kinetics, UV radiation, Slaughterhouse, Water reuse.
Topic: Sustainable process-product development through green chemistry.

Abstract

Guidelines and regulations, with respect to the use and reuse of water or wastewater in the food industry, have been created which accepted or do not restrict the use of non-potable water as process water or water treated for direct reuse as drinking water. However, careful analysis is needed in each case based on a complete knowledge of the risk involved for the safety of the food production and the health of the consumers. Advanced oxidative processes (AOP) increasingly are studied to provide treated water as a source of indirect reuse with or without characteristics of drinking water, however, excluding any risk to product integrity, environment and health of distributers and consumers in household and industry. To ensure that these topic will be reached our objectives in this study were to evaluate the kinetics of the degradation of wastewater constituents, e.g., especially compounds with aromatic structures using UV or UV/H_2O_2, in order to achieve the characteristics for a subsequent water reuse.

1 Introduction

The necessity to save water as the most important food stuff of man is crucial because of the finite nature of this resource. Therefore, the sustainable use of water demands the direct reuse of water. The consumption of water in many parts of the world is increasing in household, agrarian and industrial activities. Confronted with these issues, agencies world-wide have recognized and stimulated the implementation of techniques to treat wastewater to such an extent that characteristics of drinking water quality will be reached to make a direct or indirect wastewater reuse possible according to the Codex Alimentarius (2001). Advanced biological treatment techniques in combination with physicochemical and/or chemical treatment steps were performed. Thus advanced oxidation processes (AOP) have developed as a powerful tool to degrade organic pollutants via oxidation transforming the vast majority of organic contaminants in carbon dioxide, water and inorganic ions when applied after an effective biological treatment. The degradation reactions involve transitional oxidants such as hydroxyl radicals (●OH). These radicals can be generated by reactions involving strong oxidants such as ozone (O_3) and hydrogen peroxide (H_2O_2), ultraviolet radiation (UV), and semiconductors such as titanium dioxide and zinc oxide.

The reaction mechanism of hydrogen peroxide photolysis by UV radiation and degradation of organic compounds (RH) by the action of hydroxyl radicals are divided into four stages of reactions (eq. 1-8): Initiation, propagation, termination and decomposition (Alfano et al., 2001):

* Corresponding author. Tel + 55 48 37219448, r. 240. E-mail: danielledebem@yahoo.com.br

Initiation: (1) $H_2O_2 \xrightarrow{h\nu} 2 \bullet OH$

Propagation: (2) $H_2O_2 + \bullet OH \xrightarrow{k_2} HO_2 \bullet + H_2O$

(3) $H_2O_2 + HO_2 \bullet \xrightarrow{k_3} \bullet OH + H_2O + O_2$

Termination: (4) $2 \bullet OH \xrightarrow{k_4} H_2O_2$

(5) $2HO_2 \bullet \xrightarrow{k_5} H_2O_2 + O_2$

(6) $\bullet OH + HO_2 \bullet \xrightarrow{k_6} H_2O + O_2$

Decomposition: (7) $RH + \bullet OH \xrightarrow{k_7} \text{products}$

(8) $RH + HO_2 \bullet \xrightarrow{k_8} \text{products}$

However, when natural water matrices (e.g., superficial, ground water or wastewater) are used, natural organic matter and alkalinity are the main ●OH scavengers and in addition amplify light scattering. These effects influence the degradation effectiveness for organic compound (Chen et al. 2007). However, the presence of nitrate, iron (III) and organic matter in low concentration can increase the degradation rate due to photo-oxidation of these compounds using UV or other AOP steps in combination with UV, e.g., UV/H_2O_2. Nitrate ions absorb UV light, acting as an internal filter to UV light and in parallel can form hydroxyl radicals (●OH) by the mechanism presented below (eq. 9-13) (Neamtu and Frimmel, 2006).

(9) $NO_3^- \xrightarrow{h\nu} NO_2^- + O$

(10) $NO_3^- \xrightarrow{h\nu} NO_2 \bullet + O \bullet^-$

(11) $NO \bullet + H_2O \longrightarrow NO_2^- + NO_3^- + 2H^+$

(12) $O + H_2O \longrightarrow 2HO \bullet$

(13) $O \bullet^- + H_2O \longrightarrow HO \bullet + HO^-$

At wavelengths larger than 300 nm, aqueous ferric ion complexes can provide ferrous ions and hydroxyl radical undergo photolysis by an internal transfer of electrons (eq. 14) (Espinoza et al., 2007).

(14) $Fe(OH)^{2+} \xrightarrow{h\nu} Fe^{2+} + \bullet OH$

Dissolved organic matter absorbs UV light and can generate reactive radicals such as singlet oxygen, superoxide anions (●O^{2-}), hydroxyl radicals (●OH) and peroxyl radicals (ROO●). These reactive transients can degrade the organic pollutants following different pathways; consequently, they would not be degraded only by direct photolysis (Chin et al., 2004, Neamtu and Frimmel, 2006).

The main objective of this study was to evaluate the degradation kinetics of aromatic compounds applying UV or UV/H_2O_2 in order to achieve the characteristics for water reuse considering the restrictions imposed by Brazilian legislation and hygiene concerns in particular to food industry. Therefore, following those regulations, water reuse must be applied in processes without contacting food product.

2 Materials and methods

2.1 Sample collection and their analysis

Four treated wastewater samples representative of the effluents of the wastewater treatment plant (WWTP) of a Brazilian poultry and swine slaughterhouse were sampled in 2007. The samples were kept in darkness at 4°C to preserve their physicochemical characteristics. The samples differed in their characteristics, as shown in Table 1. The compounds resistant to biological treatment processes were detected and identified by LTQ orbitrap mass spectrometer (Thermo Electron, Germany) applying electrospray ionization (ESI) after liquid chromatography (LC) applying high-resolution mass and tandem mass spectrometry (LC-(HR)MS and -MS^n). Nonylphenols (NP), octylphenols (OP), linear alkylbenzene sulfonates (LAS) and ibuprofen were detected in negative ion mode. In the positive ion mode the precursor compounds of NP and OP, nonylphenol ethoxylates (NPEO), octylphenol ethoxylates (OPEO) and polyethylene glycols (PEG) besides erythromycin, sulfamethoxazole and sulfadimidine were detected and identified.

Table 1 Concentration ranges of the treated wastewater from slaughterhouse

	Range	***DW[a]***
Apparent Color, Pt/Co units	-	15.0
Chemical Oxygen Demand, mg L^{-1}	18.9-95.0	-
Chloride, mg L^{-1}	120.0-150.0	250.0
Nitrate, mg L^{-1}	10.2-17.4	-
pH, at 25°C	7.3-7.6	6.0– 9.5
Real color, mg L^{-1} Pt-Co	33.5-62.2	-
Total coliforms, CFU/100 mL	1000-58000	none
Total iron, mg L^{-1}	3.5-7.0	0.3
Turbidity, FTU	3.8-30.0	5.0
UV_{254} absorbance, m^{-1}	15.2-18.4	-

[a] Limitations for water to be used as drinking water in Brazil.

2.2 Treatments and kinetics

Two different treatment methods were evaluated in order to achieve the drinking water parameters that are required to water reuse in food industry: (A) ferric coagulation followed by UV radiation; and (B) ferric coagulation followed by UV/H_2O_2 treatment. Color, turbidity, total organic carbon (TOC), chemical oxygen demand (COD), total coliforms and aromatic compound content (UV_{254}) were the parameters followed to evaluate the performance of UV and UV/H_2O_2 processes they were measured before and after each treatment step. The combined treatment of coagulation followed by UV aimed to remove turbidity to facilitate UV efficiency in mineralization of pollutants and disinfection.

The optimization of the ferric coagulation process (FC) was performed in jar tests. The stock solution of ferric sulphate was 5 g Fe^{3+} L^{-1}. The volume of wastewater samples used for each beaker in jar test was 300 mL applying an iron concentration in the range of 5 – 25 mg L^{-1} in combination with a pH in the range of 4.5 – 7.0, adjusted by NaOH or H_2SO_4 addition. The experiment using a Fe(III) concentration of 16 mg L^{-1} and a neutral pH resulted in a maximum turbidity removal and therefore, was chosen as optimized condition.

The wastewater in the UV batch reactor (Trojan UV MaxTM, Model E) was radiated by a UV-lamp (15W) with a light intensity of 2.64 $x10^{-3}$ einstein min^{-1}. For radiation UV light with wavelengths between 300 and 410 nm and a maximum in radiation at 355 nm. The UV photolytic treatment was carried out in triplicate at pH 7.0 and ambient temperature. For UV/H_2O_2 treatment a pH of 4.0 and an ambient temperature was chosen. The initial concentration of hydrogen peroxide was given by the Cruncher number ([H_2O_2]/COD = 2).

The sampling for determination of degradation kinetics under UV_{254} was performed till absorbance reached 1.0 m^{-1}. The time necessary to reach that concentration is the reaction time (t_r).

2.3 Analytical methods

Apparent and real color, COD and $COD_{dissolved}$, suspended solids, UV_{254} absorbance were analyzed according the Standard Methods (1998). Apparent and real colors were determined by spectrophotometric detection at wavelength 455 nm. These two types of color were determined by the presence of turbidity in the sample: with "apparent color" colloidal and dissolved compounds that cause color and larger particles that cause turbidity were recorded, while the real color determination recorded dissolved compounds responsible for color after a removal of turbidity. COD and $COD_{dissolved}$ were determined by "Closed Reflux, Colorimetric Method" while UV_{254} absorbance was determined using an UV spectro-photometer at wavelength 254 nm (Shimadzu 1650C UV).

Nitrate, total coliforms and total iron were measured using reagents and instructions of HACH and the measurements were made by HACH spectrophotometer DR/2000. Turbidity and pH were measured by a turbidimeter (Instrutherm TD-200) and pH-meter (Micronal B474 and Lutron PH-206). Total coliforms were determined using ColiGel™ Test. Each ColiGel™ bag can detect a single microorganism in 100 mL water sample and uses X-gal indicator to produce an indigo blue positive reaction.

3 Results and Discussion

The efficiency of each treatment is presented in Table 2. Ferric coagulation showed high removal of COD and TOC, but low efficiency to remove turbidity and aromatic compounds. The irradiation with UV light diminished the aromatic compound content and turbidity, because UV decomposes organic matter by double bonds cleavage (Benitez et al., 2003). This removal can also be due to the formation of ●OH radicals by UV photolysis of natural compounds found in water and also present in treated effluents: nitrate, iron (III) and dissolved organic matter such as fulvic and humic acids as mentioned above. The addition of H_2O_2 was also efficient to remove aromatic compounds. The reaction time (t_r) to reach UV_{254} = 1.0 m^{-1} decreased from 600 or 840 min to 265 min by UV treatment or UV/H_2O_2 treatment, respectively.

Table 2 Removals rates under different treatment methods

	A*	***B****	***C****		***A****	***B****	***C****

*) **A** (FC): Wastewater after ferric coagulation, pH_{final} = 7.1. **B** (FC+UV): Wastewater treated by ferric coagulation followed by UV treatment (t_r = 600-840 min UV exposure), pH_{final} = 7.3. **C** (FC+UV/H_2O_2): Wastewater treated by ferric coagulation followed by UV/H_2O_2 treatment (t_r = 100 min UV exposure), pH_{final} = 7.4.

The microbiological parameter "total coliforms" was diminished by coagulation treatment and AOP treatment. FC treatment yielded an efficient removal of 99.4% by direct sedimentation of microorganisms as by adsorption onto flakes. The removal efficiency was better than the limit of removal disclosed by Achilleos et al. (2005) which varied between 40 and 80% of removal of bacteria during coagulation. During the application of AOP treatment steps UV

and UV/H_2O_2 the removal of 100% of total coliforms may not be due only to the bactericidal action of UV light, but also by the presence of ferric ions added in coagulation treatment. If Fe(III) was added, there might be two more ways for disinfection. The first way is the formation of ●OH radicals by photolysis of complex ferrous dissolved in water (eq. 14). The second possibility is due to the formation of intracellular processes induced by Fenton and Photo-Fenton. Hydroxyl radicals (●OH), superoxide anions and hydrogen peroxide cause oxidative stress resulting in the damage to proteins, nucleic acids and cell membranes (Rincón and Pulgarin, 2006).

The kinetics of aromatic content removal showed that the addition of hydrogen peroxide increased the rate of aromatic compounds decomposition and both processes following a pseudo-first order kinetic model (Figure 1). The pseudo-first order constants and the time required to reduce half of the initial concentration of aromatic pollutants (half-life time) by UV were: $k_{UV_{254}}$ = 0.0056 min^{-1} and $t_{½,UV_{254}}$ = 123.8 min while for the treatment UV/H_2O_2: $k_{UV_{254}}$ = 0.0306 min^{-1} and $t_{½,UV_{254}}$ = 22,6 min.

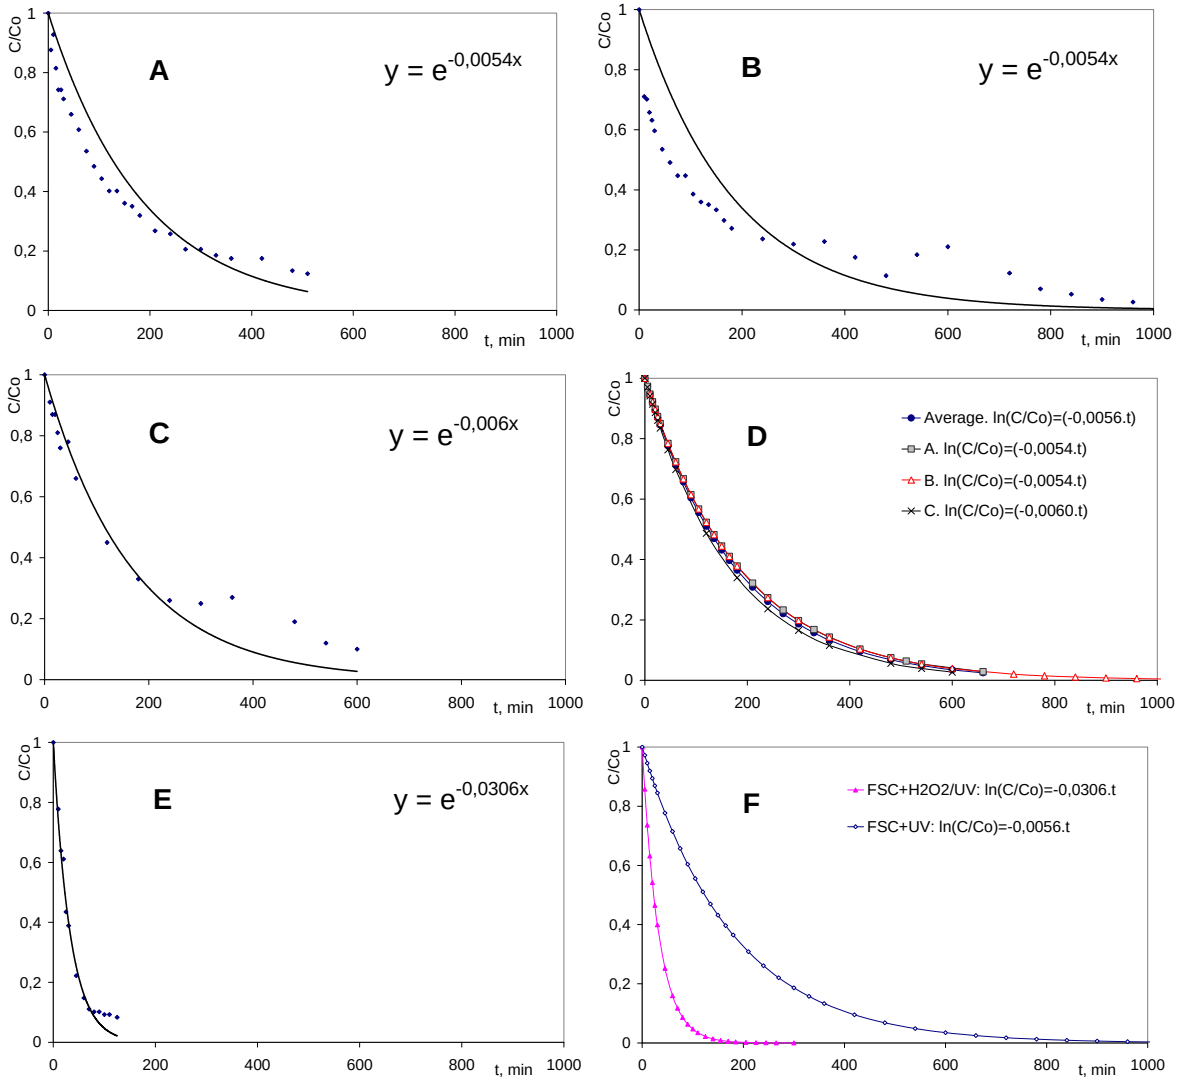

Figure 1 (A, B, C) Pseudo-first order degradation kinetics of UV_{254} absorbance: FC + UV: experiments; (D) Optimized and averaged curves of (A, B, C); (E) FC + UV/H_2O_2; (F) Combined and optimized curves of (E) and (D).

The expected raise of the UV_{254} degradation rate by adding H_2O_2 could not be observed. One explanation may be due to the reduction of ●OH radicals in the steady-state due to the

scavenger effect of natural compounds found in wastewater and also present in sewage treatment plant effluents. Chen et al. (2007) indicated that total organic carbon present in the wastewater effluents consumed ≥ 70% of ●OH radicals generated in natural water.

3 Conclusions

In conclusion, both AOP methods tested were able to degrade organic compounds contained in slaughterhouse wastewater after biological treatment. The combined treatment using ferric coagulation followed by UV/H_2O_2 in the degradation of aromatic compounds, however, was 5.2 times faster than ferric coagulation in combination with UV treatment. Therefore this method can be assumed to be an efficient and economical alternative in the treatment of biologically treated slaughterhouse wastewater to reach drinking water parameter quality enabling indirect and direct water reuse in slaughterhouse industry.

Topic: Sustainable process-product development through green chemistry.

Abstract

Pharmaceutical compounds such as non-steroidal anti-inflammatory drugs (NSAIDs) have been detected in treated wastewater, aquatic environment and even in drinking water in many parts of the world. Although health effects of the consumption of pharmaceuticals at low concentration levels are not yet completely elucidated, drinking water should not contain such compounds. Membrane bioreactors (MBRs) in combination with different physicochemical and advanced oxidation processes (AOPs) have been developed as promising technologies for the complete elimination of polar and persistent pollutants of high concern, especially pharmaceutical compounds. However, available information on the performance of MBRs regarding removal of pharmaceuticals is currently limited. This paper evaluates the treatment of three NSAIDs of large consumption worldwide (acetaminophen, ketoprofen and naproxen) by MBR combined with AOP. The identification and quantification of the compounds along the different treatment steps applied during the study was performed with liquid chromatography coupled with high resolution mass spectrometry (LC-MS).

1 Introduction

The occurrence of pharmaceutically active substances in the environment has become an important issue in the last few years. These drugs, their metabolites and bacterial transformation products, which can be even more harmful than the parent compound, are continuously released into the environment. Recent improvements in substance specific analytical techniques today allow the detection of trace levels of pharmaceuticals in wastewater effluents, surface and ground waters as well as drinking waters (Gebhardt and Schröder, 2007).

Non-steroidal anti-inflammatory drugs (NSAIDs) belong to a class of pharmaceuticals that are extensively used worldwide and their consumption only in developed countries is estimated to be higher than several hundred of tons per year (Daughton and Ternes, 1999). To obtain the desired therapeutic results the drugs are designed to resist degradation while in parallel for renal excretion after use they are equipped with polar structures, which may be responsible for their incomplete elimination during conventional biological wastewater treatment thus reaching the environment via wastewater discharges.

These compounds of concern may induce toxic effects to aquatic organisms disturbing the ecological balances, e.g., leading to the development of multi-resistant strains of bacteria. To eliminate these compounds of concern it is necessary to improve wastewater treatment because sewage treatment plant (STP) discharges are well known as predominant point sources for these drugs (Andreozzi et al., 2003). For this purpose, membrane bioreactor (MBR) and advanced oxidation processes (AOPs) have been presented as promising technologies towards the degradation of polar persistent compounds, especially pharmaceuticals.

In this study, three NSAIDs with worldwide large consumption rates (acetaminophen, ketoprofen and naproxen) were selected to monitor their fate and their removal efficiency during MBR and AOP treatment. The detection, identification and quantification of the drugs along the different treatment techniques applied during this study were performed using liquid chromatography coupled with high resolution mass and tandem mass spectrometry (LC-(HR)MS and -MS^n).

2 Material and methods

2.1 Chemicals

Ultra-pure water used in all treatments or as LC eluent component was prepared using a Milli-Q system (Millipore, Milford, MA, USA). All solvents used as mobile phases, for desorption of the pharmaceuticals and their potential degradation products extracted by solid phase extraction (SPE) were Nanograde solvents purchased from LGC Promochem (Wesel, Germany). All other chemicals used were of “Analytical Reagent” or of “Residue Analysis” purity grade with the exception of hydrogen peroxide solution 30% (H_2O_2) applied in AOP examinations was of "medical extra pure" grade (Merck, Darmstadt, Germany). All gases applied were products of Linde, Germany, and were of 99.99% purity with the exception of oxygen with the purity “medical grade” which was used for the O_3 generation applying an ozone generator from Sander (Uetze-Eltze, Germany).

2.2 Pharmaceuticals

The three NSAIDs acetaminophen, ketoprofen and naproxen were purchased from Sigma-Aldrich. Relevant information about these pharmaceuticals is given in Table 1. Concentrated stock solutions were prepared in methanol for analytical determination and for spiking purposes. To avoid degradation during the test period solutions were kept at -18°C.

Table 1. Name, CAS N°, sum and structural formula, pK_a and log K_{OW} of NSAIDs under research (Jones et al., 2002; Khan and Ongerth, 2004; Urase and Kikuta, 2005; Ternes et al., 2007).

Name	CAS N°	Formula	Chemical structure	Acid, base or neutral	pK_a	Log K_{ow}
Acetaminophen	103-90-2	$C_8H_9O_2N$		N	9.39	0.46
Ketoprofen	22071-15-4	$C_{16}H_{14}O_3$		A	4.45	3.12
Naproxen	22204-53-1	$C_{14}H_{14}O_3$		A	4.15	3.18

2.3 Membrane bioreactor (MBR) pilot plants

Wastewater used as feed for the MBR pilot treatment plants was taken continuously from the effluent of the pre-settling tank of the municipal STP of Aachen, Germany. MBR treatment was performed over a period of 4 weeks. The sludge retention time (SRT), sludge concentration (SC) and the hydraulic retention time (HRT) of the pilot-plants were 15d, 12 g/L and 9h for MBR-15, and 30d, 12 g/L and 13h for MBR-30, respectively. Both MBRs used in this study were equipped with 1.43 m^2 of hollow-fiber ultrafiltration (UF) membranes (PURON, KMS Germany). The nominal pore size and material of the membranes were 0.04 µm and polyethersulfone (PES), respectively. A steady-state was reached over 6 months before the tests started. The pharmaceutical compounds were spiked into the feed of each MBR to reach a steady-state concentration of 50 µg/L. During the week spiking was performed by the addition of 2/3 (33.33 µg/L) of the total daily spiking quantity in the morning (10:00 a.m.) and 1/3 (16.67 µg/L) in the afternoon (04:00 p.m.). Spiking during the weekend was performed by the addition of the total amount of 50 µg/L at 04:00 p.m. in the afternoon. Every day at 03:00 p.m. in the afternoon samples of 500 mL of each MBR and of permeates were taken. In parallel, 16L (MBR-15) or 8L (MBR-30) of excess MBR sludge were discharged in order to keep the sludge concentration (SC) in both MBRs constant.

2.4 UV radiation, O_3 and AOP experiment

The advanced treatment techniques applied in this study were H_2O_2/UV, H_2O_2/Fe^{2+} (Fenton), H_2O_2/Fe^{2+}/UV (photo-Fenton), UV radiation and ozone. Solutions of NSAIDs (100µg/l of each one in Milli-Q water or in MBR permeate), isolated or as a mixture, were prepared prior the AOP treatments from the standard solutions. All treatments were performed at room temperature and the pH was adjusted to 3.0 for a better comparison of the results. The experiments applying H_2O_2/UV, Fenton, photo-Fenton and UV radiation were performed in a glass cylindrical reactor system (500 mL) along 30 min. A 15 W medium pressure mercury lamp (Heraeus, Hanau, Germany), surrounded by a quartz thimble, was used when necessary as UV source. The quartz thimble was double-walled and water was used in a cooling circuit to maintain a constant temperature. The agitation of the system was realized by a magnetic bar. Ferrous sulfate heptahydrate was used as font of iron for the Fenton and photo-Fenton process. Iron concentration of 3.4 mg/L and hydrogen peroxide concentration (30%) of 17 mg/L were used in the experiments. For ozonation experiments Milli-Q water contained in a glass reactor was brought to ice bath temperature prior to saturation with ozone. For this purpose ozone generated from oxygen was fed into the reactor using a sintered glass plug located at the botton of the reactor. After time intervals of 1,2,5,10,20 and 30 min, a 1 mL of aliquot of O_3–saturated water was taken and added to flasks containing 1 mL of a solution of 100 µg/L of selected drugs, dissolved in Milli-Q water or in MBR permeates. After a reaction time of 30 min the samples then were analyzed without further sample preparation by LC/MS and MS^n in order to get qualitative, quantitative and structural information about ozone degradation products.

2.5 Sampling preparation

The pharmaceuticals and their metabolites present in the MBR permeates were concentrated using commercially available solid phase extraction (SPE) cartridges (1 ml) filled with 100 mg of Isolute ENV+ material from IST (Mid Glamorgan, UK). Prior to use they were handled as prescribed by the manufacturer. After the SPE procedure, the cartridges were rinsed with ultra-pure water to remove salts before they were dried in a gentle stream of nitrogen at 30°C. The pharmaceuticals adsorbed were desorbed by the addition of 6 x 1 mL of methanol. STP eluates were brought to dryness in a gentle stream of nitrogen at 60°C. The dry residues containing the pharmaceuticals were reconstituted in 1 mL of methanol/water (1:1) and were used for injection during LC-MS and -MS^n analyses.

2.6 Analytical procedures

Sodium chloride (NaCl) was applied as a tracer compound to ensure an ideal mixing in the MBRs. Its monitoring was performed using a conductivity probe. Identification and quantification of spiked pharmaceuticals in MBR permeates were performed by means of a LTQ Orbitrap mass spectrometer (Thermo Electron, Bremen, Germany) applying electrospray ionization (ESI), both in the positive (for acetaminophen) and in negative (for ketoprofen and naproxen) mode as described by Gerhardt and Schröder (2007). To calculate the efficiency of the pharmaceutical removal from the spiked wastewater, the concentrations in the MBR permeates were determined quantitatively using LC-MS after SPE. Metabolites present in permeates after MBR treatment and degradation products after AOP treatment were determined by extraction of selected mass traces from TICs recorded under high resolution MS (HRMS) and identified by LC-MS^n.

2.7 Liquid chromatographic and MS data

LC-separations were carried out with a Hypersil GOLD aQ column (RP5, 5 µm, spherical; 150 x 2.1 mm I.D.) equipped with a Hypersil GOLD aQ pre-column (10 x 2.1 mm I.D.), also filled with 5 µm, spherical material (Thermo Electron). Gradient elution by means of (A) methanol/water 90:10 (v:v) in combination with (B) Milli-Q-purified water/methanol 90:10 (v:v) was applied both containing 2 mM of ammonium acetate. The gradient was programmed as follows: Starting with 20% A/80% B the concentration was increased linearly to 90% A/10 % B within 12 min. Up to 20 min the composition was kept constant. The overall flow rate was 0.2 ml/min. Instrument control, data acquisition and data processing were performed using Xcalibur 2.0 software (Thermo Electron, USA).

3 Results and discussion

3.1 Removal of pharmaceutical compounds applying MBR-treatment

Figure 1 shows the mean removal rates for pharmaceutical compounds applying MBR treatment during 4 weeks. The compound acetaminophen showed the highest removal efficiency (about 100 %), due to its hydrophilic nature (log K_{ow} < 1) and also due to its less complex chemical structure, however, elimination could be cleared up as a biodegradation. Nevertheless these results are in agreement with the results reported by Kim et al. (2007) who obtained a 99% acetaminophen removal during the treatment of municipal sewage in a MBR pilot plant. Concerning the ketoprofen behaviour, an almost complete removal of the precursor drug can be observed for this compound in both MBRs (cf. Fig. 1). The compound ketoprofen has a hydrophobic nature (log K_{ow} > 3) and acidic character. According to Quintana et al. (2005), for polar compounds like acidic pharmaceuticals, microbial degradation is the most important removal process in activated sludge wastewater treatment while the retention by hydrophobic adsorption onto the membrane will not reduce concentration. Kimura et al. (2005) compared ketoprofen removal through MBR pilot plant and conventional activated sludge treatment (CAST) in municipal sewage effluent and reported a concentration of 300 ng/L of ketoprofen after CAST, while the concentration after MBR treatment was approx. 10 ng/L. The compound naproxen has similar physicochemical properties as ketoprofen, however, naproxen removal in both MBRs was lower than ketoprofen removal, and this partially can be explained by its more stable chemical structure (naphthalene ring system). According to the study by Quintana et al. (2005) on microbial degradation of pharmaceuticals, the degradation of naproxen was low with approximately 60% of transformation in 28 days and only one metabolite could be detected. Kimura et al. (2005) compare the removal of naproxen in municipal sewage effluents using either MBR pilot plant or CAST with the result that CAST led to a concentration of 50 ng/L of ketoprofen, while a concentration of approximately 20 ng/L after MBR was reached. Kim et al. (2007) reported a 41% removal of naproxen from domestic sewage after treatment in a pilot scale MBR.

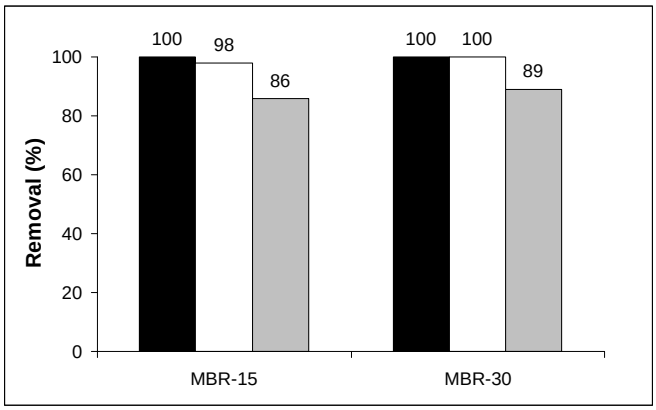

Figure 1 - Elimination rates of NSAIDs during 4 weeks applying MBR treatment with SRT of 15 (MBR-15) or 30 (MBR-30) days (acetaminophen ■ , ketoprofen ❑ , naproxen ▩).

3.2 Removal of NSAIDs by UV radiation, O_3 and different AOP treatment steps

Figure 2 shows the elimination of the pharmaceutical compounds after 30 minutes applying UV radiation, O_3 and AOP treatments. With regard to acetaminophen, Andreozzi et al. (2003) reported that at pH 2.0 and 7.0, 800 mg/L of acetaminophen could be completely degraded within 20 min using an large excess of O_3 (72 g/h) while slightly lower oxidation rates were observed with 170 mg/L of H_2O_2/UV at pH 5.5 applied to 1.51 mg/L acetaminophen resulting in an elimination rate of > 90% combined with a TOC removal of 40%. Comparing these results with the data reported here, we recognized that the efficiency of H_2O_2/UV for the reachable oxidation of acetaminophen was lower. Only 66.3% were degraded within 30 min. Concerning ketoprofen removal, it can be observed in Fig. 2 that ketoprofen is a compound that has a high sensitivity to UV light, although the mechanisms and the possible pathways are still under investigation. Nakajima et al. (2005) studied the photodynamic action of ketoprofen, determining the generation of free radicals and active oxygen species by photo-irradiation, as well as the identification of 3 different degradation products. In our results, UV radiation induced a high destruction rate of ketoprofen already within the first minute, which led to the complete elimination of the parent compound during this short reaction period. Few data were available about the degradation of naproxen, the third NSAID compound, as well as the formation of degradation products. According to Isidori et al. (2005), phototrans-formation appears to be its main elimination process in the environment, where naproxen in water can be partly transformed by irradiation into different photoproducts. From our results it was recognizable that O_3 besides photo-Fenton seemed to be the most efficient oxidation treatment step for naproxen, reaching elimination of 100 or > 90 %.

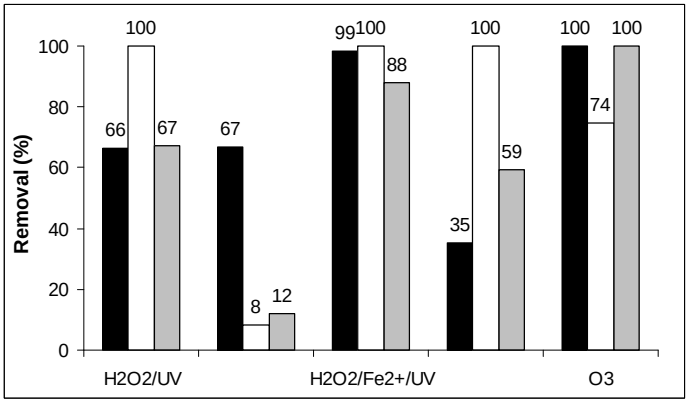

Figure 2 – Mean elimination rates of NSAIDs by UV radiation, O_3 and AOPs over a period of 30 min to MBR permeates (acetaminophen ■ , ketoprofen ❑ , naproxen ▩).

4. Conclusions

The performance of two MBR pilot plants with submerged membranes, operated with different SRTs, for the removal of selected drugs, could be examined in this study. The effect of sludge retention time (SRT) on the removal efficiency of the compounds was slightly higher in MBR with SRT of 30 days (MBR-30) compared to SRT of 15 days (MBR-15). The compounds acetaminophen and ketoprofen exhibited highest removal efficiencies, while naproxen resisted microbial attack with lower removal rates in both MBRs. Concerning the potential mechanisms responsible for the removal of the target pharmaceuticals in MBRs (sludge sorption + biodegradation + membrane retention), it was not possible to determine exactly to what extent each mechanism contributed to the removal efficiency. Membrane retention using ultrafiltration membranes can be neglected, biodegradation, however, played an important role, since higher removal efficiencies were obtained for higher SRTs. Nevertheless, elimination by MBR treatment using ultrafiltration was only partially successful and therefore, persistent pharmaceuticals in small concentrations and their metabolites were discharged with the wastewater into the environment. Concerning those results obtained with an advanced treatment, it can be concluded that oxidation method using O_3 would be a powerful tool for a complete elimination of the target compounds. In conclusion, results indicated the importance to investigate the environmental fate of NSAIDs and their mainly unknown polar metabolites. Therefore additional research is overdue first to recognize the parent drugs and their metabolites and then to assess the effect of these pollutants to the environment.

Keywords: Adsorption, Equilibrium, Dyestuffs, Kinetics, Textile wastewater
Topic: Sustainable process-product development through green chemistry

Abstract

In this work a natural waste from almond production was used. Its culture is widespread in Mediterranean climate areas, namely in some regions of Portugal, so these wastes are easily available. This waste was tested for removal of basic dyestuffs from textile wastewaters.

The basic dyestuff Red Astrazon FBL 200% (CI basic red 46), from Dystar is an azo dye and was selected for this study based on preliminary tests. Batch equilibrium and kinetic studies were performed for the selected system.

Langmuir or Freundlich models can fit equilibrium batch studies. It is observed an increase of adsorption capacity with temperature, from 15±3 to 30±11 mg/g, indicating that adsorption is rather favoured at 41 than at 20ºC. The pH influence was tested in t he range 4.5 to 9 and was not considered significant, under testing conditions. The presence of auxiliary dyeing agents, as occurs in a real effluent, gave rise to the development of microrganisms along the 13 days of contact time.

The kinetic experiments were well described by the pseudo-second order model, using a experimental equilibrium concentration of 2.44 mg/g and a 80 ±14 g/(g min) kinetic constant.

1 Introduction

It is nowadays well known that there is a need of treating textile wastewaters, not only concerning primary and secondary treatments for organic matter and suspended solids removal, but also a tertiary treatment, mostly for residual colour removal.

Textile dyestuffs should be removed from wastewaters because they can cause reduction in the primary production that will affect the aquatic ecosystem, and also for aesthetical reasons. Besides, some of them may also be toxic.

Activated carbon is one of the most widely used adsorbents for colour removal in wastewater treatment. However, this treatment needs a high investment and leads to high operation costs, due to the high price of the activated carbon and to the high wastewater flow rate always involved, which can be greatly increased when there are no regeneration units nearby, as in the case of Portugal.

Research has recently been directed towards alternative adsorbents, namely low cost adsorbents, including natural and waste materials. Many research works studying valuable alternatives to activated carbon for dyestuffs removal appeared, using: inorganic adsorbents such as, sepiolite (Santos and Boaventura, 2008) and natural zeolites (Meshko et al., 2001); natural adsorbents from vegetal source, like hardwood (Asfour et al., 1985), and from animal source, like Anodonta shell, Squid and Sepia pen (Figueiredo et al., 2005).

In this work a natural waste from almond production was used. Its culture is widespread in Mediterranean climate areas, namely in some regions of Portugal, so these wastes are easily available. This waste was tested for removal of basic dyestuffs from textile wastewaters.

Basic dyestuffs are water-soluble cationic dyes that can be applied to acrylic fibres, wool, silk, leather and modified cotton (Venkataraman, 1972). Their use has been increasing due the increment of acrylic fibres production especially in Asia, where most of the textile industries are located (Dobson, 2001).

According to Anliker et al. (1988), basic dyes have been classified as toxic colorants; they are considered as one of the more problematic classes of dyes by some authors (El Quada et al., 2008). Moreover, the basic dyestuff selected for this study is an azo compound; their metabolites (such as aromatic amines) might be either carcinogenic or cancer suspect agents (Reife and Freeman, 1996).

2 Methods

2.1 Dyestuff preparation

The basic dyestuff Red Astrazon FBL 200% (C.I. basic red 46), kindly supplied by Dystar, was selected for this study; it is an azo dye and its structural formula is presented in figure 1. Dyestuff solutions were prepared with distilled water, with a 25 ppm concentration, and were boiled for 30 min for complete dissolution. The final pH was adjusted to the desired value with acetic glacial acid or sodium hydroxide. These solutions were also prepared containing one of the industrial dyeing auxiliary agents, glacial acetic acid or trisodium phosphate; the simulated wastewater prepared contained both products.

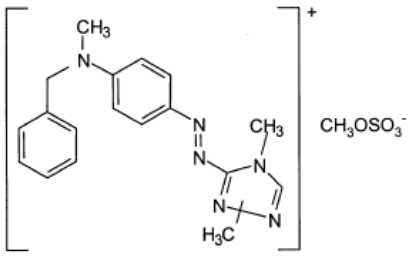

Figure 1 Chemical structure of Astrazon Red FBL 200% - C.I. Basic Red 46 (Martin et al., 2003)

2.2 Adsorbent preparation

The almond hulls were ground and sieved. All experiments were performed with particles of grain size between 0.710 and 1.190 mm.

2.3 Equilibrium batch studies

The equilibrium adsorption isotherms were determined, at 20 and 41ºC, using an orbital P-Selecta Rotabit shaker into a refrigerated incubator P-Selecta Hotcold-M. A set of 100 mL erlenmeyers (with cap) containing 50 mL of dyestuff solution and different amounts of adsorbent were shaken at 100 rpm during 13 days, contact time necessary to reach equilibrium. A blank test was run, at the same conditions.

At the end, the adsorbent was separated using a Centrifuge Sartorius, Sigma 2-16. The dyestuff concentration of each sample was obtained by measuring its absorbance in a Jenway 6100 spectrophotometer at the maximum absorbance wavelength (525 nm). Initial and pH final values were also evaluated using a Metro HM-632 meter.

2.4 Kinetic studies

The kinetic experiments were performed in a batch continuously stirred vessel (1.2 L) with 4 g of adsorbent, at 20ºC. The shaft stirring rate was 400 rpm. The 3 mL samples were

collected using a syringe, allowing the determination of the dyestuff concentration and pH histories.

3 Results and discussion

Adsorption isotherms were determined at different pH and temperature and the influence of the presence of some auxiliary dyeing agents was also evaluated. Both Langmuir and Freundlich models can fit the experimental results and the model parameters can be consulted in tables 1 and 2, respectively, together with the experimental conditions. Freundlich constant, n, is always greater than 1, indicating favourable adsorption.

To study the influence of temperature, isotherms at 20 and 41ºC (experiments 1 and 2), and pH 6, were performed. The experimental results and their Langmuir and Freundlich fits are shown in figure 2. Comparing the Langmuir maximum adsorption capacities, presented in table 1, it is observed an increase with temperature, from 15±3 to 30±11 mg/g, respectively. This increase might be explained (Asfour *et al.*, 1985) by an increase of pore size diameter due to the swelling of the almond hulls caused by heating at 41ºC, allowing the dyestuff molecules to penetrate further in the adsorbent pore structure than at 20ºC.

Table 1 Experimental conditions and Langmuir model [$q = q_s.k_L.C/(1+k_L.C)$] parameters, respective confidence intervals, square correlation to model (r^2) and variance (s^2) for each experiment.

Experiment	pH initial	pH final	T (ºC)	q_s (mg/g)	k_L (L/g)	r^2	s^2
1	6.09	6.85	20	15±3	0.31±0.14	0.979	$3.42x10^{-7}$
2	6.04	6.49	41	30±11	0.084±0.047	0.986	$3.09x10^{-7}$
3	9.05	7.31	20	16±6	0.18±0.13	0.943	$6.96x10^{-7}$
4	4.5	6.52	20	13±3	0.199±0.100	0.979	$2.33x10^{-7}$
5	4.95	5.39	20	23±26	0.033±0.054	0.896	$9.35x10^{-7}$

Table 2 Experimental conditions and Freundlich model [$q = k_F.C^{(1/n)}$] parameters, respective confidence intervals, square correlation to model (r^2) and variance (s^2) for each experiment.

Experiment	pH initial	pH final	T (ºC)	k_F $(mg/g)(L/g)^{1/n}$	n	r^2	s^2
1	6.09	6.85	20	3.7±0.6	2.13±0.38	0.982	$2.90x10^{-7}$
2	6.04	6.49	41	2.7±0.7	1.43±0.25	0.983	$4.05x10^{-7}$
3	9.05	7.31	20	2.9±0.7	1.88±0.40	0.971	$3.36x10^{-7}$
4	4.5	6.52	20	2.6±0.3	2.03±0.23	0.993	$6.79x10^{-8}$
5	4.95	5.39	20	1.0±0.8	1.34±0.57	0.886	$1.02x10^{-6}$

To evaluate the influence of pH, isotherms at three different initial pH values, 4.5 (adjusted with acetic glacial acid, an auxiliary dyeing agent), 6 and 9 (adjusted with sodium hydroxide), at 20ºC, were performed (experiments 4, 1 and 3, respectively). The experimental results and the Langmuir and Freundlich model adjusts are presented in figure 3. Comparing the Langmuir maximum adsorption capacities, in table 1, there is an intersection of confidence intervals, indicating no significant effect of pH, which could be related to the fact that final pH

was almost the same in both cases, ranging from 6.5 to 7.3. The buffer effect observed might be related with acid-base reactions with substances leached by the almond hulls.

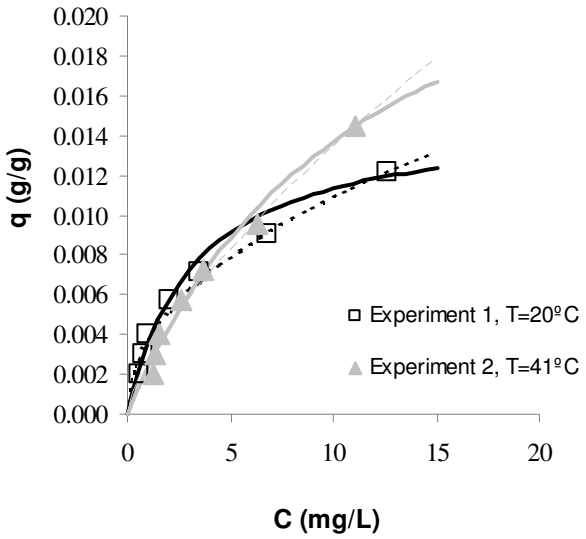

Figure 2 Experimental equilibrium isotherms, at 20 and 41ºC, and respective fits to Langmuir (continuous lines) and Freundlich models (dashed lines).

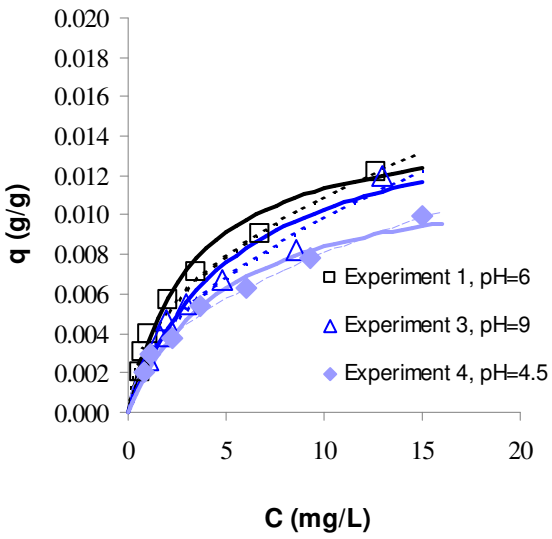

Figure 3 Experimental equilibrium isotherms, at different initial pH values, and respective fits to Langmuir (continuous lines) and Freundlich models (dashed lines).

In order to approach real situations, isotherms were also performed with a simulated effluent (experiment 5), containing acetic glacial acid, used for acidification to a 5 pH, and 0.5 g/L of trisodium phosphate. These auxiliary dyeing agents are always used for dyeing acrylic fibres and their concentrations belong the range of typical values. Usually acetic acid is added to the dye bath to help the take up of the dye onto the fibre. The salt is used as an electrolyte and has also a buffer effect in the dyeing bath. Consequently the final pH of this experiment, 5.4, was similar to the initial value.

The experimental results obtained with this simulated wastewater and respective Langmuir and Freundlich adjusts were compared with the ones obtained for the dyestuff solution without addition of other chemicals (experiment 1) and with the dyestuff solution prepared with glacial acetic acid (experiment 4), as auxiliary dyeing agent, in figure 4. A reduction of adsorption is observed when the dyestuff solution complexity increases, as it was expected however this is not clear due to the results dispersion in experiment 5 caused by the growth of microrganisms (detected visually). The presence of organic matter, nitrogen (present in the dyestuff) and phosphorus (present as trisodium phosphate) at moderate pH, gave rise to the development of microrganisms along the 13 days of contact time. The simultaneous occurrence of biological degradation and adsorption are considered advantageous (Figueiredo *et al.*, 2000), allowing longer operation times that delay, or avoid, the replacement of the spent adsorbent.

Although equilibrium studies are important to known the maximum amount that can be removed by a given material, the kinetic of the process limits the rate at which equilibrium state can be reached, what is usually the critical point in operation conditions.

A kinetic study was also performed with the same synthetic wastewater of experiment 5, at 20ºC, and 400 rpm shaft stirring rate. Under these conditions equilibrium was reached after 120 min and the experience lasted for 180 min. This period of time is smaller than the equilibrium time used for isotherms determination because agitation rate is higher. It was not enough to allow microrganisms growth, so the equilibrium adsorption isotherm obtained with simultaneous biogradation was consider no longer valid.

Pseudo-first order and pseudo-second order models were adjusted to the experimental results and are presented in figure 5; the adjusted parameters are shown in table 3. The best fit was obtained for pseudo-second order model, using a experimental equilibrium concentration of 2.44 mg/g in the solid phase and a 80 ±14 g/(g min) kinetic constant. If the equilibrium concentration in the solid phase was calculated using the Langmuir Model (the best model fit obtained) a 10.4 mg/g value would be obtained, indicating that there was a strong contribution of biodegration (77%) to the dyestuff removal from the synthetic textile wastewater.

Pseudo-second order kinetics are often verified for biomaterials, namely in agricultural wastes (Mckay and Ho, 1999). The model parameters obtained can be used for comparison with different systems or different experimental conditions.

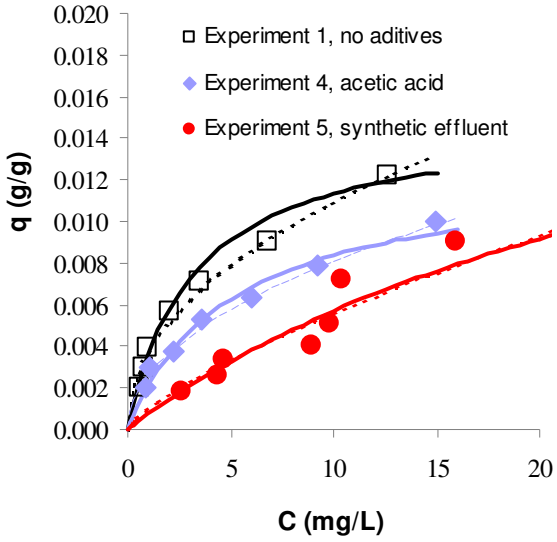

Figure 4 Experimental equilibrium isotherms for different compositions of dyestuff solution and respective fits to Langmuir (continuous lines) and Freundlich models (dashed lines).

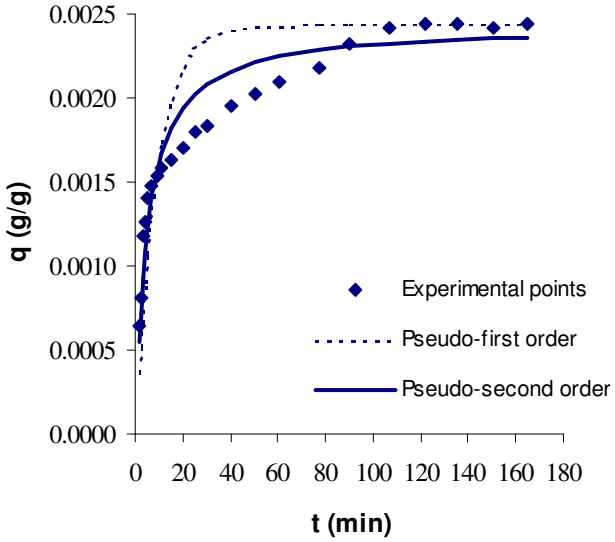

Figure 5 Experimental points of the kinetic study and pseudo-first and pseudo-second order model fits.

Table 3 Experimental conditions, pseudo-first and pseudo-second order model parameters, kinetic constants (k) and experimental equilibrium solid phase (q_e), respective confidance intervals, square correlation to model (r^2) and variance (s^2).

Model	pH initial	pH final	T (ºC)	k	q_e (mg/g)	r^2	s^2
Pseudo-first order	4.95	5.39	20	0.11±0.03	2.44	0.862	9.92×10^{-8}
Pseudo-second order	4.95	5.39	20	80±14	2.44	0.934	2.42×10^{-8}

Although the equilibrium capacities of almond hulls are much lower than those obtained for activated carbon for basic dyes (El Qada et al., 2008) the cost of this industrial adsorbent is also much higher. Besides the valorization of almond huks, an easy available waste, the material shows a significative uptake of dyestuff.

This affinity can be attributed (Mckay et al, 1987; Laszlo and Dintzis, 1994) to the columbic interaction of the cellulosic surface, negatively charged in aqueous solution, with cationic species, like the basic dyestuff studied. However there are still ways of improving the

performances of this adsorbent, such as by chemical treating of the natural material (Gong *et al*., 2005).

4 Conclusions

Almond hulls, a natural waste are easily available, were tested in order to remove the basic dyestuff Red Astrazon FBL 200% (CI basic red 46), from Dystar.

The kinetic experiments were well described by the pseudo-second order model. Langmuir or Freundlich models can fit equilibrium batch studies. The equilibrium results show a slight influence of temperature, indicating that adsorption is rather favoured at 41 than at 20ºC. The pH influence was not significant under testing conditions.

The increase of complexity of the dyeing solution decreased the dyestuff removal. However, the presence of auxiliary dyeing agents, as occurs in a real effluent, gave rise to the development of microrganisms along the 13 days of contact time. The simultaneous occurrence of biological degradation and adsorption are considered advantageous (Figueiredo *et al*., 2000), allowing longer operation times that delay, or avoid, the replacement of the spent adsorbent. The results obtained suggest a possible application of almond hulls, a cost effective solution that may contribute to the sustainability of the environment.

Keywords: delignification effluent; fungus treatment; combined processes; alginate beads
Topic: Integration of life sciences & engineering

Abstract

The aim of this work was to characterize the delignification effluent from nitrocellulose industry, evaluate the activity of immobilized catalyst (TiO_2) in alginate beads for photocatalysis and evaluate the combination of fungus treatment and photocatalytic treatment (catalyst immobilized in Ca-alginate beads), for the treatment of this effluent. The delignification effluent has proven harmful to the environment because it presents high color (3516 CU), total phenol (876 mg/L) and TOC (1599 mg/L) and also highly toxic even at in low concentration. The results of photocatlysis with catalyst were 11, 25 and 13 % higher for reductions in color, total phenol and TOC, respectively than the parallel processes (photolysis + adsorption). The combined treatments presented benefits when compared to the non-combined ones. Fungus and photocatalysis in combination showed to be the best treatment, reducing the color, total phenol, toxicity (inhibition of Escherichia coli growth) and TOC by 99.5 %, 95.4%, 64% and 56 %, respectively.

1 Introduction

During the production of nitrocellulose, an important polymer for the inks, lac and explosives industries, effluents are also produced. Delignification effluent results from the alkaline treatment of cotton fibers. This effluent has dark color, a large amount of organic matter and is highly toxic (Paiva *et al*., 2001; Tran *et al*., 2006).

Since 1977, several studies or the treatment of effluents originating from the cellulose industry have indicated fungi as an alternative method. This is because fungi are able not only metabolize lignin and its derivatives, but also reduce the effluent's color, organic matter and toxicity (Malaviya *et al*., 2007; Souza *et al*., 2005; Rao *et al*., 2006).

Heterogeneous photocatalysis is based on the activation of semicondutor material by solar or artificial light. The literature shows several works employing immobilized catalyst since this technique allows the catalyst recovery after the reaction and also operation in a continuous mode (Peralta-Zamora et al., 1998; Silva *et al*., 2002).

The use of integrated processes could be a promising alternative for the treatment of these kind of effluents. This kind of combination process is attractive for cellulose industry effluents, since the photocatalytic process could be employed in the biological process for the degradation of recalcitrant, toxic and inhibitory compounds, increasing the effluent biodegradability. On the other hand, the biological process, when employed as a pre-treatment, could remove the biodegradable fraction, decreasing this way the use of energy and reagents in the photocatalysis process (Oller et al., 2007; Bandala et al., 2008; Pedroza *et al*., 2007; Beek *et al*., 2007).

The aim of this work was to characterize the delignification effluent from nitrocellulose industry, evaluate the activity of immobilized catalyst in alginate beads for photocatalysis and evaluate the combination of fungus treatment and photocatalytic treatments, as a possible effluent treatment.

2 Material and methods

2.1 Effluent characterization

Delignification effluent: All the experiments were carried out employing a delignification effluent originating from the alkaline pulping (NaOH) of the nitrocellulose producted by an industry that uses cotton as the raw material. The original pH value of the cotton delignification effluent was adjusted to five and the effluent was always diluted 10 times before it was used in the treatment tests.

Color measurement: Color was measurement as described by CPPA (1975). In all cases the effluent were previously centrifuged at 3.500 rpm for 5 minutes.

Total phenol: Total phenol was measured following the standard procedures described by APHA (1989).

Total organic carbon (TOC): Total organic carbon was measured according to the standard procedures described by ISO (1987).

Acute toxicity test: The effluent acute toxicity test was carried out by determining the growth inhibition of *Escherichia coli*, modifying a method previously described by Jardim *et al*., (1990). *E. coli* cultures were contaminated with different concentrations of effluent and their growth was quantified using spectrophotometry (400 nm).

2.2 Reactor system

The photocatalytic reactor used in this study has a 9.5 cm^{-1} diameter cylinder (250 mL working volume). The irradiation in the photoreactor was obtained using 125 W (λ= 254 nm) low pressure Phillips mercury lamp (without the glass cover), positioned inside the reactor. The temperature was controlled by water circulation through the annular jacket surrounding the reaction zone. During the irradiation, the solution was magnetically stirred to ensure proper mixing and air was bubbled at an air flow rate of 90 mL/min.

2.3 Catalyst free and immobilization in alginate beads

Catalyst free: A TiO_2 Degussa P25 catalyst provided by Degussa Company was used throughout this work without further modification. It has the following main physical characteristics: BET surface area 55 $\pm$ 15 $m^2.g^{-1}$, average primary particle size around 30 nm, purity above 97% and with 80:20 anatase to rutile.

Catalyst immobilization: A 3% w/v solution of alginate was employed as support, and TiO_2 was added in the ratio of 10 g/L of gel. The catalyst beads, about 2 mm in diameter, were produced in a syringe, which was used to drip this mixture into a stirred solution of $CaCl_2$ (2%) at 4^oC. Afterward, the beads were stored in $CaCl_2$ solution during 24 h for stabilization.

Photolysis/adsorption: The photocatalytic activity of the immobilized catalyst in the alginate beads was evaluated by an experiment using catalyst without catalytic activity (TiO_2 ink industry - amorphous). A total of 10 g of immobilized catalyst per 100 mL of effluent was used and the irradiation time was 120 min. The TiO_2 concentration in the beads was of 0,1g (w/w).

2.4 Treatments

2.4.1 Fungus treatment

The fungus used in this work was isolated from activated sludge and identified as *Aspergillus* 2BNL1. This strain was selected after screening a group of fungi for their ability to decolorize delignification effluent. *Aspergillus* 2BNL1 was grown in Potato Dextrose Agar (PDA) medium in Petri dishes for 72 h at 28 ^{o}C and the spores were then suspended in sterile water, as described by Souza *et al*. (2002). Each flask (1000 mL) containing 250 mL of culture medium was inoculated with $1x10^5$ spores/mL culture medium (Malt Broth - MB). After 72 h, the pre-inoculum medium was filtered and the fungus biomass (20g) was transferred to 250 mL of the diluted delignification effluent (10 %, v/v), pH 5, without extra carbon source, and the effluent was treated for 24 h.

2.4.2 Photocatalytic treatment

A total of 100 mg of free anatase TiO_2 were added to 250 mL of effluent in reactor equipped with water refrigeration and magnetic stirrer, as described in items 2.2.1. The water evaporation was corrected by restoring the initial volume with distilled water. These conditions were previously optimized for Peralta-Zamora (1998) for the treatment of black liquor of a paper and cellulose Industry.

3 Results and discussion

3.1 Effluent characterization

The effluent presented a deep and even diluted color (3516 CU). This value is very high and if this effluent was released into the environment, even at low concentrations, it would impede light from penetrating the water, hindering the algae photosynthesis and consequently damaging the aquatic environment.

The total phenol content was 59.2 mg/L. The literature correlates the presence of compounds quantified by the Folin-Ciocalteus reagent with the effluent color (CPPA, 2007; APHA, 1989) and with the depolymerization of high molecular mass lignin derivatives.

The TOC content of the delignification effluent was 1599 mg/L. This TOC value is three times higher than that of domestic wastewater (Chan, 2004). The release of this effluent into water can cause an increase consumption of dissolved oxygen, damaging the aquatic environment. However, the effluent recalcitrance and toxicity most likely present a more significant problem.

3.2 Activity of immobilized catalyst in photocatalysis

The photocatalityc activity is defined as the difference between the parallel processes (photolysis + adsorption) and the photocatalytic degradation process.

In order to evaluate the photocatalytic activity of the immobilized catalyst in the alginate beads two experiments were carried: one using catalyst with photocatalytic activity (TiO_2 – Degussa-P25) and another one employing the catalyst without photocatalytic activity (TiO_2 ink industry - amorphous). The results are shown in Table 1.

Table 1- Parameters for evaluation of the catalyst activity

	Color Reduction (%)	Total Phenol Reduction (%)	TOC Reduction (%)
Photocatalysis	94.4 ± 0.3	83 ± 1	16 ± 0.8
Photolysis + adsorption *	83.4 ± 0.4	58 ± 1	3 ± 0.3

*Alginate beads doped with TiO_2 (amorphous) without catalyst activity.

The photocatalityc activity improved the reductions of color, total phenol and TOC in 11, 25 and 13 % respectively, that the immobilized catalyst was effective in its.

It is important to observe that the parallel processes of photolysis and adsorption were significant (mainly for the parameters of color and total phenol reductions), but contributed to the global process of photocatalytic degradation. The alginate beads doped with TiO_2 gather physical properties (absorption and adsorption) and chemistries (photocatalytic degradation) that can contribute in a combined way to the effluent purification.

Another important issue that should be investigated is the possible increase in TOC due to the degradation of the alginate support. This degradation is expected and the viability of the use of alginate as the support depends on the degradation rate of the substrate (effluent) in relation to the alginate degradation, that should be as highest as possible.

COMBINED AND NON-COMBINED TREATMENTS

The major problems presented by the delignification effluent are the color and the presence of lignin-derived phenolic compounds.

All the treatments reduced the effluent color significantly (86-99 %). The best treatment was the combination of fungus and photocatalysis treatment. This result can be explained by the increased efficiency of the photocatalytic treatment due to the reduction in chromophore compounds caused by the fungus treatment. Photocatalytic treatments were more efficient for the effluents with low color due to the increased transmittance and photonic efficiency (Tariq *et al*., 2008). This same explanation can be used to justify the other positive results obtained through this association.

A correlation between color reduction and total phenol concentrations was observed (r^2 = 0.9979). This same result was previously reported by Souza *et al*. (2004) and demonstrates that there was a correlation between the compounds quantified by the Folin-Ciocalteu reagent and the chromophores present in the effluent. The best treatment for this parameter once again was the combination of Fungus treatment and Photocatalysis treatment (95 %reduction).

The TOC reduction after the combined and non-combined treatments was studied. The photocatalytic treatment reduced TOC by 16 % while fungal treatment reduced it by 10 %. This low efficiency of the photocatalysis and fungal treatment in terms of reducing organic matter was justified by the high medium opacity and TOC content.

The combined treatments showed an increased reduction of organic matter in relation to the non-combined ones. The reductions revealed a high synergic effect of the combined treatments. In this context, the fungus + photocatalysis combination was more efficient (56%) than the photocatalysis + fungus combination (46%). Possible explanations for these results could be related to the following factors: 1-Phototratability elevation for the reduction in organic matter and opacity of the medium, increasing the photonic efficiency; 2-Reduction in the recalcitrant compounds, for the fungus biodegradation, after the photocatalytic treatment.

The untreated effluent, even at low concentrations, presented high toxicity, inhibiting 70% of *E. coli* growth (20 h) at the concentration of 5% (v/v).

All the treatments reduced the inhibition caused by the untreated effluent. The best non-combined treatment was Photocatalysis (19 % inhibition) and the best combined treatment was fungus + photocatalysis (6.7 % inhibition). In general, the treatments in which photocatalysis was sole or the last treatment applied produced results.

4 Conclusion

The delignification effluent has proven harmful to the environment because it presents high color, total phenol and TOC and is also highly toxic even in low concentration.

The results of photocatlysis with catalyst were higher for reductions in color, total phenol and TOC, than the parallel effects (photolysis and absorption).

The combined treatments presented benefits when compared with the non-combined ones. Fungus in combination with photocatalysis proved to be the best treatment, reducing color, total phenol, toxicity and TOC.

Topic: Sustainable process-product development trough green chemistry

Abstract

Olive Mill Wastewaters (OMW) are known by the recalcitrant character to biological treatments, therefore, with the aim to find technological solutions for the environmental problems related with the OMW, the efficiency of two chemical oxidations systems was tested. The effect of the main operating parameters in Fenton's process (pH, hydrogen peroxide concentration and iron concentration) was analysed. This process showed high efficiency for the degradation of the effluent phenolic content for all the conditions in use. The highest COD removal was 78.5%. Ozonation revealed higher difficulty in COD degradation with 17.6% removal after 180 min for the best conditions tested (high ozone inlet gas concentration and acidic pH). The effect of ozone gas inlet concentration and pH in the process efficiency was investigated. Moreover, preliminary results showed the efficiency of ultrafiltration, a refining treatment of OMW subjected to Fenton's process followed by ozonation.

1 Introduction

Sustainable development is related with a good management of the effluents produced during the industrial processes. In general, the agro-industries are characterized by small familiar companies spread all over the country where the management and depuration of the final effluents is not usually efficient. Nevertheless, the growing public concern around environmental problems related to the disposal of such wastewaters brought up more restrictive legislation that is being progressively applied. In this context, the operation license of the companies is dependent on the environmental certificate which implies the use of adequate wastewater treatment technologies.

Mediterranean Sea area countries are the world main producers of olive oil with an estimated production volume of 2.5 millions of ton correspondent to almost 98% of the global production. Within this scenario, Olive Mill Wastewaters (OMW) are of special concern to these countries. It is estimated that each year 30 million m^3 of olive mill effluents are produced. Even if the characteristics of those wastewaters vary widely with regard to the oil extraction method and the region, the following general characteristics can be attributed: dark brown to black colour; strong smell; high organic content; low biodegradability; acidic character; high concentration in phenolic compounds and high solid content (Azbar *et al.*, 2004).

Due to the presence of several toxic compounds (as is the case of phenolic substances) allied with the seasonal character of these effluents, since the mills only operate during a few months each year (normally the olives collection and oil extraction only takes place during the winter months, starting in November and finishing in February), the application of the

* Corresponding author. Tel + 351-239-798723. E-mail:rosaqf@eq.uc.pt (R. M. Quinta-Ferreira), martins@eq.uc.pt (R. C. Martins)

traditional active sludges treatment leads to inefficient depuration levels. Therefore, alternative methods have to be tested and implemented to minimize the ambient impact and/or allow to water recycling in the olive oil production. In this context, the application of physico-chemical processes appears to be a suitable alternative, which may have higher implementation and operational costs when compared with the traditional biological processes. Nevertheless, the application of integrated systems involving several treatment processes seems to be a suitable alternative concerning both organic content degradation and operational costs. Some studies involving physico-chemical and/or biological treatment processes integration for the depuration of OMW are found in the literature. Gomec *et al.* (2007) used Fenton process to treat OMW after acid cracking, polyelectrolyte and lime flocculation obtaining a final Chemical Oxygen Demand (COD) < 2000 mgO_2/L. Bedoui *et al.* (2008) achieved almost 90% of COD removal using UV radiation coupled with hydrogen peroxide. Andreozzi *et al.* (2008) concluded that, even for long experimental times, the different combinations between centrifugation, ozonation, solar photolysis and photo Fenton were only able to lead to a maximum of 74.7% of COD removal. Photo-Fenton process reduced the effluent toxicity allowing to a more efficiency pos-anaerobic digestion (Khoufi *et al.*, 2007). Also ozonation coupled with anaerobic treatment showed good results in OMW depuration (Beltran-Heredia and Garcia, 2005). Some work was done in the application of ultrafiltration for the treatment of OMW. Akdemir and Ozer (2008) used a Box-Wilson statistical experiment design method to optimize the operational condition of an ultrafiltration unit in a raw OMW. Turano *et al.* (2002) integrated centrifugation with ultrafiltration while Drouiche *et al.* (2004) tested the applicability of an oxidant system UV/H_2O_2 to finish the treatment of the permeate after the ultrafiltration process. The aim of this research is to study the efficiency of the combination of the oxidation processes Fenton and ozonation and the separation technique in the treatment of OMW in order to achieve an effluent suitable to be discharged in municipal wastewater treatment plants. In Fenton process the oxidant power of hydrogen peroxide is enhanced by the presence of the iron catalyst, whereas ozonation is based on the oxidant ability of ozone which reacts quickly with high electronic density molecules as phenolic compounds. The ultrafiltration is a membrane process suitable for separating dissolved macromolecules in solution on the basis of size and is usually used as a refining process of the other treatment technologies.

2 Experimental

The effluent from the olive oil extraction was collected during the month of February from a mill in the Extremadura region of Spain.

2.1 Experimental Procedure

2.1.1 Fenton process

The tests involving the Fenton reagent were performed in a *Jarr-Test* unit provided with baffles paddles. The reactors were filled with 300 mL of effluent and the stirring speed was set at 200 rpm. $FeSO_4.H_2O$ was added as catalyst in a concentration range of 1520 – 15200 ppm on iron. Hydrogen peroxide was added in batch mode with a range of concentration between 7000 and 34000 ppm. When the influence of the initial pH was studied, a solution of H_2SO_4 was used. Samples were periodically withdrawn (3 mL) and the reaction stopped by the addition of NaOH (1.75 M), for further analysis. The iron sludge formed was removed by filtration before the application of the several analytical procedures.

2.1.2 Ozonation

Ozonation was performed in a semi-batch glass reactor (500 mL) provided with two gas diffusers as described elsewhere (Martins *et al.*, 2008). Ozone was generated in a 802N BMT ozone generator by means of an oxygen stream (500 cm^3/min). Ozone gas inlet concentration was set in the range 40-120 g/m^3 (BMT 963 vent BMT ozone gas analyzer). When the effect of pH was studied (In the study of the effect of pH on the process efficiency), a solution of NaOH (1.75 M) was used to set this parameter in the desired value. Samples were periodically withdrawn for analysis.

2.1.3 Ultrafiltration

In the ultrafiltration tests, which were operated in total recirculation mode, the effluent was stored in a stirred reservoir and pumped to a hollow fiber membrane module (Minikros, *Sepctrum*). The membrane studied had a molecular weight cut-off of 50 kDa and an area of 400 cm^2. Two manometers, one before and other after the module ~~membrane~~ allowed to measure and control the pressure drop in the module. The liquid flow was established by means of two valves and one rotameter. The liquid flow was first stabilized and along the experiments different pressure drops in the membrane were tested. Permeate samples were taken for analyses.

2.2 Analytical methods

Due to the wide variety of compounds present in OMW, it is useful to characterize the effluent in terms of lumped parameters, such as Total Organic Carbon (TOC), Chemical Oxygen Demand (COD), Biological Oxygen Demand (BOD) and Total Phenolic Content (TPh). TOC was measured in a *Shimadzu 5000 TOC* analyzer, which operates based on combustion/non-dispersive infrared gas analysis method (NDIR). COD was measured by the dichromate method; the samples were digested at 148ºC in a *WTW CR3000* thermoreactor and COD measured in a *WTW MPM3000* photometer. BOD after 5 days (BOD_5) was obtained by the method described in the Standard Methods (1985) measuring the dissolved oxygen (*Multi-parameter Analyser CONSORT C863*) before and after 5 days of incubation of a population of microorganisms obtained from a garden soil suspension. TPh was determined using a Folin-Ciocalteau reagent in a *T60 U PG instruments* spectrophotometer by the procedure described elsewhere (Martins *et al.*, 2008). Total Suspended Solids (TSS) and Total Dissolved Solids (TDS) were determined according to the Standard Methods (1985).

3 Results and discussion

In this section the effluent characterization is firstly presented. The laboratorial results addressing Fenton's process and ozonation are then discussed and afterwards the application of ultrafiltration as refining process to an Olive Mill Wastewater treated by Fenton followed by ozonation in an industrial unit is analysed.

3.1 Effluent Characterization

The effluent characterization was mainly performed in terms of the lumped parameters shown in Table 1.

Table 1. Characterization of industrial effluent

pH	TOC (mgC/L)	COD (mgO_2/L)	BOD5 (mgO_2/L)	BOD5/COD	TPh (mgeq. gallic acid/L)	TSS (mg/L)	TDS (mg/L)
4.7	368±23	1485±15	216±24	0.14	106.4±5	40	1160

The effluent shows acidic character (pH=4.7) typical of OMW, yet the organic content of the wastewater, measured as TOC, COD or BOD_5, is low when compared with the range of values present in the literature (Azbar *et al.*, 2004). Nevertheless, this sample had already suffered sedimentation which explains also the low TSS value and also the wastewater results from the mixture of the process effluent with the washing waters. A ratio between BOD_5 and COD lower than 0.3 means an effluent with low biodegradability (Farré *et al.*, 2007). This was expected since OMW is known by the presence of several organic compounds toxic to the microorganims as is the case of phenolic substances here quantified by the equivalent gallic acid concentration (106.4 mgeq. gallic acid/L). These substances are usually quickly removed by chemical oxidation processes and therefore the applicability of Fenton reagent and ozonation was tested.

3.2 Fenton stage

The Fenton process is based in the oxidant power of hydroxyl radicals produced by the catalytic decomposition of hydrogen peroxide in the presence of iron at acidic conditions. The influence of the operating parameters, hydrogen peroxide initial concentration, ferrous iron initial concentration and pH was investigated. Figure 1a despites the COD normalized concentration during the Fenton experiments. In all the experiments, a high COD decrease occurred for the first minutes of reaction followed by a lag period with low oxidation rates. The increase in the initial concentration of H_2O_2 from 7000 to 34000 ppm largely improved the process efficiency with COD removal increasing from 52.5% to 78.5%. The growth in H_2O_2 concentration leads to the formation of more hydroxyl radicals enhancing oxidation, while an excess of this reactant in solution may also act as radical scavenger which reduces the process performance (Ahmadi *et al.*, 2005). Also the increase of the initial iron concentration from 1520 to 15200 ppm (with all the other variables constant) improves the process efficiency in terms of COD removal in 16% after 120 min of reaction. Nevertheless, the impact of this variable is not as important as the hydrogen peroxide initial concentration. In fact, from an optimization process based on an experiment design and response surface methodology (results not shown) it was concluded that among the process parameters tested only H_2O_2 initial concentration had statistical relevance for the treatment efficiency in terms of COD removal. The Fenton's process efficiency is highly affected by pH, being generally acidic media (pH between 2 and 4) more favourable (Rivas *et al.*, 2001). In our studies, COD removal increased when pH increased from 2.5 to 4.7 (62.3% and 78.5%, respectively). Nevertheless, it should be pointed out that the pH suffered a quick self adjustment to 2.8 after the reactants introduction, regardless the initial value. Due to the effluent toxicity related with the phenolic content it is important to evaluate the efficiency of the treatment technology on the removal of these compounds. For every experimental conditions tested, total phenolic degradation was achieved in the early minutes of reaction.

3.3 Ozonation stage

The effect of pH and ozone inlet gas concentration was tested in the efficiency of ozonation process for the treatment of OMW. The first observation taken from the results in Figure 2 is that ozonation leads to lower COD removal efficiency than the Fenton's process for all the experimental conditions under study.

The increase of ozone inlet gas concentration (for the same pH value) from 40 g/m^3 to 120 g/m^3 allowed higher degradation levels with COD removal raising from 10.6% to 17.6%. This was expectable, since a higher amount of ozone was available for reaction. pH is an important parameter in aqueous ozone chemistry since it controls the oxidant double action. At low pH values ozone attacks selectively organic molecules characterized by high electronic density. For alkaline pH values ozone is decomposed into highly reactive hydroxyl radicals, which will correspond in general to a higher depuration level. Nevertheless, comparing the results achieved for the experiments conducted at pH = 3.4 and 9.2 (for the same inlet ozone gas concentration of 120 g/m^3), one can observe a decrease in ozonation efficiency with the increase of pH with COD removal of 17.6% and 8.8%, respectively. In fact, in real wastewaters the presence of inorganic compounds, like carbonates that act as radical scavengers may interfere with the treatment, which can explain the decrease in the degradation for the experiment with alkaline pH.

3.4 Ultrafiltration process for Fenton – Ozonation pre-treated effluent

Within the previous results for the individual Fenton and Ozonation treatments of OMW, the applicability of Ultrafiltration as refining process for an effluent previously submitted to Fenton followed by ozonation in an industrial plant was examined. The pre-treated OMW was characterized by a COD value of 883 mgO_2/L. The effect of the operating variables (feed flow rate and pressure drop) on the ~~(~~COD removal efficiency and permeate flux - J is given in Figure 2. As expected, J shows a linear behaviour with the transmembrane pressure (Figure 2a). Moreover, for a constant pressure, J increases with the recycling flow rate. In fact, higher cross-flow velocity results in the increasing of the transport of the solutes from the membrane surface to the bulk feed; therefore the concentration polarization is reduced which

increases the permeate flux (Akdemir and Ozer, 2008). As observed in Figure 2b, COD removal in ultrafiltration process is in the range of 11.1% and 31.5%. Contrarily to what was expected, the increase of the COD removal efficiency increased with the recycling flow rate for constant pressure, for example for 0.5 bar COD reduction changes from 31.5% to 11.1% for the cross-flow rate of 0.12 and 0.06 m/s, respectively. It should be also noticed that, while for higher cross-flow rates (0.12 and 0.09 m/s) COD removal is almost constant with transmembrane pressure, for the lowest cross-flow rate the efficiency decays with pressure. These phenomena can be attributed to the fact that the fouling layer was not totally formed and, therefore steady state was not reached yet.

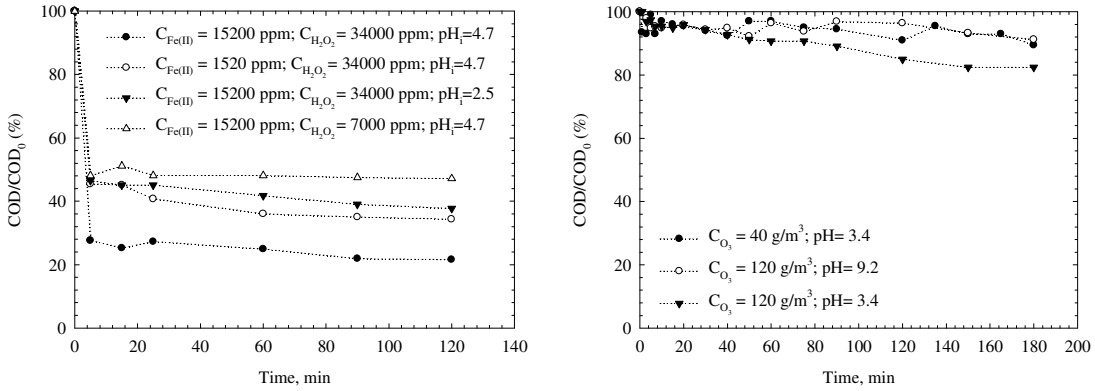

Figure 1. COD removal along **a)** Fenton's process at several experimental conditions and **b)** ozonation.

Figure 1. Evolution of the COD removal at different experimental conditions: a) Fenton treatment and b) Ozonation process.

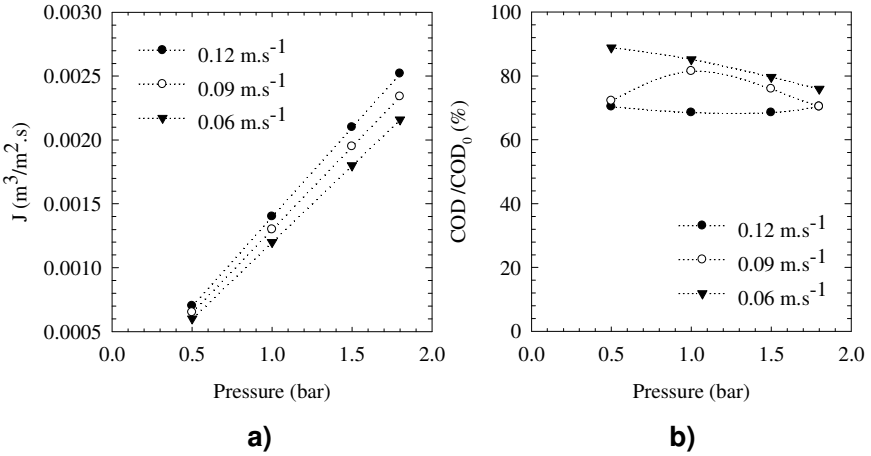

Figure 2. Permeate flux (a) and COD removal (b) as function of the transmembrane pressure at different recirculation velocities.

4 Conclusions

OMW constitutes a major environmental problem due to the bio-refractory character and seasonability. Therefore it is a technological issue of main importance the finding of suitable technologies to safely treat these effluents. Within this objective, the chemical oxidation by Fenton's reagent and ozonation were tested for the depuration of a real OMW. Fenton's process efficiency was on the range of 52.5 and 78.5% of COD removal depending on the

operating conditions (initial pH, concentration on hydrogen peroxide and iron). Among those operational variables the main effect on the process efficiency was caused by the concentration on hydrogen peroxide with an improvement of 26% on COD degradation when this value rises from 7000 to 34000 ppm. Ozonation showed lower efficiency in the mineralization of this effluent, with COD removals between 8.8 and 17.6%. The increase on ozone inlet gas concentration improved the process whereas the increase of the pH reduced the treatment efficiency probably due to the presence of inorganic radical scavenger on the effluent composition. Preliminary tests involving ultrafiltration of a pre-treated OMW by Fenton's reagent followed by ozonation on an industrial plant enhanced the applicability of this physical separation process as a refining treatment on OMW depuration. Within our results, ultrafiltration led to colourless effluent and for the best experimental conditions reduced 31.5% of the COD.

Topic: Sustainable process-product development through green chemistry – Environmental engineering & management

Abstract

In the present work, formaldehyde, which left in phenolic resin plant effluent after removal of phenol, has been treated with hydrogen peroxide in alkaline medium and also in acidic medium (Fenton process). In alkaline medium, formaldehyde was oxidized with hydrogen peroxide to formate ion, which was tried to recover by liquid-liquid extraction. The oxidation of formaldehyde with Fenton process was also studied under different initial pH, mole ratio of hydrogen peroxide to formaldehyde, pressure and temperature. It was found that ratio H_2O_2:HCHO 7 provided 97% removal of total organic carbon (TOC) after 2 h and larger amounts of H_2O_2 were necessary to mineralize around 90% HCHO in 1 h, at atmospheric pressure and 25 ºC. The combination of pressure and high temperature strongly increased the kinetics of the process.

1 Introduction

Phenol and formaldehyde are the main pollutants discharged by phenolic resin producing industries. Since exposure of these chemicals has potential toxic effect on living being, these chemicals must be removed from effluent before releasing it in the environment. The usual treatments of phenolic effluent are biodegradation, thermal decomposition, extraction and adsorption [Kibret *et al.*, 2000; Mollah and Robinson, 1996; Yu and Savage 2000]. Among them, biological treatment is limited to only less concentrated phenolic effluent (< 3000 mg/L) [Kibret *et al.*, 2000] because microorganisms can not survive in higher concentration of organic compounds. On the other hand, thermal decomposition and adsorption proved high energy consuming and costly methods [Mollah and Robinson, 1996; Yu and Savage 2000]. But solvent extraction method finds some advantages in treating concentrated phenolic wastewater. This is justified with the work published in literature [Li *et al.*, 2004]. Our research group also studied the removal of C_6H_5OH and HCHO from phenolic resin plant effluents by using solvent extraction [Correia and Cravalho, 2005; Correia *et al.* 2007]. The studies revealed that Cyanex 923 was found more selective extractant for C_6H_5OH than other tested extractants and also extraction of formaldehyde (present in the solution with phenol) was almost nil. So the objective of the present work is to remove formaldehyde after the separation of phenol. In literature, several methods are cited to obtain this objective like liquid-liquid extraction, polymerization with urea, oxidation in alkaline medium, oxidation in acidic medium (Fenton process), photo-Fenton process, treatment with active charcoal and conversion to easily biodegradable formaldehyde disulfide.

The liquid-liquid extraction of formaldehyde with 1-decanol was already tested [Correia *et al.*, 2007], but the kinetics of the extraction was very slow. Equilibrium was reached in more than 6 h. Therefore, oxidation of formaldehyde in alkaline and acidic medium (Fenton process) were studied and the results are presented here. In presence of base, formaldehyde was

* Corresponding author. Tel: +351 218417311. E-mail: jcarv@ist.utl.pt

oxidized with hydrogen peroxide to formate according to the following chemical equation (Walker, 1975).

$$2\ HCHO_{(aq)} + H_2O_{2\ (aq)} + 2\ NaOH_{(aq)} \longrightarrow 2\ NaHCOO_{(aq)} + 2H_2O_{(aq)} + H_{2(g)}$$

After oxidation, the resultant formate was acidified to formic acid. Further the recovery of formic acid was carried out by liquid-liquid extraction with Cyanex 923 and Alamine 336. In literature, some other works are also published related to formic acid extraction using phosphate containing extractants [Wisniewski and Pierzchalska, 2005; Cai et al., 2001] and tertiary amines [Hu and Adeyiga, 1997]. Also oxidation of formaldehyde with Fenton process in different experimental conditions were carried out and the results are discussed here.

2 Experimental

Formaldehyde oxidation studies

The experiments of chemical oxidation in alkaline medium were carried out at 22 °C using 130 Vol. hydrogen peroxide (José Manuel Gomes dos Santos LDA), sodium hydroxide (Panreac, p.a.) and potassium hydroxide (MERCK, p.a.). The experiments of chemical oxidation of formaldehyde, using Fenton reagent, at 25 °C, were carried out in 2 L Pyrex glass insulated reactor with agitation. This reactor could withstand 0.6 bar external pressure. The experiments with high temperature and under pressure were conducted in a 1.5 L stainless steel 316 AISI insulated reactor with agitation. It is coated with Hypalon and a high temperature of 200 °C and 15 bar pressure can be maintained in this reactor. pH was adjusted by using dilute sulphuric acid. Heptahydrated ferrous sulphate, $FeSO_4.7H_2O$ (MERCK, p.a.) was used as catalyst.

Liquid-liquid extraction studies

The organic phases were prepared by diluting the extractant in aliphatic diluents viz., Shellsol T (Shell Chemical Ltd.) and Exxsol D80 (ExxsonMobil, Spain). In the present study, the extractant Cyanex 923 was used as such as obtained from Cytec, Netherlands. Another extractant Alamine 336 (Cognis) was also tested but along with the modifier 1-decanol (Acros Organics, Belgium). Before use, Alamine 336 was washed with acidified water and then with water to remove impurities. 3 M NaOH was used to strip loaded formic acid.

Analytical methods

Formaldehyde analysis was done by the Hantzsch reaction colorimetric method [ASTM, 1999]. A double beam ultraviolet/visible spectrophotometer Hitachi U2000 was used for the analysis. Formate ion was analyzed by potentiometric titration in a Metrohm 682 Titroprocessor. Total organic carbon was determined by Dohrmann Carbon analyzer. pH was measured by a Metrohm 827 pH meter with a Metrohm combined electrode.

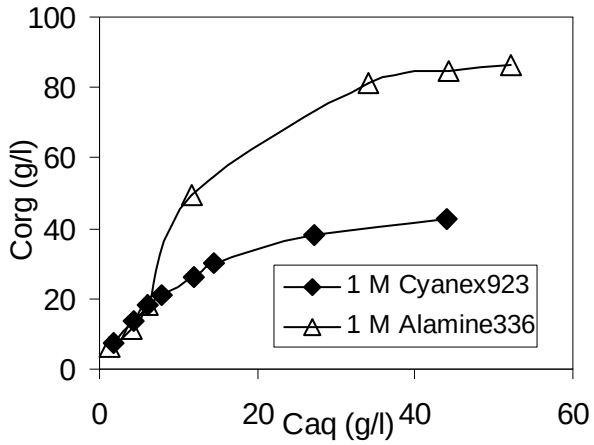
3 Results and discussion

Oxidation of formaldehyde in alkaline medium and recovery of formate

The phenolic effluent, after removal of phenol, contains mainly formaldehyde which was treated with hydrogen peroxide in alkaline medium. The concentration of formaldehyde oxidized, by hydrogen peroxide in presence of either KOH or NaOH, was 41 g/L. The results showed that reaction is independent of nature of base as nearly 100% stoichiometric conversion of formaldehyde to formate was obtained in both the cases. Further, kinetic study revealed that the reaction was over in less than 5 min.

The extraction of formate ion, obtained after oxidation, with tertiary amine and Cyanex 923 was tried but extraction was lower than 5%, so extraction of formate ion in the form of formic acid was tried. This is also supported by the work of Hu and Adeyiga [1997] who used CO_2 to convert formate to formic acid before extraction with tertiary amines. Since the oxidation was performed in alkaline medium, the pH of the resultant solution was as high as 12. Therefore, the resultant formate solution was first acidified with concentrated sulphuric acid and for that a reasonable amount of acid was used. To adjust the pH around 2.0 of the 1500 mL formate

solution, 60 mL concentrated sulphuric acid was required. This data shows that the removal of formaldehyde in the form of formic acid from waste water ought not to be very economical for industrial purpose. Nevertheless, bench scale studies were carried out to explore the potential of extraction and concentration. The extraction of formic acid with Alamine 336 has been already studied by our research group [Correia *et al.*, 2005]. In those studies Alamine 336 was protonated before using it for extraction of formic acid. Here two extractants i.e. Cyanex 923 and Alamine 336 again but in unprotonated form are used. The preliminary experiments of extraction of formic acid using Cyanex 923 with diluents Shellsol T and Exxsol D80 were carried out at 25 ºC. The results showed that extractive performance of Cyanex 923 remained almost the same with both diluents. Shellsol T was used as diluent in all the subsequent studies. The extraction of 61 g/L formic acid was then tried with 0.6 M and 1.0 M Cyanex 923 and the extraction capacity increases with the increase in concentration of extractant as also obtained with Alamine 336. In case of extraction with Alamine 336, 10% 1-decanol was used as modifier. The equilibrium curve for the extraction of 61 g/L formic acid solution with 1.0 M Cyanex 923 was compared with that obtained with 1.0 M unprotonated Alamine 336 and presented in Fig. 1.



1.0 M Cyanex 923			1.0 M Alamine 336		
C_{aq} (g/L)	C_{org} (g/L)	D	C_{aq} (g/L)	C_{org} (g/L)	D
1.8	7.5	4.2	1.4	5.9	4.4
4.2	13.6	3.2	4.1	11.4	2.8
6.1	18.1	2.9	6.1	18.3	2.9
7.9	21.2	2.7	11.8	49.4	4.2
12.0	26.0	2.2	34.1	81.3	2.4
14.5	30.2	2.1	44.3	84.4	1.9
27.2	38.1	1.4	52.1	86.5	1.6
44.1	42.4	1.0			

Fig. 1. Comparison of equilibrium curves for the extraction of 61 g/L formic acid solution with 1.0 M Cyanex 923 and 1.0 M Alamine 336 at 25 °C. D – distribution ratio.

From results it is clear that the extraction with Cyanex 923 did not seem very promising in case if extraction of a higher concentration of formic acid i.e. 61 g/L was performed. While unprotonated Alamine 336 provided much better extraction than Cyanex 923. Except few preliminary stripping studies with loaded Cyanex 923, rest of the stripping studies were carried out with 0.6 M and 1.0 M loaded unprotonated Alamine 336 as shown in Fig. 2.

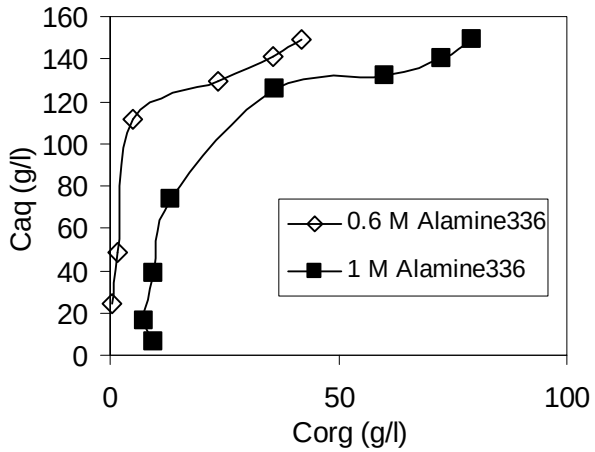


Fig. 2 Comparison of equilibrium isotherms for the stripping of formic acid from loaded Alamine 336 (0.6 M loading=49.6 g/L, 1 M loading=86.6 g/L) with 3 M NaOH at T=25 °C.

From the equilibrium data presented, it can be concluded that Alamine 336 allows concentration of formic acid in the form of formate by liquid-liquid extraction. However, the concentration ratio obtained was about 2 times. Moreover, as mentioned, a reasonable amount of sulfuric acid was required to adjust the pH before extraction. Therefore, some of these uneconomical aspects of the previous studies prompted us to try the removal of formaldehyde with Fenton process.

Oxidation of formaldehyde in acidic medium

The oxidation of formaldehyde in acidic medium using Fenton reagent was also carried out. Kajitvichyanukul et al. [2006 and 2008] also studied formaldehyde degradation using Fenton and photo-Fenton processes. They obtained almost complete removal of total organic carbon (TOC) content in 4 h. However, for industrial purposes 4 h reaction time seems long enough so the aim of the present study was to try other conditions to degrade formaldehyde in less time. Therefore, in all the experiments carried out, the reaction time was limited to 2 h only.

Usually phenolic resin plants discharge different concentrated effluents and for instance a Portuguese phenolic resin company discharges effluents namely 'Low' and 'High' containing 0.4-3 g/L and 10-40 g/L formaldehyde respectively. So some preliminary experiments were carried out with varying initial concentration of formaldehyde and it was found that initial concentration of formaldehyde did not effect much on the % removal of TOC if all other conditions were kept same. On the basis of these results, a low initial concentration of formaldehyde i.e. 2 g/L was selected for all subsequent studies.

The effect of pH on degradation of formaldehyde was studied at initial pH 1.6, 2.5 and 3.5 at different mole ratio of hydrogen peroxide to formaldehyde. The results are depicted in Fig. 3.

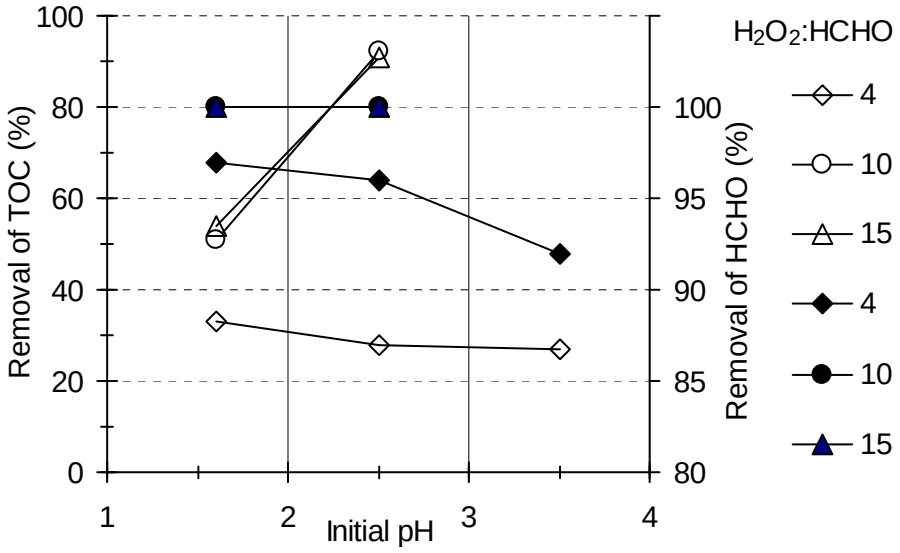

Fig. 3 Effect of initial pH on degradation of HCHO with Fenton process for mole ratio H_2O_2:HCHO 4, 10 and 15; [HCHO]=2 g/L (0.067 M), [Fe^{2+}]=0.013 M, T=25 °C, (open symbols: TOC removal, solid symbols: HCHO removal).

From Fig. 3, initial pH 2.5 allowed highest removal of TOC in case of ratio H_2O_2:HCHO 10 and 15. So in all further experiments initial pH 2.5 was adjusted. It is worth mentioning that pH 3.5 decreased to 2.5 after 2 h, whereas pH 2.5 decreased less than 0.1. Concerning the removal of formaldehyde, almost 90-100% was achieved in all cases. This data indicates that formation of intermediates during the course of oxidation are more resistent to degradation than the parent compound. Moreover, the usual presence of methanol in the solution of formaldehyde also inhibits the complete mineralization. These results are consistent with that observed by Kajitvichyanukul et al. [2006, 2008]. In all the experiments mole ratio HCHO:Fe^{2+} 5 was used and this data was taken from literature [Kajitvichyanukul et al., 2008].

Further, the influence of amount of hydrogen peroxide on mineralization of formaldehyde was also studied and the results of % of TOC removal in variation with H_2O_2:HCHO ratio after 1 h and 2 h are shown in Fig. 4. As observed, with ratio H_2O_2:HCHO 6, around 91% of TOC removal was achieved but only after 2 h, whereas 33 % TOC was removed after 1 h. It was found that a high amount of H_2O_2 (ratio H_2O_2:HCHO 10 and 15) was necessary to mineralize around 90% HCHO only in 1 h.

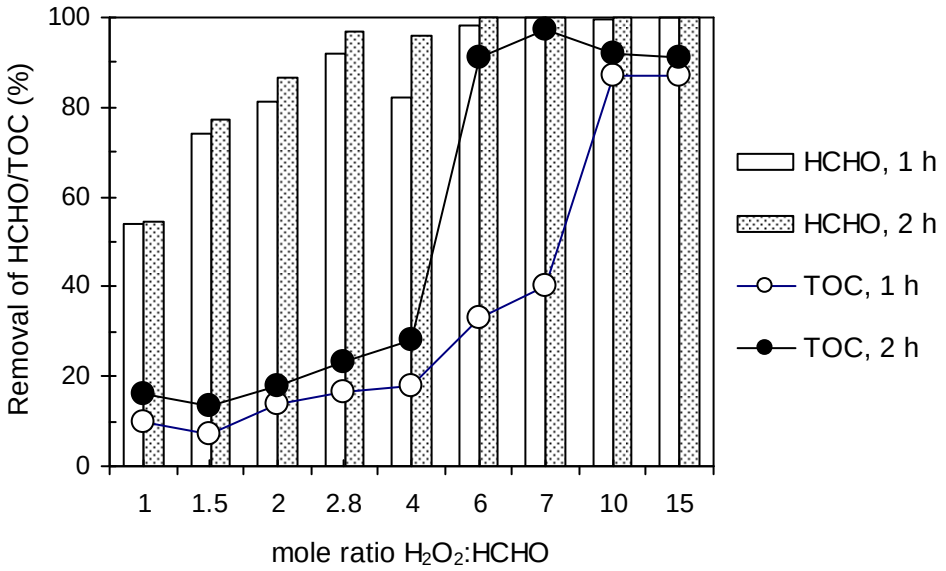

Fig. 4. Effect of amount of H_2O_2 on degradation of HCHO with Fenton process; [HCHO]= 2 g/L (0.067 M), [Fe^{2+}]= 0.013 M, T= 25 °C, initial pH 2.5.

Some experiments were then carried out under pressure and a higher temperature to try to avoid the use of such a large excess of hydrogen peroxide. The results are presented in Fig. 5. It is evident that under relative pressure of 0.5 bar, % TOC removal was higher than that obtained under atmospheric pressure, which indicates that pressure can be an important parameter in Fenton process. Besides, under pressure, augment in temperature was allowed without significant problems in decomposition of hydrogen peroxide.

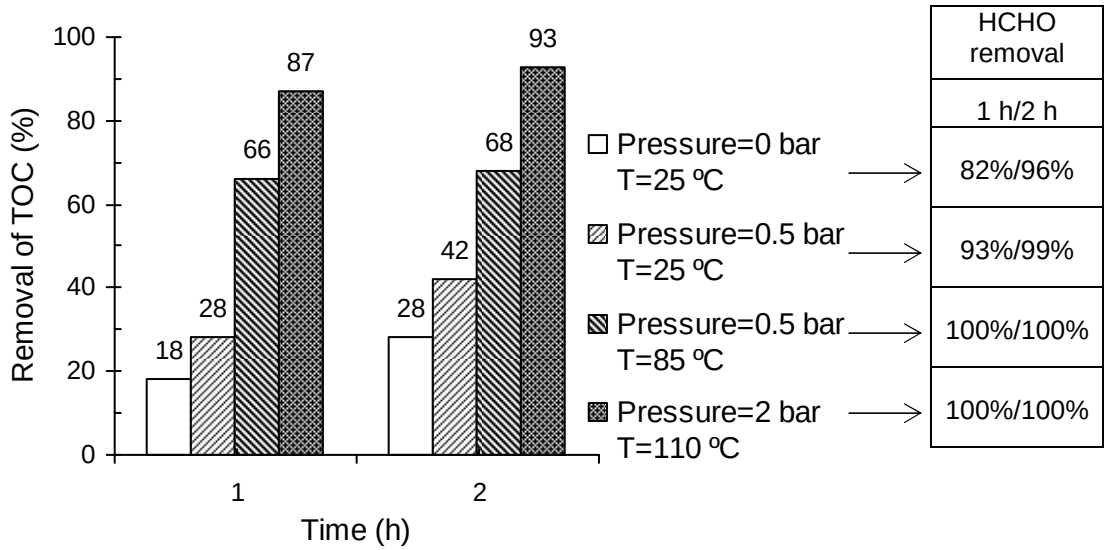

Fig. 5 Effect of pressure and temperature on degradation of HCHO with Fenton process; [HCHO]= 2 g/L (0.067 M), [Fe^{2+}]= 0.013 M, mole ratio H_2O_2:HCHO=4, initial pH 2.5.

As shown in Fig. 5, the combination of high temperature and pressure strongly enhance the kinetics of the process. The removal of TOC increased to about 70 % (relative pressure 0.5

bar and T= 85 °C) and 90 % (relative pressure 2.0 bar and T= 110 °C) after 1 h. Since the results are very promising, the influence of these parameters should be explored and optimized. Therefore, some more studies with pressure and high temperature are still in progress.

4 Conclusions

The oxidation of formaldehyde with hydrogen peroxide in alkaline medium allowed stoichiometric conversion of formaldehyde into formate ion, which could be recovered by liquid-liquid extraction. Cyanex 923 and unprotonated Alamine 336 were used as extractants and with latter better results were achieved. It is possible to concentrate about 120 g/L of formate using 3 M NaOH as stripping phase. In continuation of oxidation of formaldehyde, Fenton process was also investigated by varying some parameters at atmospheric pressure and 25 ºC like pH and amount of hydrogen peroxide. The removal of formaldehyde was very high in most cases. It was found that ratio H_2O_2:HCHO 7 provided 97% removal of TOC after 2 h and larger amounts of H_2O_2 were necessary to mineralize around 90% HCHO in 1 h. The combination of pressure and high temperature strongly increased the kinetics of the process.

Topic: Advancing the chemical and biological engineering fundamentals.

Abstract

Adsorption isotherms for the removal of linoleic acid from ethanol + water solutions using a strong anion exchange resin (Amberlyst A26 OH) were experimentally determined. The equilibrium data were correlated using the Langmuir model by adjusting the parameters q_m, maximum content that can be adsorbed on solid phase (g acid/g dry resin), and K_d, equilibrium constant (g acid/g solvent). In this way the behavior and the capacity of the resin to remove the fatty acid from the liquid phase were evaluated at different experimental conditions: the water content in ethanol was varied within the range (0 to 15) mass % and the temperature was constant 25^{o}C. It was observed that the water content in ethanol does not significantly influence the equilibrium behavior. It was also observed that the strong anion exchange resin (Amberlyst A26 OH) has a good performance in the removal of the fatty acid from the ethanolic phase.

1 Introduction

The most important step of the edible oil refining process is the removal of free fatty acids. The traditional refining methods, physical and caustic refinings, are not appropriate for crude oils with high free fatty acids content, like cotton oil as other ones. They are sensible to the severe conditions that these oils are submitted when employed the traditional refining. These oils can present large losses of neutral oil and in their nutritional value.

The interest in cotton oil is increasing because it is rich in linoleic acid, an essential fatty acid. For these reasons several investigations are performed in order to develop alternative refining methods.

The oil deacidification by liquid-liquid extraction with an appropriate solvent is one of those alternative methods. This process uses solvent for the extraction like methanol, ethanol (Batista et al., 1999), and employs mild operational conditions concerning temperature and pressure. This technology has the possibility of restricting the loss of neutral oil and nutraceutical compounds by an adequate selection of the water content in the ethanolic solvent. This technology lso allow an easy stripping of the residual solvent from the refined oil as a consequence of the very high volatility difference between ethanol and neutral oil (Rodrigues et al., 2004; Gonçalves et al., 2003).

The liquid-liquid extration generates two streams: a stream of desacidified oil (refinated), and a stream rich in solvent and free fatty acids (extract).

But the recovery of the solvent and the essential fatty acid from the extract phase was still not investigated. So the possibility of using anion exchange resins in order to adsorb fatty acids from the extract phase, allowing the recovery of the solvent and the essential fatty acid,

* Corresponding author. Tel + 551935214037. E-mail:tomze@fea.unicamp.br

was investigated in the present work. In this case the use of ion exchange resins could be considered as a complement of the whole liquid-liquid extraction process.

Actually a prior work has already investigated the treatment of the extract stream of the liquid-liquid extraction, using ion exchange resin, but in the case of oleic acid removal (Cren and Meirelles, 2005).

Nowadays, the use of ion exchange resins is very well established as a unit operation. However, investigations using ion exchange resins in fatty systems are still rare (Latip et al., 2001, Ibanez Gonzalez, et al., 2001). In this way, the study of adsorption isotherms and ion exchange mechanism in these conditions is important in order to develop new purification techniques for organic solutions.

2 Material and Methods

Material. The chemicals used in the work were commercial grade linoleic acid, Anhydrous and azeotropic ethanol and sodium hydroxide (Merck). The ethanolic solutions were prepared in mass, by adding demineralized water to anhydrous ethanol. The corresponding water concentrations were: (0,5 $\pm$ 0,01) mass % (anhydrous ethanol), (3,23 $\pm$ 0,06) mass %, (6,79 $\pm$ 0,03) mass % (azeotropic ethanol), (8,22 $\pm$ 0,04) mass % and (15,27 $\pm$ 0,27) mass %. The strong anionic resin used in the experiments was Amberlyst A26 OH (Rohm and Haas).

Methods. Equilibrium experiments were conducted in equilibrium cells, connected to a thermostatic bath, with a proportion of 1:3 of resin and solutions with different linoleic acid initial concentrations, (9,0 to 6,0) mass %. Before performing each equilibrium experiment, the resin was preconditioned, according to the procedure described by Cren and Meirelles, 2005.

The system resin + ethanolic solutions were stirred, until equilibrium was achieved (5 h). At the end of this period, the solutions were removed from each cell with the help of a syringe. The acid concentration in the solutions was determined using titration.

As usual in experiments for determining adsorption isotherms, the equilibrium concentration in the solid phase was calculated by mass balance. The mass balance was performed on a solute (linoleic acid) free basis, taking into account the initial and final oleic acid concentrations and the solvent carried by the resin into the cell. The equilibrium concentrations were also expressed on a solute free basis, as q* (g of linoleic acid/g of dry resin) versus C* (g of linoleic acid/g of solvent).

In this way the influences of water content in ethanolic solutions could be investigated.

3 results and discussion

The experimental equilibrium data obtained for each system investigated, corresponding to the counterion (linoleic acid) concentration in the solution (C*), and the concentration of counterion (linoleic acid) adsorbed in the resin (q*), are shown in Figure 1 and Figure 2.

As can be observed in these Figures, the resin can adsorb high amounts of linoleic acid. In fact, the equilibrium concentrations in the liquid phase are in most cases very low, indicating that most part of the linoleic acid dissolved in the initial solutions was transferred to the solid phase. Figure 1 shows the whole set of experimental data and Figure 2 the data obtained at low linoleic acid concentrations.

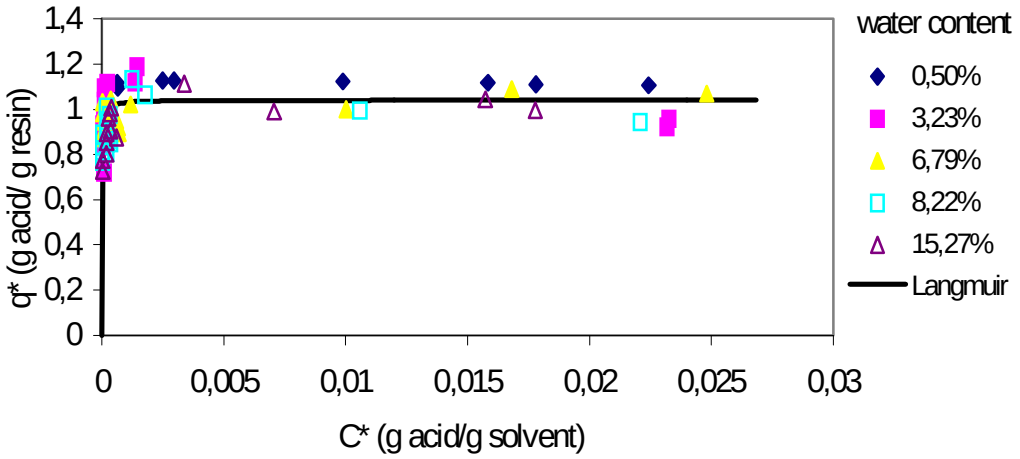

Figure 1 - Equilibrium isotherms for all experiments.

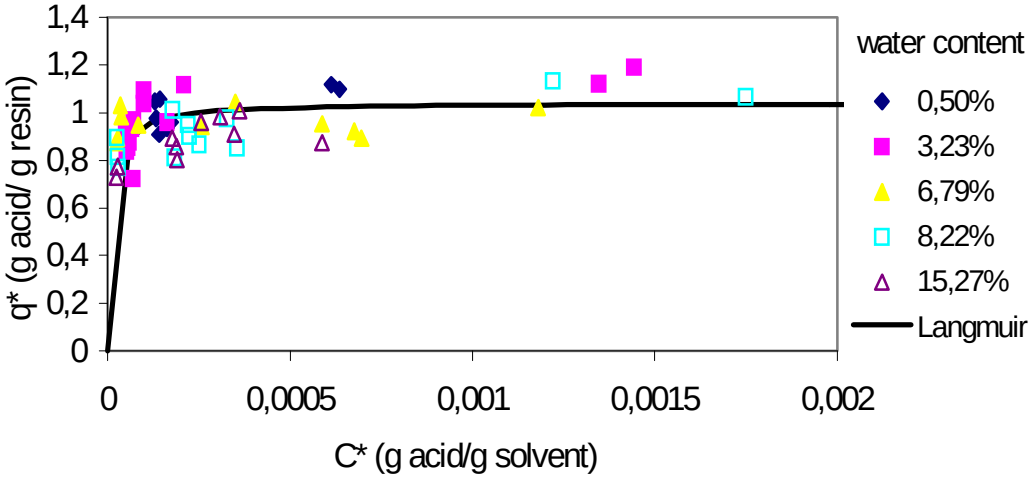

Figure 2 - Equilibrium isotherms at low linoleic acid concentrations.

The experimental data were correlated by the Langmuir equilibrium model, given in Eq. (1) below:

$$q^* = \frac{q_m \cdot C^*}{K_d + C^*} \qquad (1)$$

Where C* (g linoleic acid/g solvent) is the equilibrium concentration of the counterion in the liquid phase, q* (g linoleic acid/g dry resin) is the equilibrium concentration of the counterion adsorbed in the resin, q_m indicates the maximal adsorption capacity of the resin, K_d represents the equilibrium constant. K_d is usually interpreted as the ratio of the desorption (k_2) and adsorption (k_1) rate constants, the constants of the reversible equilibrium reaction on which the Langmuir model is based.

Most works in the literature use the Langmuir and Freundlich model for description of the equilibrium behavior using ion exchange resins (Cao et al., 2002; Antonio de Lucas et al., 1997; Anasthas and Gaikar, 1999).

The parameters of the Langmuir model varied within the range 1,00 ± 0,04 to 1,12 ± 0,02 (g acid/g resin) for q_m parameter and 1,0 ± 0,2 x 10^{-5} to 1,5 ± 0,4 x 10^{-5} for K_d parameter, considering the different water contents in the solvents.

The Average Absolute Deviations (AAD) between the experimental (q^*_{exp}) and calculated (q^*_{calc}) data were evaluated according to Eq. (2).

$$AAD = \frac{1}{m} \cdot \sum_{i=1}^{m} \left| \frac{q^*_{exp,\,i} - q^*_{calc,\,i}}{q^*_{exp,\,i}} \right| x\,100 \qquad (2)$$

Where m is the total number of experimental data. The AAD varied within the range values (0,42 to 1,26) %.

The fitting results indicate that the Langmuir model describe very well the experimental data. The K_d-values are much lower than 1, reflecting the fact that the equilibrium isotherms are favorable to the removal of the linoleic acid by the ion exchange resin and that their curvatures are convex-upward (Brunauer et al., 1940).

Taking into account the q_m and K_d-values and their standard deviations, it can be concluded that the water content in the solvent does not have a significant influence on the equilibrium behavior, at least in the range of values selected for the present work. For this reason a unique set of parameters can be adjusted to the whole set of experimental data. The following results were obtained: q_m (g linoleic acid/g dry resin) = (1,04 ± 0.01), K_d (g linoleic acid/g solvent) = (1,00 ± 0,16) x 10^{-5}, AAD = 5,74 %.

The small value obtained for the equilibrium constant, K_d, indicates that the adsorption rate constant (k_1) is much higher than the desorption rate constant (k_2), expressing the preference of the solute for the solid phase. Such result is also reflected in the high slope of the curve in the first part of the isotherm (Figures 1 and 2).

The q_m values indicate the maximal resin capacity. Taking into account the resin initial moisture, its maximal capacity can be converted to a wet basis, as it is usually reported in the literature. In this case the q_m (g acid/g dry resin) value (1,04) corresponds to 0,274 (g acid/g wet resin). Considering the bulk apparent density of the resin, this value can be further expressed as 0,65 eq/l. This result is a little lower than the capacity reported by the manufacturer (> 0.8 eq/l).

Finally it can be concluded that the water content in the solvent did not significantly influence the equilibrium isotherms. The experimental data were well correlated by the Langmuir model with low deviations between experimental and calculated data. The anionic resin presented a very good performance in the removal of linoleic acid from ethanolic solutions.

Topic: Advancing the chemical and biological engineering fundamentals.

Abstract

The traditional refining methods, physical or caustic refining, are not appropriate for some crude oils. In the case of such oils, both processes cause high losses of neutral oil and nutraceutical compounds, the physical refining is energy intensive and the chemical refining generates high amounts of soapstock. The liquid-liquid extraction is an alternative method for deacidification of crude oils, and has the advantage of using mild operational conditions concerning temperature and pressure and the possibility of restricting the loss of neutral oil and nutraceutical compounds. The liquid-liquid extraction generates two streams: the deacidified oil (raffinate), and a stream rich in solvent and free fatty acids (extract), but this process has the disadvantage of requiring the treatment of the out put streams, specially the extract stream. The solvent used in the process could be recovered and reutilized again in the process. Ion exchange resin can be employed as a complement of the whole liquid-liquid extraction process, in order to adsorb fatty acids from the extract phase, allowing the recovery of the solvent for a new liquid-liquid deacidification step. The applicability of ion exchange resins in industrial processes has steadily grown up, and generally the adsorption process uses a fluid that flow continuously through the column bed. In this way, the adsorption process investigation in a bed column allows a better understanding of the ion exchange behavior in organic media. Breakthrough curves for the uptake of oleic acid from isopropanol solutions, on anion exchange resin (Amberlyst 26A OH), at different temperatures and oleic acid concentration were studied. The breakthrough data were obtained by a study using an experimental factorial design (2^2) with surface response analysis.

1 Introduction

The deacidification of crude oils is the most important step of refining process, and is essential to convert crude oil in to an edible one. An alternative method to the conventional methods of deacidification (physical and chemical) is the liquid-liquid extraction that uses solvents for the extractions. This process has been investigated for a long time and has a good acceptance because employs mild operation conditions, minimizing the losses and damages to the refined oil (Rodrigues et al., 2004; Gonçalves et al., 2003). Some vegetable oils were investigated using the liquid-liquid extraction, like soy oil, rice oil, and the solvents generally used in this process are the short chain alcohol, like methanol, ethanol, etc (Batista et al., 1999).

However, few studies have been made for the treatment of exit streams of this process. Actually the treatment of the extract streams of the liquid-liquid extraction has been studied, using ion exchange resin (Cren and Meirelles, 2005). This streams needs treatment once it is the effluent of the process.

* Corresponding author. Tel + 551935214037. E-mail:tomze@fea.unicamp.br

This last study may help the liquid-liquid process to become viable, since the liquid-liquid extraction step was already extensively investigated. The present work investigated the possibility to use anion exchange resins in order to remove fatty acids from the extract phase and to recover the solvent

Some resin applications in process with fatty systems were found in the literature, but such studies are still scarce. For example, it can be mentioned the separation of carotene from crude palm oil using resins (Latip et al., 2001), the separation of mixture of fatty acids, of fatty esters, and of triglycerides (Adolf and Emken, 1981), and adsorption of fatty acids from metanol/ water solutions. (Ibanez Gonzalez, et al., 2001).

The advantage of using ion exchange resins to complement the liquid-liquid extraction is related to its low energy consumption, to the possibility of regeneration and rense of the resin and to the recovery of the fatty acids and other nutraceutical compounds that can be adsorbed by the resin.

2 Material and Methods

Material. Commercial grade oleic acid, isopropanol (Ecibra) and sodium hydroxide (Merck), strong anionic resins Amberlyst A26 OH (Rohm and Haas).

Methods. The experiments were conducted in a glass column with dimensions 66,5 cm (high) x 4,5 cm (diameter), aproximately 100 ml of resin previously conditioned in water and afterwards in the solvent (isopropanol), were used as adsorption media.

The resin was put in contact (continuous system) with isopropanol solutions containing oleic acid. The different oleic acid solutions concentrations were prepared in mass. The flow rate was constant at 4 bed-volume or 7 ml/min. Samples were collected in the column exit at different times. They were analyzed by titration to determine the oleic acid content. The results were analyzed by statistical method of surface response to optimize the operation parameters (temperature and initial concentration of oleic acid in solution) in the process of oleic acid removal by the resin. Figure 1 shows the squematic layout of the experiments.

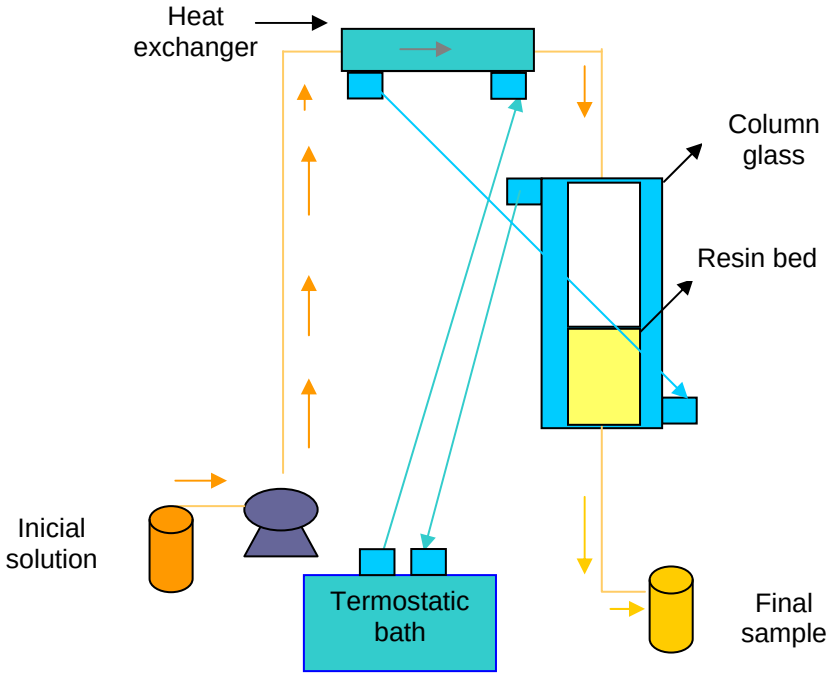

Figure 1 – Squematic breakthrough experiments.

3 Results and Conclusion

In the column study, the breakthrough curves were expressed by the adimentional concentration (C/Co) versus time (minutes). Figure 2 shows some experimental breakthrough curves.

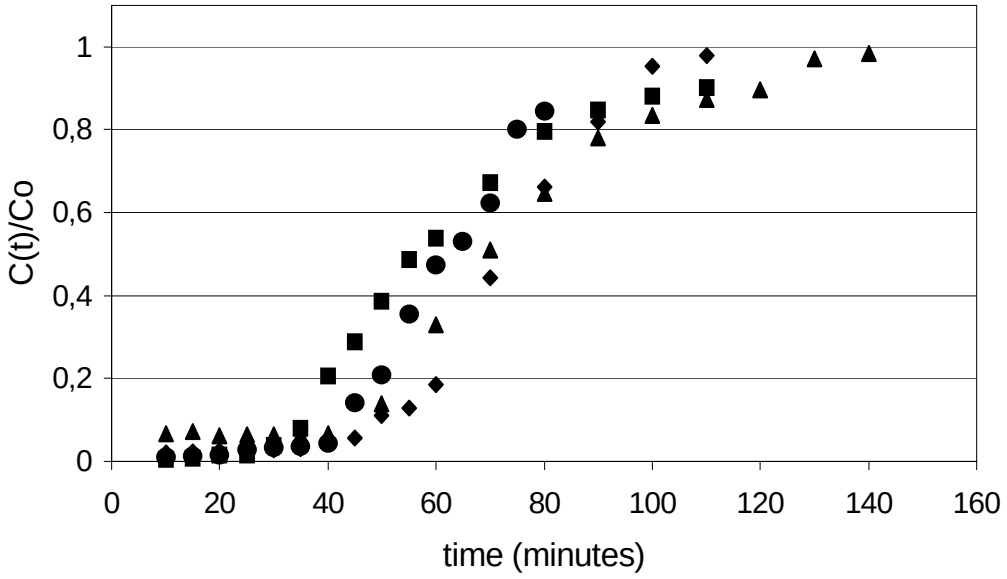

Figure 2 – Breakthrough curves (♦) 50 ^{o}C and Co = 6,5 %; (●) 46,5 ^{o}C and Co = 9,0 %; (▲) 37,5 ^{o}C and Co = 6,5 %; (■) 28,5 ^{o}C and Co = 9,0 %.

In Figure 2 above it can be noted that for a higher initial concentration the breakthrough point is reached more quickly. This fact occurs because at high concentrations the resin sites are quickly occupied, and at low concentrations the breakthrough curve become more disperse because the occupation of the sites occurs more slowly.

At the same concentration the higher is the temperature, slower the breakthrough point is reached and faster the saturation time is reached. This occurs because at high temperature the viscosity is lower, so the ions have better accessibility to the sites. In this way the sites are occupied efficiently and faster.

The breakthrough data for the isopropanol solutions were obtained using an experimental factorial design (2^2) with surface response analysis. At these experiments 2 factors were studied, the temperature (25 to 50 ^{o}C) and oleic acid concentration in isopropanol solution (3 to 10 mass %). The objective was to analyse the effects of the parameters in the efficiency of oleic acid removal by the resin.

The efficiencies are defined in Equations 1 and 2 (see Figure 3) in terms of different areas represented in the breakthrough curve. They were obtained by integration of the areas using the rectangular method (Shidhar et al., 1994).

$$Er = \frac{m_s \cdot Co \cdot \left(t_b - \int_0^{t_b} \frac{C(t)}{Co} dt \right)}{m_s \cdot Co \cdot t_b} = \frac{A1}{A1 + A2} \quad (1)$$

$$EF = \frac{m_s \cdot Co \cdot \left(t_b - \int_0^{t_b} \frac{C(t)}{Co} dt \right)}{m_s \cdot Co \cdot \left(t_f - \int_0^{t_f} \frac{C(t)}{Co} dt \right)} = \frac{A_1}{A_1 + A_3} \quad (2)$$

Where Er = efficiency of solute recovery, EF = efficiency of resin utilization, A1 = capacity of the resin efficiently used (g solute) (area above the curve until the breakthrough point (0,1.Co)), A2 = total amount of solute contained in the effluent (g solute) (area beneath the curve until the breakthrough point), A3 = capacity of the resin not efficiently used (g solute) (area above the curve after the breakthrough point and before the saturation (≥0,9.Co)).

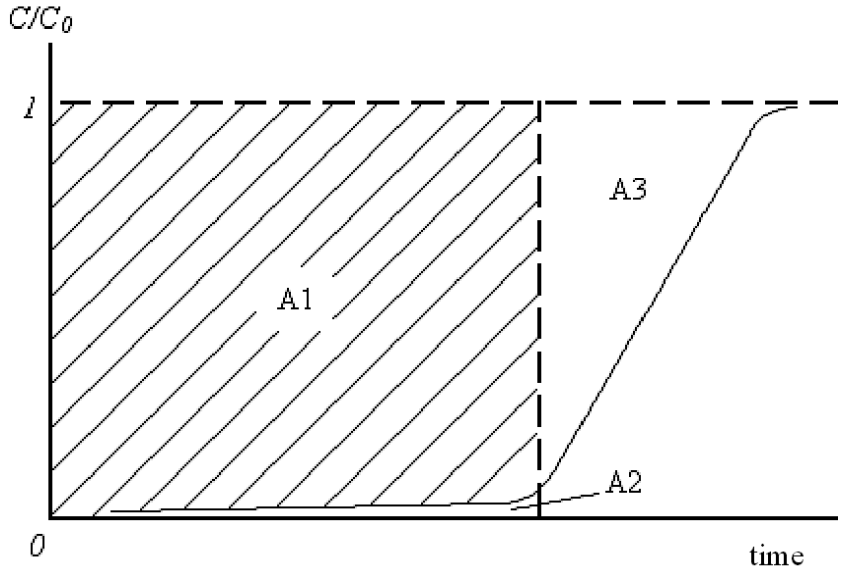

Figure 3. Breakthrough curve and the different areas associated to the process.

The efficiency of solute recovery (Er) was always larger than 78%, and was not influenced by temperature but positively influenced by the oleic acid concentration (higher the oleic acid concentration higher is the efficiency of recovery). The efficiency of resin utilization (EF) varied in the range of 21% to 66%, and was influenced positively by the oleic acid concentration as by temperature. The mainly effect is attributed to changes in oleic acid concentrations. The experimental data for breakthrough curves were analyzed by the response surface methodology, in order to maximize the response function, that is the efficiency of resin utilization, considering the parameters temperature and initial oleic acid concentration. Figure 4 shows the surface response obtained from the model by the statistical study using the data of the experimental design.

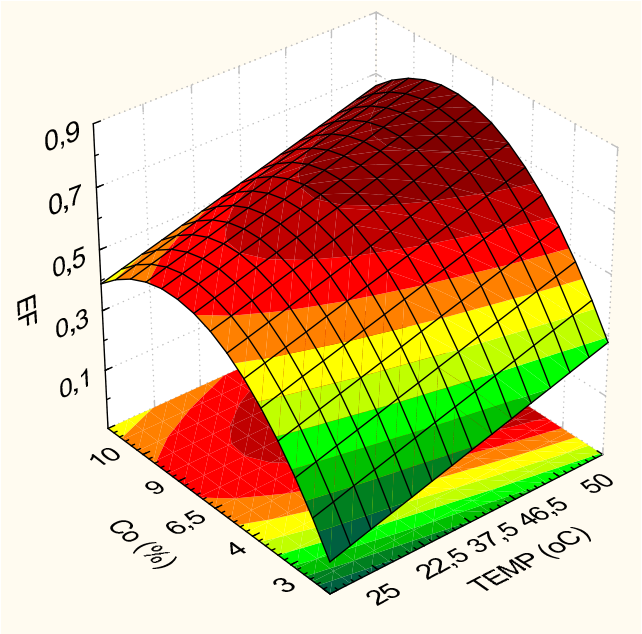

Figure 4 - Surface response, effects of temperature and concentration on the efficiency of utilization.

Figure 4 shows that the maximum efficiency occurs at high temperatures and high concentrations, and the maximum value was around 66%. So higher the concentration of oleic acid in solution and the temperatue, higher is the response function (EF), more oleic acid is removed efficiently by the column. In this way, the parameters have a positive influency in the efficiency of utilization.

From these experimental data, a good efficiency of recovery was obtained for all experiments, (78 to 98 %). This fact indicates that a high capacity of oleic acid removal was achieved.

Generally it could be concluded that the ion exchange resin shows good capacity of removing oleic acid from ethanolic solutions.

Chromium removal by constructed wetlands: evaluating the effects of chromium rich industrial effluents

Dina M.R. Mateus*, Ângela Leonardo, Filipe Pequeno, Henrique J.O. Pinho

Keywords: chromium removal, wastewater treatment, constructed wetlands
Topic: Sustainable process-product development through green chemistry

Abstract

Two constructed subsurface flow pilot wetlands, normally used for nutrients removal from a secondary treated urban wastewater, were monitored for trivalent chromium removal efficiency and for its impact over the nutrients removal primary function of this pilot plant. Cr(III) solutions were pulse injected in the pilot wetlands inflow, and wetlands outflow collected and analysed for this metal by a colorimetric technique. A total chromium removal was obtained by the wetland with macrophyte plants, and a minor removal of nearly 65% by the control wetland without plants. Under the conditions applied, no negative effects were detected over the nutrient removal capacity of both pilot wetlands resulting from chromium presence.

1 Introduction

Contamination of natural waters by heavy metals is of great concern due to its toxicological effects. The presence of heavy metals in the environment results normally from anthropogenic activities. To reduce the emissions, the industrial metal rich effluents should be subject to adequate treatments before their discharge, which can be extremely expensive. Usually these wastewaters are joined to domestic waters, after some initial physicochemical treatment, resulting in the so-called urban wastewaters, which are further treated at municipal facilities. This practice may cause problems since municipal treatment plants are as a rule designed for domestic wastewaters, and consequently the heavy metals removal is usually scarce.

Constructed wetlands (CW) may complement or replace the typical secondary treatment operations, but its efficiency concerning metals removal from wastewater and the effects of the metal pollutants over these complex environments should be addressed.

Chromium has been selected for the present study, as an example of this problem, with regard to its industrial use and potential pollution impact. This pollutant typically occurs in the trivalent or hexavalent form. The late is the most toxic, and the most common specie in industry, but is relatively unstable and was normally converted to the trivalent form at industrial localized wastewaters plants. For that, the trivalent chromium is the dominant form in the inflow of municipal treatment plants.

Wastewaters from tannery, metal plating and many other industries contain high chromium concentrations, namely hexavalent chromium (Nriagu and Niober, 1988). Common treatment of industrial chromium rich effluents conducted at industrial plants consists mainly in physicochemical processes that transform Cr(VI) into Cr(III) with subsequent precipitation

* Corresponding author. Tel + 351-249323160. E-mail:dinamateus@ipt.pt

(Abass et al, 2005; Chang, 2001; Eary and Ray, 1988). However, these processes are not totally effective, since they often still leave high chromium levels in the water discharged.

The use of CW for urban wastewater treatment is a rapidly growing practice, due to its economical and environmental advantages (Kadlec and Knight, 1996). CW specially dedicated to industrial wastewaters remediation have also been studied and implemented, with examples of application to heavy metals pollutants cited in the literature (Knight et al., 1999; Mant et al., 2006; Mitsch and Wise, 1998; Scholes et al., 1998; Vymazal, 2005). The effects of heavy metals in CW, used as secondary or tertiary treatment at municipal wastewater treatment plants dedicated mainly to common urban waters, are less reported. It should be considered that both Cr(VI) and Cr(III) have been identified as plant toxics, in particular to *Phragmites australis*, species commonly used in CW (Mant et al., 2006; Shanker et al., 2005).

The aim of this work was to evaluate the effects of sporadic chromium discharges on the performance of CW normally operated for nutrients removal.

2 Materials and methods

The CW pilot plant consists of two tanks with a working volume of 240 L, filled with lightweight aggregate (expanded clay). Tank A was planted with the emergent macrophyte *Phragmites australis*. Tank B, without plants, serves for control purposes.

To simulate sporadic discharges of industrial chromium polluted effluents on the public frameworks using CW, small volumes of Cr(III) solutions (1 L 0,005 M $CrCl_3 \cdot 6H_2O$) were injected in the pilot CW plant feed line. The CW effluents were collect and analysed for chromium concentration.

To check the chromium removal capacity of the filter media by itself, 5g-samples of the expanded clay, first washed and dried, were shaken for 24 h with 100 mL 0,010 M Cr(III) solutions, and the liquid phase analysed for chromium concentration after solids separation by filtration.

The chromium concentration was determined by the colorimetric method (Greenberg et al, 1992). Total phosphorus was quantified by the ascorbic acid method, after the samples digestion with persulfate, and total nitrogen was quantified by the 2,6-dimethylphenol spectrometric method, also after persulfate digestion of the samples (Greenberg et al, 1992). COD was determined by the titrimetric method (Greenberg et al, 1992).

3 Results and discussion

The pilot plant has been operated continuously for more than six years, performing the treatment of a typical secondary effluent. CW A average removal efficiencies were about 50% for total phosphorus, 75% for total nitrogen and 70% for COD. CW B, unplanted, showed an average removal efficiency of 30%, 50% and 55%, respectively for total phosphorus, total nitrogen and COD.

After chromium injection, the tanks outflows have been monitored to pH, temperature and volumetric flow rate. The volumes collected were sampled and analysed for chromium contents. Mass balances calculations were performed to evaluate chromium removal. Figure 1 shows the chromium concentration at CW outflow over time.

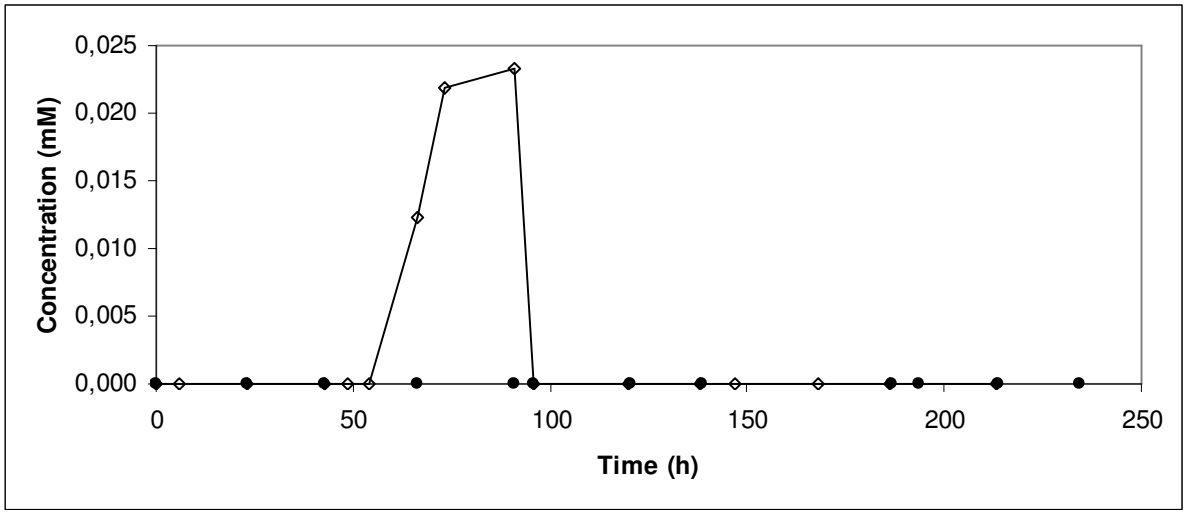

Figure 1 – Chromium concentration at pilot constructed wetlands outflow over time, after a pulse injection of a 5 mM Cr(III) solution (• tank A, planted; ◊ tank B, without plants).

Chromium removal by CW A, with plants, was verified to be 100%. The CW B, without plants, shows a lower removal capacity, near 65%. The lab tests demonstrate an only residual chromium removal by the filter media itself. From these results, we can infer a contribution of plants for the chromium removal near 35%.

To evaluate the effects of the chromium presence over the normal operation of the pilot CW, the efficiency for total phosphorus removal, total nitrogen removal and COD removal within the period of chromium experiments was compared with the efficiencies obtained at the precedent year (2006) in the same period, to contemplate the usual seasonal efficiency variations observed in these systems (Figure 2).

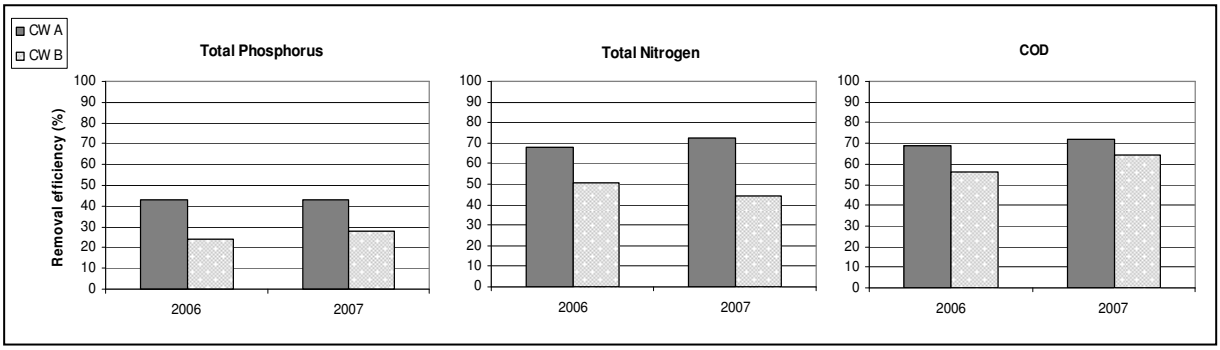

Figure 2 – Total phosphorus, total nitrogen and COD removal efficiencies of the two pilot constructed wetlands: at 2007 in the period of tests with chromium; at 2006 in the same period, before chromium experiments.

From figure 2, dismissing small variations due to the complexity of removal phenomena at CW, it can be concluded that the removal of nutrients seems not to be disturbed by the presence of the chromium in the inflow water.

4 Conclusions

The results suggest a potential chromium depuration capacity of CW, which can be attributed mainly to the action of the filter media microcosms, while plants uptake and adsorption to their roots and rhizomes contributes with 35% of the chromium removal capacity.

For the reason that the chromium removal may occur by plants uptake and, primarily, by accumulation into the filter media microcosms – sediments, humic substances and microorganisms present – concerns may be taken about the end use of filter media and the harvested plant materials.

Under the conditions experimented, the CW didn't show any efficiency loss with respect to COD and nutrients removal function. Future experiments should be conducted to evaluate the long term effects of continuous chromium feed to the CW, and to access the sustainability of chromium concentration reduction with time.

Recovery of heavy metals by hybrid membrane processes

Gryzelda Poźniak*, Ryszard Poźniak, Kazimiera A. Wilk
Department of Chemistry, Wrocław University of Technology, 50-370Wrocław, Poland

Keywords: modified poly(phenylene oxide), ultrafiltration, dialysis, zinc, copper
Topic: Sustainable process-product development through green chemistry

1. Introduction

Metallurgical industry, especially electroplating and metal finishing sectors, generate huge amounts of water containing heavy metal ions. For attempts to recover and concentrate these valuable components as well as for removal of undesired toxic ions from waste the application of membrane separation processes is very useful. This well consolidated technology has become the central focus of industry interest due to its low operational costs, conceptual simplicity, modularity, flexibility to the quality of treated water, and productivity in relation to other separation techniques [Mulder, 1991].

In order to separate ions, reverse osmosis (RO) or nanofiltration (NF) is commonly used. However, the permeating fluxes in RO and NF are not so high and both processes require the use of high transmembrane pressure. That operation turns them into more expensive membrane processes. The other pressure-driven process - ultrafiltration (UF) – needs smaller transmembrane pressure and its operational cost is not so high. It has been shown that ultrafiltration is efficient in the removal of larger molar substances (polymers, colloids) whose size ranges from 2 to 100 nm and whose molecular weight is larger than 500 Da. However, the pore size of any ultrafilter is too large to reject small molecules like inorganic ions.

The polymer enhanced ultrafiltration (PEUF) [Cãnizares et al., 2002] and micellar enhanced ultrafiltration (MEUF) [Juang et al., 2003, Poźniak et al., 2007], hybrid (non-conventional) processes, have been shown to be promising methods of removing low levels of toxic heavy metal ions from industrial effluents.

PEUF and MEUF constitute a combination of two phenomena; binding ~~of~~ metal ions to a water soluble polymer (complexation) or solubilizing by surfactant micelles, respectively, and ultrafiltration. Since the pore size of ultrafiltration membranes is not suitable for separating heavy metal ions, water soluble polymers are used to form macromolecular complexes with metal cations or anionic surfactant micelles are used to solubilize cations. Ultrafiltration membranes with pores smaller than both the polymeric agents and surfactants (above the critical micelle concentration, cmc) are employed; thus, the polymer-metal complexes or the micelle-solubilized metal can be retained while simple (non-binding or non-complex) ions pass through the membrane.

Dialysis is the oldest membrane process for removing metal ions from water in which the ions move across nonporous ion-exchange membranes, based on the Donnan equilibrium principle [Donnan, 1924]. Dialysis is a diffusion phenomenon which is governed by a difference in metal concentration on both sides of the nonporous ion-exchange membrane. The solute flux is stopped when the concentrations are equal in both compartments. The amount of metal passing through the membrane can be increased by modifying the chemical potential of the metal in one of the two compartments. If some complexion polymer is added to the feed compartment, a decrease in free metal ion concentration will lead to a decrease in the transfer rate of metal ions to the receiving compartment [Wang, 2004].

In contrast, if the complexion polymer is added to the receiving compartment, the interaction of the metal ions with polymer (polymer-metal complex formation) should be responsible for an increase in the amount of metal ions transferred. In the case of stable complex formation, it should be possible to recover the total amount of metal ions in the receiving compartment

[Marty et al., 2000, Poźniak, 2006a]. In the PED a porous membrane is used. The transport rate through the porous membrane is significantly larger than the rate through a solid membrane – this is another benefit resulting from the application of the PED process.

Poly(phenylene oxide) (PPO) is frequently used as a membrane material due to its good mechanical strength, thermo-, biological, and chemical stability, and film-forming properties. Hydrophobicity, the shortcoming of the PPO membrane, can be counterbalanced by introduction of ionic functional groups to the polymer chain. The porous ion exchange membranes form a new category of filtration media. They proved to be very useful in the filtration of charge-bearing solutes [Bryjak et al., 2004; Poźniak et al., 1995, 2002, 2006b].

The goal of this paper is to evaluate a possibility to prepare membranes from aminated and sulfonated poly(phenylene oxide) and to determine the usefulness of porous ion exchange membranes in the hybrid separation processes for removal of Zn(II) and Cu(II) ions from aqueous media.

2. Experimental

2.1. Amination of poly(phenylene oxide)

PPO (M_v=27,000, from Aldrich Chemie) was chloromethylated using a mixture of methyl chloromethyl ether (8 mole per mer PPO) with $SnCl_4$ (0.1 mole per mer PPO) in a solution of 1,2-dichloroethane (10 wt. %). The reaction was conducted for 1 h at room temperature. Membranes were formed from the chloromethylated product.

Aminolysis of chloromethylated membranes was performed in 50 vol. % solution of N,N-dimethylaminetanol in 1:1 (vol.) mixture of water and methanol. The reaction was completed within 24 h at room temperature. The sample symbol is APPO.

2.2. Sulfonation of poly(phenylene oxide)

PPO was sulfonated in a solution of chlorosulfonic acid and chloroform at room temperature for 2 h. The concentration of PPO in chloroform was 10 wt. % and the molar ratio of chlorosulfonic acid to polymer was 0.25:1. The sample was called SPPO.

2.3. Preparation of membranes

Porous asymmetric membranes were formed by means of the phase-inversion method from: native PPO, chloromethylated PPO and sulfonated PPO. The concentration of all polymers in a mixture of chloroform and nonyl alcohol (8:2 ratio by weight) was 10 wt. %. Methanol was used as a coagulation medium.

2.4. Transport properties of membranes

The dead-end UF apparatus (Amicon 8200) with membrane filtration surface area of 19.6 cm^2 was used for determination of water flux and filtration of 1 mM solution of $ZnCl_2$ and $CuCl_2$. Transport measurements were run under the transmembrane pressure of 0.05 MPa in MEUF and PEUF. Sodium dodecyl sulfate, SDS, (critical micelle concentration, cmc = 8.1 $mmol/dm^3$) in MEUF, and polyethyleneimine, PEI, (M_w=25,000) in PEUF were applied.

The dialysis cell was divided into two identical compartments (35 cm^3) separated by the SPPO membrane. One of them contained the metal salt ($CuCl_2$) and the other the poly(acrylic acid-co-maleinic acid) (M_w=50,000).

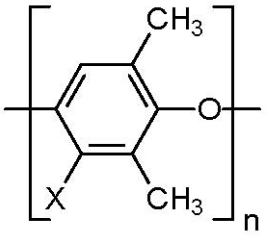
The concentration of metal cations was determined with AAS (AAnalyst 100, Perkin-Elmer). To evaluate the filtration efficiency in removing the zinc and copper cations from the feed solution, we used the rejection (R) expressed as:

$$R = [1 - (C_p/C_o)] \times 100$$

where:
C_p and C_o – are the cation concentrations in the permeate and in the initial feed, respectively.

3. Results

It is known that amination of a polymer results in the introduction of positive charges on the membrane surface while sulfonation results in the introduction of negative ones.



$$X = -SO_3^- \text{ or } -CH_2N^+(CH_3)_2C_2H_4OH$$

The properties of obtained membranes are shown in Table 1.

Table 1. Properties of porous ion exchange membranes

Membrane	Ion exchange capacity mmol/g	Porosity %	Average pore diameter nm
PPO	0.00	72	12
APPO	0.94	73	23
SPPO	1.45	83	21

For each evaluated membrane, the transport enhanced species was selected. The selection criterion was to keep the same charge on both bodies: the membrane and the species. For Zn(II) and Cu(II) cations recovery, APPO membrane with PEI was used in PEUF mode while SPPO membrane for MEUF mode with SDS as the surfactant.

It is predictable that ion removal according to the PEUF mode should be strongly related to the pH of the solution. To see that effect the process was evaluated at pH=3, 5 and 7 keeping the same molar ratio of salt to PEI, namely 1:4 – Figure 1.

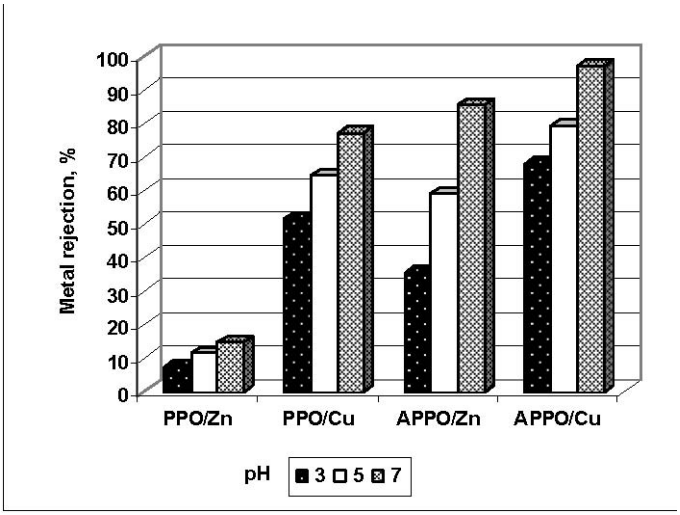


Fig. 1. Dependence of Zn(II) and Cu(II) rejection on pH and type of membrane – PEUF process

In the case of MEUF mode, the sorption of cations is mostly related to the surfactant concentration. For the purpose of this work SDS concentration was set at 8.1 and 40.5 mmol/dm^3, that is equivalent to 1 and 5 x critical micelle concentration, cmc) – Figure 2.

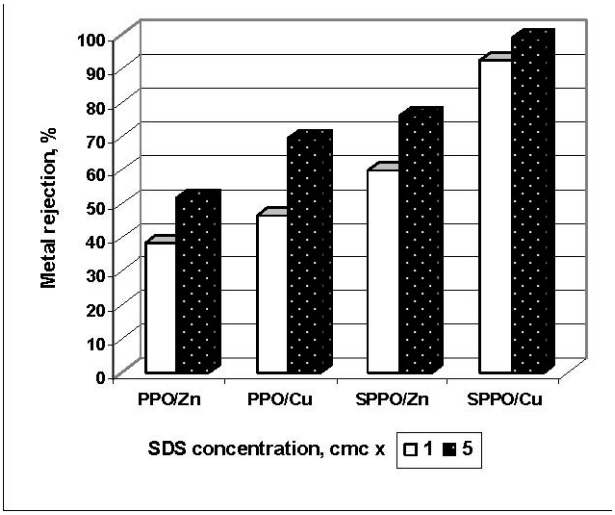

Fig. 2. Dependence of Zn(II) and Cu(II) rejection on SDS concentration and type of membrane - MEUF process

When comparing the degree of metal rejection in PEUF and MEUF processes one may note the positive effect of the presence of ionogenic groups. In both processes zinc and copper are better separated by modified PPO membranes. In PEUF and MEUF, stronger effect of Cu(II) interaction with PEI and better solubilization with SDS micelle were observed.

An ordinary dialysis of Cu(II) was also compared to the PED process. It is predictable that ion flux depends on the molar concentration ratio of the polymer to the cation and on the pH of the receiving phase [Marty et al., 2000]. In our experiments, the concentration of Cu(II) in the feed solution was kept as 10^{-3} mole/dm^3 and the concentration of the polymer in the receiving solution was equal to 10^{-2} mole/dm^3 while pH = 7. The course of metal ions concentration in the feed and receiving compartments along with the time of dialysis is presented in Figure 3.

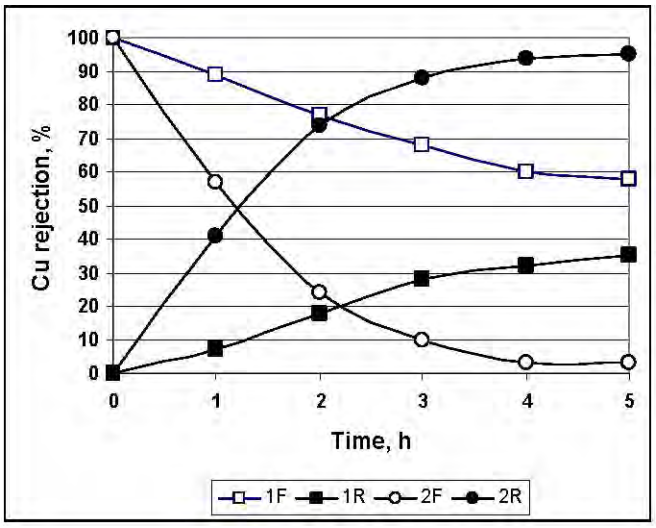

Fig. 3. Cu(II) concentration in the feed and in the receiving solution in the absence (1F, 1R) and presence (2F, 2R) of poly(AA-coMA) for SPPO membrane – PED process

For runs without the polyelectrolyte, natural dialysis of the metal ions is observed; the concentration of Cu(II) in the receiver is lower than 50% (curve 1R). The interaction of metal ions with poly(AA-co-MA) is mainly due to electrostatic forces and the formation of coordinating bonds. Hence, in the presence of polyelectrolyte, the concentration of metal ions in the receiving solution (curve 2R) increased to 100%.

4. Conclusions

1. Zn(II) and Cu(II) ions can be removed from aqueous solutions in the PEUF process with APPO membranes as well as in the MEUF process with SPPO membrane. In the first case polyethyleneimine should be used as a complexion agent while the second process should be assisted by a micelle formed by SDS.
2. Dialysis enhanced by poly(AA-co-MA) can recover nearly 100% of Cu(II).
3. The sulfonated and aminated poly(phenylene oxide) membranes worked more effectively than the neat membrane from poly(phenylene oxide) in all investigated processes (the positive effect of the presence of ionogenic groups).

Topic: Sustainable process-product development through green chemistry.

Abstract

The capacity and mechanism of mono and bi-functional reactive dye adsorption utilizing a new adsorbent obtained from the dried residual sludge (~10% w.w.) of a textile wastewater treatment system was studied. With the focus on determining the efficiency of the adsorbent in the dye removal, the adsorption isotherms were determined for the reactive dyes RR2 and RR141, at different temperatures and salt concentrations. The experiments were carried out in fixed bed adsorption columns, which were defined as the best adsorption experimental condition for both of the dyes through the parameter q_m (mg/g), obtained by the adjustment of Langmuir isotherms. Breakthrough curves for the dyes RR2 and RR141 were obtained varying the height to which the fixed bed columns were packed with adsorbent (15, 30 and 45 cm) and varying the adsorbate feed rate in the column (8, 12 and 16 mL/min). For the dye RR2 the maximum adsorption capacity was 53. 48 mg/g and for the dye RR141 it was 78.74 mg/g.

1 Introduction

There is no single process capable of adequate mineralization of colored effluents, mainly due to their complex nature (Jain *et al*., 2002). Thus, a final refining treatment is required, usually involving oxidative processes, with ozone, Fenton's reactant, or hydrogen peroxide + UV radiation, membrane separation or adsorption (Órfão *et al*., 2006).

In adsorption processes, activated carbon is widely used, and it can be employed in fixed bed columns (Órfão *et al*., 2006). Due to the high cost of some conventional adsorbents, researches have been directed to the use of alternative adsorbents, like bottom ash, sludge, red mud, etc. (Calvo *et al*., 2001; Jain *et al*., 2002). Throughout this essay, a new adsorbent developed from the dried residual sludge of a textile wastewater treatment system (Ulson de Souza *et al*., 2007) is studied. With the goal of determining the efficiency of this adsorbent in dye removal, the adsorption isotherms were determined for the reactive dyes RR2 and RR141, at different temperatures and salt concentrations. Defined as the best experimental adsorption condition for both dyes, through the parameter q_m (mg/g) obtained by the adjustment of the Langmuir isotherm, we carried out the experiments in fixed bed adsorption columns.

2 Materials and Methods

2.1 Preparation of samples

The absorbent under study is a dried residual sludge of a textile industry wastewater treatment system with approximately 10% w.w., obtained from a textile processing factory in the region of Blumenau, SC, Brazil. The adsorbent was obtained after the residual sludge passed through a thermal treatment step followed by chemical treatment, as described by Ulson de Souza *et al*., 2007. The thermal treatment step occurred at 500°C and after heating the sample was chemically activated with 1M acetic acid.

The two dyes used as the adsorbates were CI Reactive Red 2 (monoazo) and CI Reactive Red 141 (diazo). The chemical structures and properties of these dyes are described in Netpradit *et al*., 2004. The standard solutions of the dyes were prepared from stock solutions of 2000 mg/L as per the methodology given in Netpradit *et al*., 2004. The spectrophotometrical analysis was performed at the wavelength of maximum adsorption (λ_{max}), with a spectrophotometer UV-Vis (Cary 50, Varian). When necessary, the pH of solutions was adjusted with 0.1M acetic acid or 0.1M sodium hydroxide.

2.2 Adsorbent Characterization

The surface area values were calculated as per the method described by Brunauer-Emmett-Teller, BET (Brunauer *et al*., 1938) using a Quantachrome Autosorb - 1C instrument. To obtain a micrograph of the physical structure of the adsorbent, and to carry out the EDS analysis, scanning electron microscopy (SEM) (Philips, Model XL30) was used.

2.3 Equilibrium Studies

The adsorption isotherms were determined through batch experiments where 100 mL of solution containing different adsorbate concentrations (100 to 2000 mg/L – pH 4.0) were transferred volumetrically to 250 mL Erlenmeyer flasks containing 1g of adsorbent, which remained under agitation for 6h in a shaker.

The data obtained from the adsorption experiments were adjusted according to the Langmuir isotherm which is based on the hypothesis that the forces of interaction among the molecules adsorbed are negligible and that each site can be occupied by only one molecule – Equation 1 (Órfão *et al*., 2006, Kumar and Sivanesan, 2006, Fernandes, 2005).

$$q_{eq} = \left(q_m K_L C_{eq}\right) / \left(1 + K_L C_{eq}\right) \quad (1)$$

where q_m is the maximum quantity of dye adsorbed per unit adsorbent mass (mg/g), K_L, is Langmuir equilibrium constant, (l/g); C_{eq} is the adsorbate concentration in equilibrium, mg/L.
The essential characteristics of a Langmuir isotherm can be expressed in terms of a separation factor non dimensional constant, commonly called the equilibrium parameter, R_L. The value of R_L indicates the type of adsorption isotherm, as reported by Ciola, 1981.

2.4 Experiments in fixed bed column

The experiments were carried out in adsorption columns with dimensions of 1.43 cm diameter and 36 cm height, to investigate the influence of the process parameters on the removal of mono and bi-functional reactive dyes. The feed dye concentration in the adsorbate solution used in the continuous experiments was 500 mg/L, and this was acidified with acetic acid 0.1M (pH 4.0) and for the adsorbate RR141, 10% sodium chloride (NaCl) (% in mass) was added. Breakthrough curves for the dyes RR2 and RR141 were obtained varying the packed height of the fixed bed columns with 15, 30 and 45 cm of adsorbent and varying the adsorbate feed rate in the column to 8, 12 or 16 mL/min.

Also, the adsorption capacity in equilibrium (column saturation) for the different operational conditions previously described was determined. Due to the high adsorption capacity of the

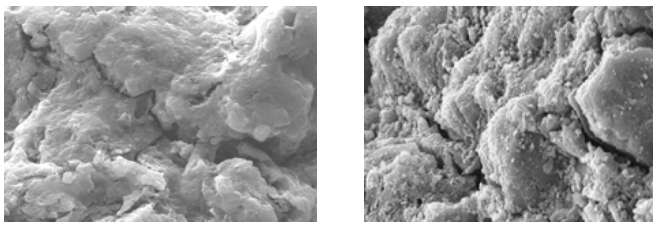
adsorbent, the breakthrough curves were obtained until the concentration of adsorbate in the outlet of the column reached 80% of the feed concentration (C/Co=0.8).

3 Results

3.1 Adsorbent Characterization

The adsorbent has a B.E.T surface area (Brunauer *et al*., 1938) of 137.61 m^2/g, total pore volume of 2.76 x 10^{-1} cm^2/g, and pore diameter of 8.032 $\mathring{A}$. The chemical composition of the adsorbent is: carbon (21.38%), oxygen (21.61%), sodium (0.72%), manganese (1.6%), aluminum (19.06%), silica (17.88%), phosphorus (10.8%), potassium (1.22%) and calcium (5.73%).

The image analysis and determination of the chemical composition of the adsorbent were carried out by SEM. Figure 1 shows images of the surfaces at a magnification of 1000X for the adsorbent under study as well as for a commercial adsorbent [activated carbon Fitrasorb 200 – Calgon, USA] (Chen and Chu, 2002).



(a) (b)

Figure 1 - Microscopic surface of adsorbents (a) adsorbent under study (thermally and chemically activated residual sludge) (b) commercial activated carbon Fitrasorb 200.

The structure of the adsorbent is comparable to that of a commercial activated carbon sample (Fitrasorb 200) (Figure 1 (b)).

3.2 Equilibrium Studies

Table 2 shows the Langmuir isotherm equilibrium parameters for different experimental conditions. It can be observed that the maximum adsorption capacity of the adsorbent, (q_m), decreased while the temperature of the adsorption experiments increased, for both dyes. With the addition of different concentrations of sodium chloride to the solution with adsorbate RR2, q_m reduced as the concentration of this salt is increased. For the experiments carried out with the addition of sodium chloride, for both dyes, good correlation coefficients were obtained (0.907 to 0.987).

When different masses of sodium sulfate were added to the solution with the adsorbate RR2, q_m increased in relation to the addition of NaCl. For the dye RR141 there was a small reduction in q_m when compared to the adsorption experiments in the presence of NaCl. In Table 2 it is possible to identify the best adsorption conditions (highest q_m value (mg/g)). For the dye RR2, the best adsorptive condition is at 25°C with a complete absence of salt in the solution, but for the dye RR141, the best adsorptive condition was at 25°C in the presence of 10% (by mass) of sodium chloride in the solution. There was a 58.81% reduction in the adsorption capacity of dye RR2 when 10% of sodium chloride was added to the solution and there was a 15.33% reduction for dye RR141 when 10% of sodium sulfate to was added to the adsorbate.

Table 2 - Langmuir isotherm equilibrium parameters for the different experimental conditions.

Dyes	Temperatures (°C)	Langmuir parameters		
		K_L(L/mg)	q_m(mg/g)	R^2
RR2	25	0.113	53.476	0.928
	40	0.275	31.746	0.872
	60	0.077	24.876	0.954
RR141	25	0.209	66.670	0.997
	40	0.199	65.789	0.976
	60	0.117	51.020	0.984
	NaCl Concentration (% mass)			
RR2	1	0.104	45.450	0.907
	5	0.366	30.120	0.930
	10	0.409	22.026	0.931
RR141	1	0.210	44.248	0.987
	5	0.091	47.619	0.967
	10	0.077	78.740	0.984
	Sodium Sulphate Concentration (% mass)			
RR2	1	0.051	47.393	0.985
	5	0.291	39.850	0.965
	10	0.191	39.526	0.991
RR141	1	0.347	52.356	0.912
	5	0.750	40.161	0.862
	10	0.004	66.667	0.960

(*)The experiments with salt were carried out at 25°C.

For the best adsorption conditions, for both dyes, R_L varied from 0.02 to 0.75 as shown in Table 3, indicating that these isotherms are favorable (Ciola, 1981).

In Table 3 the removal percentages for dyes RR2 and RR141 for the best adsorption experimental conditions and with initial dye concentrations of 100 and 500 mg/L are shown.

Table 3 - Removal percentage for dyes RR2 and RR141 for the best adsorption conditions with initial concentrations of 100 to 500 mg/L.

Adsorbate	Temp. (°C)	Co (mg/L)	Ce (mg/L)	qe (mg/g)	%Removal	R_L
RR2	25	500	57.14	44.29	88.57	0.1313
		100	0.274	9.97	99.73	0.9693
RR141 with 10% (by mass) of sodium chloride	25	500	21.37	47.86	95.72	0.3783
		100	47.86	2.798	97.20	0.8230

From the removal percentage data given in Table 3, the great effectiveness of the color removal by the adsorbent for both dyes studied can be verified.

3.3 Continuous Experiments

Breakthrough curves were obtained for dyes RR2 and RR141 under the best adsorption conditions shown in Table 2. The porosity of the packed bed has a value ε=0.42. The curves in continuous experiments were obtained for dye RR2 at the operation temperature of 25°C with different bed heights and flow rates and for dye RR141 at the temperature of 25°C with addition of 10% (w:w) of sodium chloride (NaCl) to the column feed solution, also using different feed rates and bed heights. The breakpoints for these conditions are shown in Table 4.

Table 4 – Breakpoint (t_b) and amount of dye removed by the adsorbent in equilibrium for the dyes RR2 and RR141.

Dye	Feed rates (mL/min)	Bed heights(cm)	t_b(min)	q_{eq} (mg/g)	Dye	Feed rates (mL/min)	Bed heights (cm)	t_b (min)	q_{eq} (mg/g)
RR2	8	15	170	13.70	RR141	8	15	320	38.69
		30	290	19.00			30	530	48.56
		45	430	19.55			45	820	57.70
	12	15	100	16.41		12	15	210	41.73
		30	165	27.20			30	360	49.25
		45	210	21.51			45	490	44.70
	16	15	55	13.42		16	15	160	39.98
		30	100	17.08			30	290	45.82
		45	190	18.60			45	330	42.37

For the dye RR2 the column saturation time, when operated with a fixed bed height of 15 cm and flow of 16 mL/min, was only 55 min and for a flow of 8 mL/min it was 3.1 times greater. For the dye RR141 the saturations time under the same conditions were 160 and 320 min, respectively. When the column operated with a solution of dye RR2 the operation time was shorter than with the dye RR141, for the different flows studied, as a consequence of the magnitude of the values obtained for q_m, 53.48 and 78.74 mg/g, for the dyes RR2 and RR141, respectively.

Guelli U. Souza *et al*., 2008, studied the adsorption of the dye Basic Green 4 in fixed bed columns packed with granular activated carbon for different feed rates. For a feed rate of 3.2 mL/min the breakpoint occurred in twice the time compared to a feed rate of 6.0 mL/min

Figure 2 shows the breakthrough curves for the dyes a) RR2 and b) RR141 for different bed heights and a feed rate fixed at 16 mL/min.

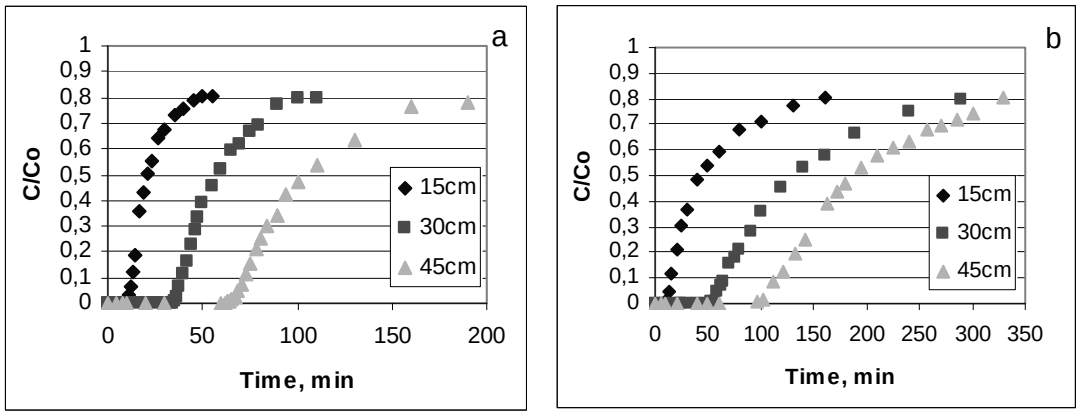


Figure 2 - Breakthrough curves for the dyes a) RR2 (T=25°C) and b) RR141 (T=25°C-10% NaCl) with different bed heights for a feed rate of 16 mL/min.

According to Figure 2, it can be observed that an increase in the critical bed height leads to a slower column saturation, due to the larger quantity of adsorbent, which increases the time of the column operation. For a bed height of 45 cm and fixed feed rate of 12 mL/min, the saturation time for the dye RR2 was 52.38% greater, when compared to a bed height of 15 cm and for the dye RR141 under the same conditions the saturation time was 57.14% greater when compared to the bed height of 15 cm. The adsorption capacity in equilibrium increased with the increase in the height of packed column from 15 to 30 cm and for the feed rate increase there were no significant variations in this parameter.

The experimental results were compared with data given in the literature showing a higher adsorption capacity of the adsorbent under study. The adsorbent here investigated represents as a very promising alternative in terms of an environmentally correct process,

focusing on a reduction in the environmental impact of dyes from the textile industries on water sources.

4 Conclusions

The great effectiveness of the absorbent was verified through the color removal for both dyes studied, where the percentage removal for the dyes RR2 and RR141 under the best adsorption conditions, with initial concentrations of 100 and 500 mg/L, were 88.57% and 99.73%, respectively, for the dye RR2 and 95.72% and 97.20% respectively for the dye RR141. The presence of salt in the system is a factor which interferes in the adsorption performance, according to the quantity and the chemical species.

The parameters determined in the continuous experiments will be used for the design of prototype columns in industrial scale. The adsorption capacity in equilibrium increased with an increase in the packed column height from 15 to 30 cm and there was no variations with the feed rate increase.

The use of this new adsorbent can be recommended for the final stage of the wastewater treatment process, where neutralization is required by the environmental legislation, considering that the best performance of the adsorbent occurs in an acid environment.

Keywords: activated carbon, steam activation, catalytic oxidation, phenol
Topic: Sustainable process-product development through green chemistry

ABSTRACT

Nowadays, the access to clean water is more and more difficult. Therefore, the detoxification of polluted water and its recycling when possible is mandatory for a sustainable and sustained development. For wastewater containing organic compounds at low to medium load, Catalytic Wet Air Oxidation (CWAO) yields satisfactory results, with the advantage that relatively mild operating conditions are needed, leading to lower investment and operation costs in comparison to non-catalytic WAO or other Advanced Oxidation Processes. Some activated carbons (AC) have been successfully used as catalyst in the CWAO of phenol in a trickle bed reactor (TBR) configuration. However, the reason for the catalytic activity of AC in CWAO is not yet completely understood. The aim of this research work was to fully characterising a coal-based commercial activated carbon (ME) with proven catalytic properties in the CWAO of phenol, and later, the manufacturing of an activated carbon tailored to have similar characteristics, so that it was expected to show the similar catalytic activity. Coconut shells were used as raw material for the preparation of the activated carbon by physical activation using steam (MCS). In order to increase the metal content (specifically iron) of this carbon, iron was added during the activation procedure (MCSFe). The results confirm the hypothesis that mineral matter, specifically iron, is mainly responsible for the catalytic behaviour of activated carbons in the CWAO of phenol. However, the presence of iron does not guarantee to be catalytically active in this reaction. It seems to be necessary iron to be actually available in the carbonaceous matrix and in an appropriate state.

1. Introduction

Activated carbon is a very well-known material widely used as adsorptive material for the removal of organic compounds. It has also been used for supporting catalytic metals for dedicated processes, due to its thermal and mechanical stability. Depending on the raw material used for its manufacturing and the type of activation applied (physical or chemical), some characteristics of the activated carbon, such as surface chemistry and textural properties, could be adjusted to improve its performance as adsorbent or as catalyst support. Lillo-Ródenas et al. (2005), for instance, applied activated carbons, made from Spanish anthracite through chemical and physical activation, for the adsorption of benzene and toluene. The carbons obtained had different porosity and surface chemistry, and the tests demonstrated that those with low content in oxygen surface groups have the best adsorption capacity. On the other hand, modification of manufactured activated carbons can be conducted in order to change the performance of these materials. Dastgheib et al. (2004) modified two commercial activated carbons by either acid wash, heat treatment under inert atmosphere, anhydrous ammonia treatment, or iron impregnation. All samples were tested in the adsorption of dissolved organic matter (DOM). Overall, acid wash dramatically decreased

the adsorption capacity due to significant increases in the carbon surface acidity. Heat treatment, ammonia treatment of oxidised carbons and iron impregnation increased the DOM adsorption. These latter treatments increased the carbon basicity and the accessible surface area, in addition they promoted a favourable chemistry, which resulted in an improvement of the activated carbon performance.

Another interesting and yet not widely explored application of the activated carbon is as catalyst by itself. Fortuny et al. (1998) and Tukac et al. (1998) demonstrated that some activated carbons possess catalytic activity towards the aqueous oxidation of phenol both in batch and in continuous reactors. However, actual parameters responsible for this catalytic behaviour have not been yet fully identified. According to some investigations, carbonyl type oxygen surface groups could be responsible for the catalytic activity shown by activated carbon in some reactions, for instance in the oxidative dehydrogenation of ethyl benzene (Pereira et al., 1999). On the other hand, an increase in the amount of acidic surface functionalities after nitric acid wash demonstrated to decrease the catalytic activity shown by a commercial activated carbon in the catalytic wet air oxidation (CWAO) of phenol (Santiago et al., 2005).

The aim of this study is fully characterising a coal-based commercial activated carbon (ME, Merck ref. 2514) with proven catalytic properties in the CWAO of phenol, and the subsequent manufacturing of an activated carbon tailored to have similar characteristics, so that it is to be expected to give the comparable catalytic activity. Coconut shells were used as raw material for the preparation of the activated carbon by physical activation using steam (MCS). In order to increase the metal content (specifically iron) of this carbon, iron was added during the activation procedure (MCSFe).

2. Materials and Methods

For the preparation of AC from coconut shells, one-step pyrolysis/activation with steam was conducted. Based in the results collected in the review made by Ioannidou and Zabaniotou (2007) and with the purpose of obtaining a microporous material, a high temperature was selected for the activation. Thus, the activation was done at 1000ºC in an oven. The coconut shells were heated at 10ºC/min to final temperature under nitrogen flow (500 ml/min). Once 1000ºC was reached, the inert atmosphere was replaced by a mixture of steam/nitrogen by injecting distilled water through a calibrated peristaltic pump, which was set to work at a constant flow of 0.812 ml/min. These conditions were kept for 1 hour and then the steam flow was stopped and the carbon cooled under nitrogen.

The iron-containing AC made from coconut shells was prepared in two steps. First, the raw material was heated under nitrogen up to 450ºC in order to produce a char free from volatile species and condensable oils. This char was then impregnated with a $FeCl_2 \cdot 4H_2O$ 0.1 M solution for 24 hours, and then filtered and dried overnight at 105ºC. Once moisture free, it was heated up to 1000ºC in an oven and kept at this temperature for 1 hour under a mixture of steam/nitrogen as previously described. Finally, the water flow was stopped and the AC was cooled under just nitrogen.

The coconut shell-based activated carbons and the commercial ME were crushed and sieved. Later, the 0.3-0.7 mm (50-25 mesh) size particle range was separated. The above fraction was repeatedly washed to remove all fines and oven-dried overnight at 105ºC. Then, it was stored in amber bottles until use. All samples were characterised by determining its typical physico-chemical characteristics. Surface area and porosity of the activated carbons were estimated from nitrogen isotherms at 77 K. Surface area was determined from BET equation, total pore volume from the near saturation nitrogen uptake at the relative pressure of 0.98, and micropore volume from the Dubinin-Radushkevich equation. Volume of meso- plus macropores was obtained from subtracting the micropore volume from the total pore volume. Mass titration method was used to determine the point of zero charge of each

sample. Boehm titration was carried out to determine the content and the distribution of the acidic surface functional groups. For measuring the iron concentration, samples were digested in concentrated nitric acid by a microwave digestion equipment. Dilute solutions were later analysed by AAS. The phenol adsorption isotherms were obtained at 20ºC (± 2ºC) in oxic conditions. Specifically, solutions with phenol concentrations ranging from 0.5 to 7 g/l were left in contact with 0.25 g of adsorbent. The catalytic performance was assessed for the CWAO of 5 g/l phenol solutions in a trickle bed reactor in downflow co-current at 140ºC, 0.2 MPa of oxygen partial pressure and 0.12 h of space time. The detailed description of the equipment and experimental procedure has been given elsewhere (Suarez-Ojeda et al., 2005).

3. Results

Table 1 summarises the liquid and solid products rendered during the manufacture of the activated carbons. The liquid product yield in sample MCS, made from coconut shells and by one-step pyrolysis activation, was higher than that obtained for MCSFe. This is attributed to the carbonisation step that was conducted before the iron impregnation step and the activation. In the manufacturing of the chars that were later used in the iron impregnation, the liquid products yield was about 70%. For that reason, after the iron impregnation and the activation with steam, the liquid product yield was only about 10%, because most of the organic material that is later released as oils was already eliminated in the char production step.

Table 1. Yields obtained in the manufacturing of activated carbons.

Sample	Solid product (% wt)	Liquid product (% wt)	Gas + losses (% wt)
MCS	19.0	35.4	45.6
MCSFe	56.4	10.4	33.2

The physical characterisation of both coconut-based activated carbons, MCS and MCSFe are listed in Table 2. MCS is a highly microporous carbon since 96% of its total porosity is in the micropore range. The surface area is also relatively high, which indicates that steam was effective as activating agent promoting the formation of micropores. Sample MCSFe, on the contrary, showed a surface area 40% lower than MCS and also 47% lower micropore volume. Despite the iron is supposed to enhance the gasification of the carbon, thus promoting the porosity, in this case the iron impregnated on the char made from the coconut shells could have prevented the water and the char from interacting and thus from reacting. As a result, development of the surface area and microporosity were suppressed and only superficial reactions, typically producing mesoporosity, promoted. Actually, some increase in the mesopore volume, from 4% to 9%, was observed in sample MCSFe (Marsh and Rodríguez-Reinoso, 2006; Alcañiz-Monge et al., 2007).

Table 2. Physical properties of tailored activated carbons.

Sample	SA_{BET} (m^2/g)	V_{mic} D-R (cm^3/g)	$V_{mes+mac}$ (cm^3/g)	V_{tot} (cm^3/g)
ME	1261	0.473	0.137	0.610
MCS	830	0.369	0.014	0.383
MCSFe	493	0.194	0.020	0.214

The surface oxygen content measured by Boehm titrations, the pH_{pzc} and the iron content of the manufactured carbons are collected in Table 3. The coconut based carbons show not detectable amount of carboxylic functionalities. Also, the content of other functional groups like lactones and phenolics is lower than the content of commercial ME. This could be explained by the fact that, after the activation, the samples were left to freely cool from 1000ºC until room temperature under just the nitrogen flow, so most of the acidic surface functionalities were probably decomposed into CO and CO_2 during cooling.

Table 3. Chemical properties of tailored activated carbons.

Sample	Phenolics (meq/g)	Lactones (meq/g)	Carboxyls (meq/g)	pH_{pzc}	Fe content (%wt)
ME	0.097	0.123	0.031	7.36	0.40
MCS	0.059	0.033	0.000	10.82	0.00
MCSFe	0.017	0.042	0.000	10.52	0.20

The phenol adsorption isotherms of the tailored carbons are presented in Figure 1. Sample MCS showed high adsorption capacity at bulk phenol concentration values higher than 5000 mg/L , whereas for lower values it is in the same order than the commercial ME. However, sample MCSFe gave a considerable decrease in the phenol adsorption capacity, i.e. a loss of 74% in its original adsorption capacity. As it has been reported in the literature (Dabrowski et al., 2005), surface chemistry is determinant in the activated carbon performance as adsorbent for phenol. Low content of acidic surface functionalities lowers the hydrophilicity of the carbon surface, avoiding the formation of water clusters and improving the interaction of the phenol molecules with the carbonaceous structure. All these effects enhance the phenol adsorption on activated carbons. Since MCS and MCSFe have very similar oxygen content (see Table 3), the decrease of the adsorption capacity should be attributed to the considerable difference in both the surface area and the micropore volume as seen in Table 2.

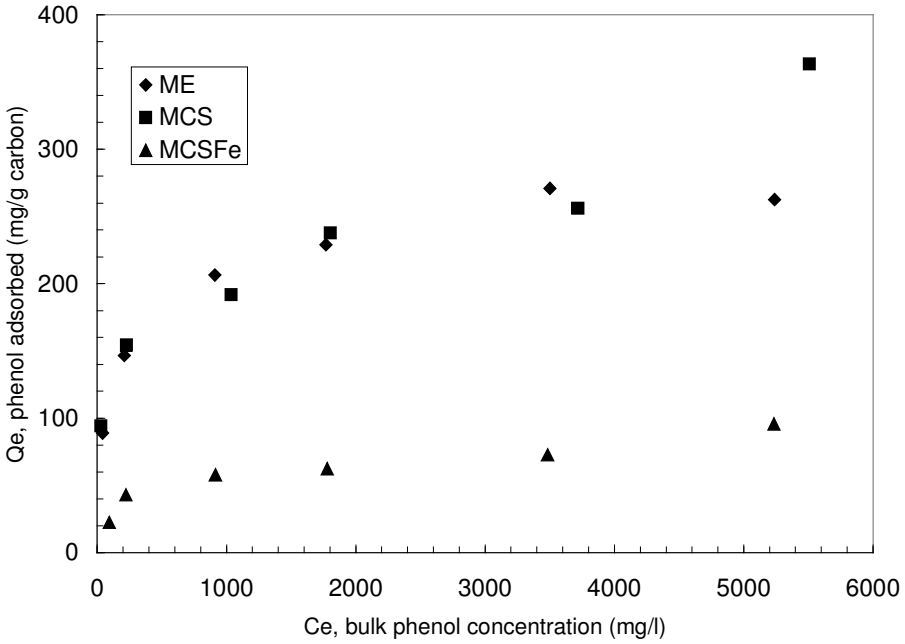

Figure 1. Phenol adsorption isotherms over tailored activated carbons at 20ºC.

The phenol conversions obtained with these tailored carbons in the TBR tests are shown in Figure 2. Regardless of the iron content of sample MCSFe, which is half that of ME (see Table 3), the conversion achieved with MCSFe is considerably much more lower, only 10% compared to 45% given by ME. The poor catalytic activity exhibited by MCSFe could be attributed to the very low value of both surface area and micropore volume developed during its activation. Actually, the value of phenol conversion obtained with MCSFe is practically the same observed for MCS, which suggests that both MCS and MCSFe are affected by serious problems of surface availability. When measuring the amount of acidic compounds formed as intermediates from the phenol oxidation with these carbons as catalysts, some noticeable observations can be made. With carbon MCS, 33% of the intermediates were acids. This is a quite low mineralisation that correlates with its poor catalytic performance. However, the amount of acidic intermediates considerably increased when iron was incorporated to the carbon, MCSFe, up to 88%, for which the increase of phenol conversion, compared to MCS, is only from 8% to 10%. Commercial ME also shows a high selectivity towards acidic intermediates, thus 94% of the compounds in the exited effluent are acidic.

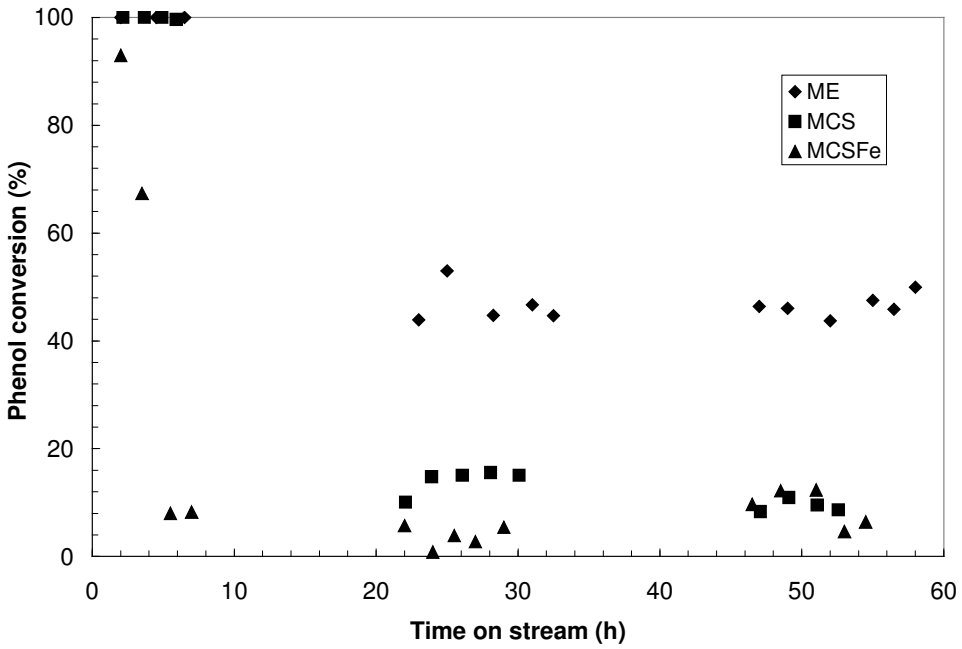

Figure 2. Phenol conversion in TBR using tailored manufactured samples, at 140ºC, 2 bar of oxygen partial pressure and 0.12 h of space time.

Leaching of iron was found for ME and MCSFe. The iron content in the used activated carbons after 55 hours on stream are listed in Table 4. As well, the weight gained by the AC bed, ΔW, of all three carbons, the pH and the iron concentration in the exited effluent at the end of the run are given. The leaching was about 80% for sample MCSFe. Since the iron in the liquid is measured in the last sample taken from the reactor, and the value measured in the case of MCSFe is very low compared with the one measure in the liquid when using ME, which in contrast only lost 22% of its original iron, it is possible to think that most of the leaching could be occurring during the first hours of operation. Zhu et al. (1997) proposed that during carbonisation step, iron atoms migrate from the surface to the inner part of the bulk of carbon particles. This migration depends on the temperature of the carbonisation. Also time could be affecting the iron migration in the carbon, however the effect of this parameter has not been reported. For MCSFe, the iron impregnation was done before the activation, but after the carbonisation step. The textural properties of the char could be affecting the proposed iron migration, remaining most of it on the surface, where it probably cannot be properly fixed in the carbonaceous matrix, which facilitates leaching. The ΔW after

55 hours of operation can probably be assigned to the deposition of phenolic polymers over AC surface due to condensation by oxidative coupling. Also, the oxidative coupling products could be responsible for the increase observed in ΔW.

.

Table 4. Weight difference in ME and tailored manufactured samples after operation in TBR and final pH of liquid stream.

Sample	ΔW (g)	Final pH	Fe in the outlet effluent (mg/L)	Fe content after use (% wt)
ME	2.519	2.13	9.9	0.31
MCS	2.900	3.85	0.0	0.00
MCSFe	2.051	2.96	0.3	0.04

4. Conclusions

One-step pyrolysis procedure was effective to manufacture activated carbon from coconut shells, MCS, achieving high values of surface area and well developed porosity, although most of the porous being in the range of microporosity. MCS carbon, despite having 34% lower surface area, shows the same adsorption capacity than commercial carbons like ME made from coal. However, due to the absence of mineral matter in the raw coconut shells, carbon MCS did not show little catalytic activity for CWAO of phenol. Sample MCSFe, made also from coconut shells but with an additional iron impregnation step included before the activation, also showed poor catalytic behaviour. This indicates that the iron in sample MCSFe is not catalytically active. In conclusion, the presence of iron in the carbonaceous materials does not always guarantee catalytic activity, probably due to the position or even the crystalline phase in which it is present.

Abstract

This study focuses on the roles played by three major functional groups (amine, carboxyl and hydroxyl) in the orange waste biomass for sorption of three heavy metals (Cd^{2+}, Zn^{2+} and Cr^{3+}). The biosorbent was chemically modified to block the mentioned functional groups in order to determine their contribution to the adsorption of metals. Fourier transform infrared (FTIR) and solid state carbon-13 nuclear magnetic resonance (^{13}C-NMR) spectroscopy were used to investigate the chemical modification. Additionally, batch biosorption tests were carried out with the different biosorbents in order to determine the possible reduction in metal uptake with the chemically modified biosorbent. Blocking of the COOH groups by chemical esterification resulted in an important reduction in metal binding. Nevertheless, no significant modification in metal removal was observed with acetylated and methylated orange waste.

Introduction

The increase in industrial activities has intensified environmental pollution and the deterioration of some ecosystems, with the accumulation of pollutants such as heavy metals, synthetic compounds, etc. The pollution by heavy metals is of great corcern due to potential health hazard caused by these compounds to the environment.

Therefore, an adequate treatment of the polluted wastewater are required. Traditional treatment techniques include chemical precipitation, membrane filtration, electrolysis, ion exchange, carbon adsorption and co-precipitation/adsorption. Nevertheless, the application of such processes is sometimes restricted because of technical or economic constraints.

The search for new technologies involving the removal of toxic metals from wastewaters has directed attention to biosorption, based on the metal binding capacities of various biological materials. Among these materials, fruit waste materials are tipically generated in large quantities by the fruit juice industry as a waste by-product and they have demonstrate their ability to remove heavy metals in solution. Pectin has been identified as an important component of citrus wastes and has been found to have great affinity for metal ions.

Even though orange waste has been recently used as adsorbent in many studies, the biomass–metal binding mechanisms are not well understood. In order to investigate the adsorption mechanism, chemical modifications to orange waste were performed to indirectly determine the ligands on the biomass responsible for metal binding. Sorption test, with the different biomass, in combination with FTIR spectrometric and ^{13}C-NMR studies were carried out to investigate the participating functional groups.

Materials and methods.

Biomass conditioning

The orange waste used as adsorbent was obtained from orange juice industry. The material was cut into small pieces, was extensively washed with tap water and was oven-dried at 50-60 ºC until constant weight. The washed and dried material was crushed and sieved to obtain a particle size lower than 1.5 mm.

Chemical modification of the biomass

The following treatments (Kapoor and Viraraghavan, 1997) were carried out on orange waste:

Chemical esterification. The carboxyl group of the biomass was methanol esterified. Esterification was carried out by heating 9 g of biomass in 633 mL of 99.9% pure methanol and 5.4 mL of concentrated hydrochloric acid (HCl), given a final acidic concentration of 0.1 M HCl, under reflux for 48 h. Then the esterified biomaterial was thoroughly washed with distilled water, filtered and dried. The general reaction scheme of this treatment is:

$$RCOOH + CH_3OH \xrightarrow{H^+} RCOOCH_3 + H_2O$$

Chemical methylation. The modification of amino group was made by shaking, at ambient temperature, 9 g (dry weight) of the raw biomass in 180 mL of formaldehyde (HCHO) and 360 mL of formic acid (HCOOH) for 6 h at 125 rpm. Then the treated biomaterial was thoroughly washed with distilled water, filtered and dried. This treatment resulted in methylation of amino group. The general reaction scheme is:

$$RNH_2 + 2HCHO + 2HCOOH \longrightarrow RN(CH_3)_2 + 2CO_2 + 2H_2O$$

Chemical acetylation. Total acetylation of amino and hydroxyl groups of the sorbent was carried out by refluxing the biomass suspension in acetic anhydride at 80 ºC for 10 h. Then the acetylated biomaterial was thoroughly washed with distilled water, filtered and dried. The general reaction scheme of this treatment is:

$$RNH_2 + CH_3COOH \longrightarrow RNHCOCH_3 + H_2O$$

$$RCH_2OH + CH_3COOH \longrightarrow RCH_2OCOCH_3 + H_2O$$

Sorption assays

Adsorption studies were carried out by batch process. 0.2 g of biomass were added to glass flasks containing 50 mL solution of metal ion (Cd^{2+}, Zn^{2+} or Cr^{3+}) of the desired concentration. The mixture was stirred magnetically for the time neccesary to reach equilibrium (3 h for Cd^{2+} and Zn^{2+}, and 3 days for Cr^{3+}). The pH of solutions was adjusted to 4, by adding small amounts of dilute solutions of HNO_3 and NH_3. After the contact time, the biosorbent was removed by filtration through glass fibre prefilters (Millipore AP40) and the filtrates were analysed for residual metal concentration by atomic absorption spectrophotometry (Perkin Elmer model AA300). Batch experiments were performed by varying the initial concentration of metal from 0 to 300 mg/L. All experiments were conducted in duplicate. The metal percentage removal and the biomass sorption capacity were calculated in each case.

Cd^{2+}, Zn^{2+} and Cr^{3+} sorption equilibrium data onto raw orange waste were fitted to Langmuir isotherm in order to obtain the maximum sorption capacity and to be able to compare the sorption properties of this material with other adsorbents in bibliography.

FTIR spectra and ^{13}C-NMR study

FTIR and ^{13}C-NMR spectra were used to analyse the functional groups in the raw as well as chemically modified biomass. FTIR spectra were recorded in a Fourier transform infrared spectrophotometer (Perkin Elmer 16F PC) with the samples prepared as KBr discs. ^{13}C-NMR spectra were recorded at the Complutense University of Madrid, Spain, on a Bruker WB-400 spectrometer.

Results and discussion.

FTIR analysis results

FTIR spectra of raw and chemically modified orange waste (OW) are shown in Figure 1.

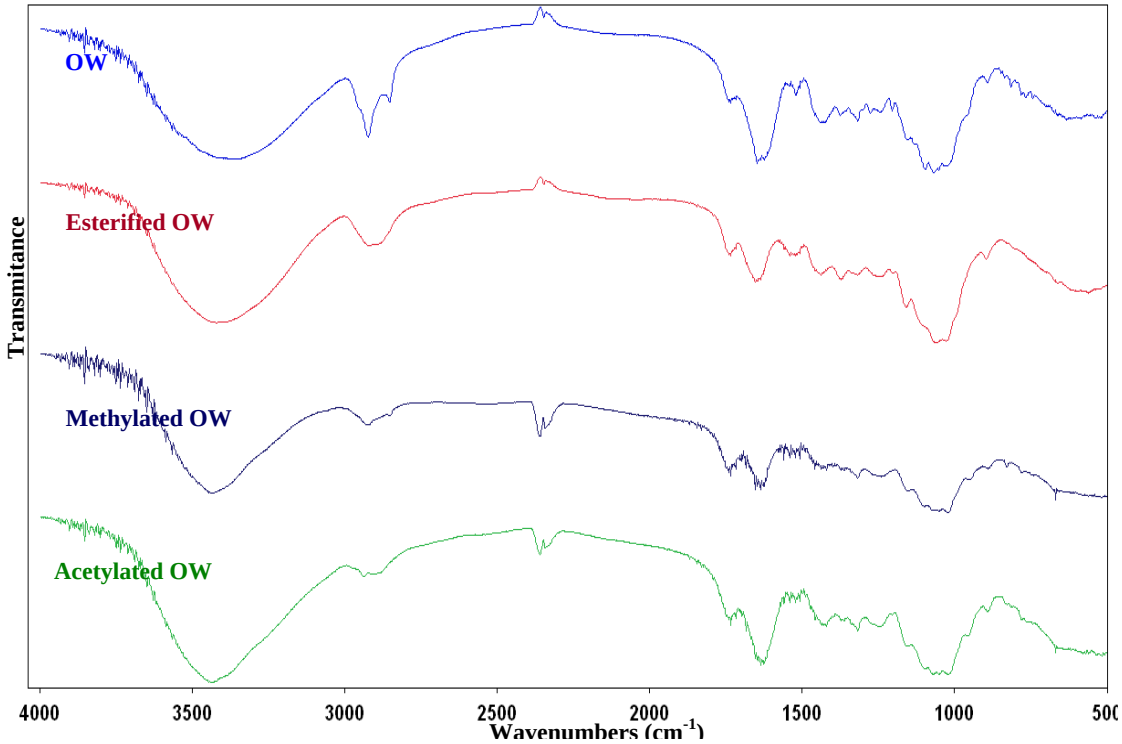

Figure 1. FTIR spectra of raw and chemically modified orange waste.

The spectra of orange waste display a number of adsorption peaks, indicating the complex nature of the material examined. The FTIR spectra of raw biomass exhibits a broad peak between 3200 cm^{-1} and 3600 cm^{-1} which is indicative of the existence of macromolecular assotiation (cellulose, pectin, etc.) and might be the indication of both amine and bonded OH groups. The finger print region of 1000-1200 cm^{-1} exhibits the characteristic peaks of cellulose. Bands around 1647 cm^{-1} and 1736 cm^{-1} are indicative of free and esterified carboxyl groups, respectively, which may be useful in identifying pectins.

The shift in wavenumbers at 1636 cm^{-1} in esterified biomass corresponds to a change in bonding energy associated with a modification in carboxyl groups on cellulose or pectin chains.

The band observed at 3357 cm^{-1} in raw material got widened in acetylated and methylated biomass. It suggests changes in the amine groups present in the biomass and, in the case of acetylated orange waste, the change could be also due to hydroxyl groups. The increase in the band at 1716 cm^{-1} in methylated biomass indicates the presence of formic acid.

^{13}C-NMR analysis results

Figure 2 shows the ^{13}C-NMR spectrum of raw material and chemically modified biomass.

^{13}C-NMR spectrum of raw material are similar to those obtained for other authors for this type of material (Javis et al., 1996). The characteristic bands at 105 ppm (C-1), 84 ppm (C-4), 72-75 ppm (C-2, C-3 and C-5) and 65 ppm (C-6) are assigned to cellulose. Related to hemicellulose signal at 101 ppm (C-1), 89 ppm (C-4) and 62 ppm (C-6) are observed and peaks at 101 ppm (C-1), 80 ppm (C-4) and 71 ppm (C-2, C-3) are attributed to pectins. Besides these peaks, signals attributed to carboxyl groups in

their ionized (177 ppm) and esterified (165 ppm) form, methoxyl carbon (56 ppm), methylene carbon (33 ppm), acetyl carbon (23 ppm) and methyl carbon (19 ppm) were also obtained.

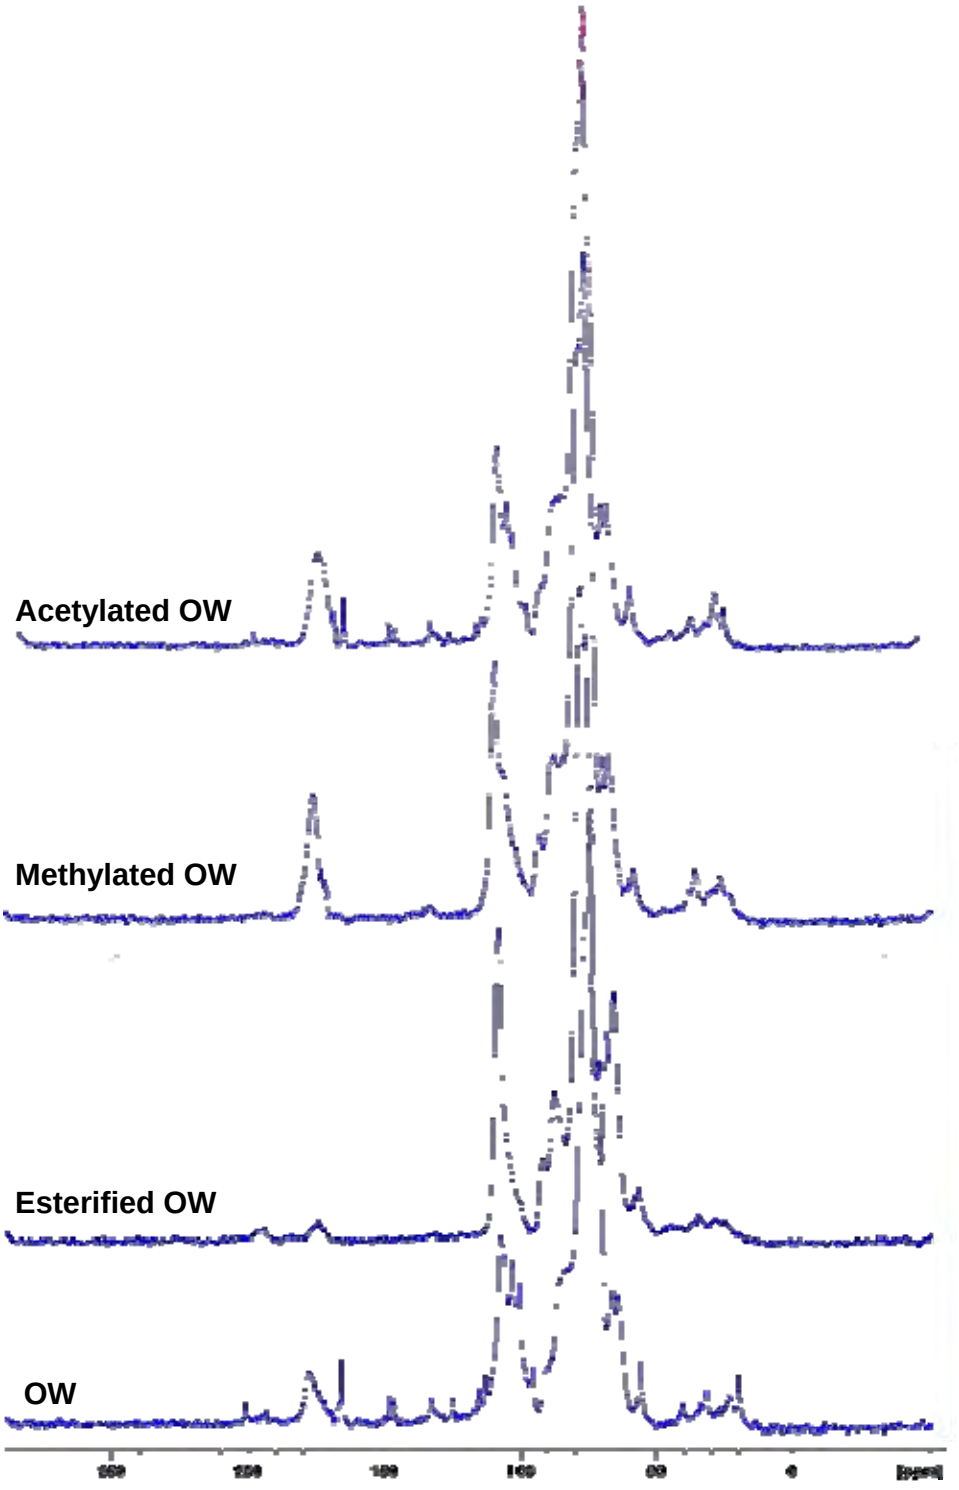

Figure 2. ^{13}C-NMR spectra of raw and chemically modified orange waste.

After esterification treatment, signal at 177 ppm disappears and, contrary to that we expected, the band at 165 ppm is considerably reduced. This unexpected result could be explained by the pectins extraction, and consequently the disappearance of carboxylic groups present in them, with this treatment. In fact, several authors have

studied the extraction of pectin by heating in acid conditions (May, 1990).

An increase in peaks at 38 ppm and 23 ppm was obtained with the methylation and acetylation treatments, respectivately. This fact is indicative of the presence of amine and hydroxyl groups.

Thus, correlating the data obtained from FTIR and ^{13}C-NMR spectra it could be concluded that carboxyl, amine and hydroxyl groups are present in the studied biomass and they have been modified chemically. So, all these groups might be responsible of metal uptake.

Sorption assays

Batch sorption tests were carried out with both, raw and chemically modified biomass, to compare the biosorption efficiency and hence the contribution of active compounds existing on the biomass. The sorption uptake by raw biomass and modified biomass are compared in Figure 3

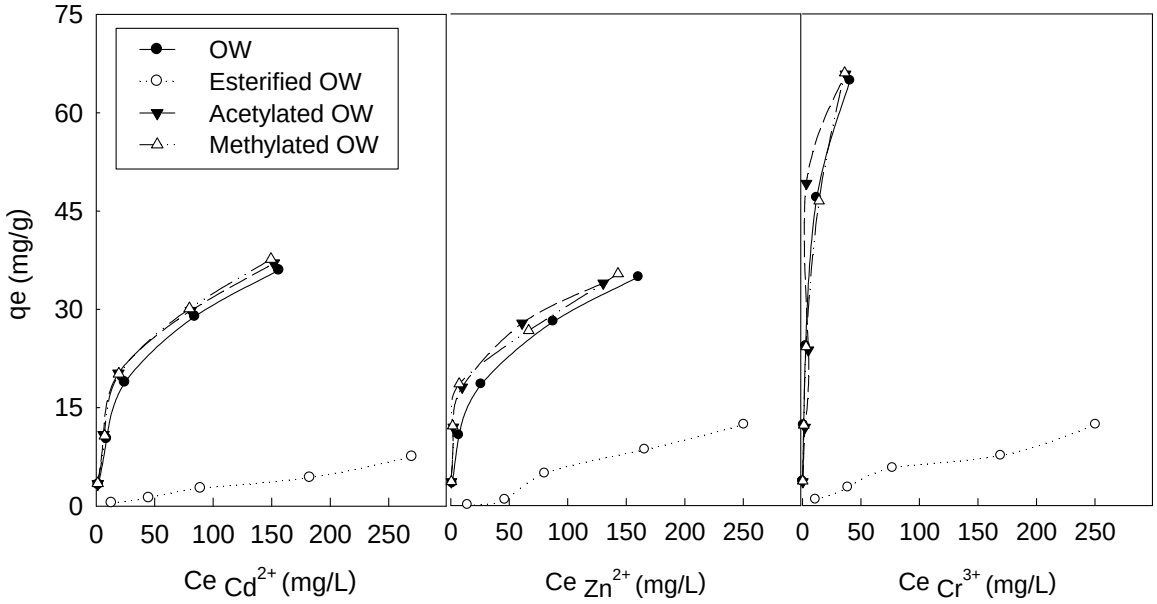

Figure 3. Effect of chemical modification of orange waste on Cd^{2+}, Zn^{2+} and Cr^{3+} biosorption.

As it can be seen, the lowest metal uptake was obtained with esterified biomass. Biosorption of cadmium, zinc and chromium was almost inhibited with the esterification treatment, when pectins were extracted from raw materials and carboxyled groups were esterified, thus indicating the important role played by pectins and carboxyl groups in the biosorption of heavy metals onto orange waste. The reductions in percentage removal of metals with the esterification treatment, in comparison with raw material, were higher than 79%, 66% and 82% for Cd, Zn and Cr, respectively. No significant modification in biosorption were observed in acetylated and methylated biomass, so these functional groups do not seems to be involved in metal uptake by orange waste.

A good correlation of equilibrium data for raw material was obtained by Langmuir isotherm. The maximum sorption capacity are 41.2 mg/g, 40.9 mg/g and 72.5 mg/g for Cd^{2+}, Zn^{2+} and Cr^{3+}, respectively. These values are within the range of other materials that have been described in bibliography as promissing biosorbent for removal heavy metals (Table 1).

Table 1. Maximum sorption uptake for different materials (Volesky, 2004).

Material	Metal	Maximum sorption uptake ($mg \cdot g^{-1}$)
Bacillus biomass	Cr^{3+}	118
Rhizopus arrhizus	Cr^{3+}	31
Candida tropicalis	Cr^{3+}	4.6
Sargassum species	Zn^{2+}	70
Candida tropicalis	Zn^{2+}	30
Bacillus sp.	Zn^{2+}	3.4
Sargassum natans	Cd^{2+}	135
Candida tropicalis	Cd^{2+}	60
Rhizopus arrhizus	Cd^{2+}	19

Conclusions

Modification of orange waste biomass was performed using various kinds of chemical reagents in order to verify the contribution of different functional groups on the biosorption of Cd^{2+}, Zn^{2+} and Cr^{3+}. FTIR and ^{13}C-NMR analysis of raw and modified orange waste disclosed the existence of carboxylic, amine and hydroxyl functional groups and pectins on the biomass. Sorption studies demonstrated that the esterification treatment resulted in the decrease of biosorption capacity of the biomass, which suggested that the eliminated pectins and the carboxylic groups existed in the biomass are major component and functional groups involved in biosorption process. They play an important role in the biosorption of studied metal onto orange waste. The acetylated or methylated biomass do not provided significant differences in sorption uptake, when comparing with raw biomass, which indicates that amine and hydroxyl groups have negligible effect on metal sorption onto orange waste at the studied experimental conditions. The biosorption process of raw biomass has been described by Langmuir isotherm and it has been demonstrated that maximum sorption capacity of orange waste are within the range of other materials that have been previously described in bibliography as promissing biosorbents for heavy metals removal.

Keywords: Mercury, Removal, ETS-4, Activated carbon
Topic: Sustainable process-product development through green chemistry

Abstract

ETS-4 titanosilicate and activated carbon were investigated and compared for removal of trace amounts of mercury (II) from contaminated aqueous solutions. Isothermal batch stirred experiments were performed using a batch factor of 250 mL mg^{-1} and an initial Hg^{2+} concentration of 50 µg L^{-1}. ETS-4 titanosilicate exhibited much higher mercury removal capacity (~12 mg g^{-1}) than activated carbon (~5 mg g^{-1}). However, Hg^{2+} removal by activated carbon is faster, which was confirmed by pseudo first-order and pseudo second-order rate models. This study revealed that the removal of Hg^{2+} by ETS-4 titanosilicate and activated carbon from solutions with low metal levels is quite different and that ETS-4 titanosilicate is more efficient.

1 Introduction

Considered by EPA and by the European Water Frame Directive as a priority pollutant, mercury (Hg) is one of the most hazardous heavy metals present in the environment. Due to its toxic effects on aquatic life, human beings and environment, increasing attention has been given to the removal of Hg from effluents, in such a way to satisfy the actual strict environmental regulations.

Microporous titanosilicates are novel materials which were found to have valuable properties for the decontamination of mercury (II) polluted waters (Lopes et al., 2007). The question is: are they good enough to replace typically used adsorbents in water purification processes such as commercially available activated carbon?

Activated carbon is perhaps one of the most common and widely used adsorbents for uptaking noxious substances from water. Several studies have reported the successful application of activated carbons to remove pollutants from waters and wastewaters (e.g. Mohan et al., 2001; Krishnan and Anirudhan, 2002; K. Ranganathan, 2003; Jusoh et al., 2007; Vreysen et al., 2008).

The main objective of this study is to assess and compare the Hg^{2+} removal capacity of ETS-4 titanosilicate and activated carbon from solutions with low metal levels, in order to evaluate if microporous materials, such as ETS-4 are competitive with respect of commercial adsorbents, such as activated carbon.

2 Experimental

[1] Corresponding author. Tel + 351-234-370737. E-mail: claudia.b.lopes@ua.pt

All chemicals reagents used in the work were of analytical reagent grade and obtained from chemical commercial suppliers, without further purification. The certified standard stock solution of mercury (II) nitrate (1000 mg L^{-1} Hg^{2+}) was purchase from BDH Chemicals Ltd.

ETS-4 titanosilicate was synthesised according to the procedure described in Lopes et al. (2007, 2008) and the activated carbon (*Chemviron Pulsorb FG4 type*) was kindly supplied by *Chemviron Carbon*. The characteristic properties of these materials are depicted in Table 1. The particle size of ETS-4 was determined from the scanning electron microscope images obtained by a Hitachi S-4100 microscope and the pore size was calculated from the framework data. The activated carbon characteristics shown in Table 1 are those given by the *Chemviron* product bulletin.

Table 1. Properties of ETS-4 titanosilicate and activated carbon (*Chemviron Pulsorb FG4 type*).

	ETS-4	Chemviron Pulsorb FG4 type
Formula	$[(Na)_9Ti_5Si_{12}O_{38}(OH).12H_2O]$	---
Physical form	white powder	black powder

Particle diameter (µm)	0.5-0.9	30
Pore size (nm)	0.4	---

**Brunauer, Emmett and Teller, 1938. J. Am. Chem. Soc., 60: 309.*

In order to compare ETS-4 titanosilicate and activated carbon efficiencies on Hg^{2+} removal from solutions with low metal levels, batch stirred sorption experiments were isothermally (21±1ºC) carried out. Each batch experiment was performed using 8 mg of material (ETS-4 or activated carbon *Chemviron Pulsorb FG4 type*) and 2 L of 50 µg L^{-1} Hg^{2+} solution. The solution-powder suspension was magnetically stirred at 1000 rpm. In order to determine the mercury concentration in solution along time, samples were withdrawn at increasing times, filtered through a Millipore membrane (0.45 µm), acidified to pH<2 with HNO_3 "Hg free", and then analysed by cold vapour atomic fluorescence spectroscopy (CV-AFS), on a PSA cold vapour generator, model 10.003, associated with a Merlin PSA detector, model 10.023, and using $SnCl_2$ as reducing agent. A Hg^{2+} control solution (50 µg L^{-1}) was always run in parallel under the same experimental conditions.

For each material, the concentration curves of the remaining mercury in solution versus time were obtained. The amount of mercury removed by the materials at a given time, q_t (mg g^{-1}), was calculated by the mass balance:

$$q_t = (C_0 - C_t)\frac{V}{M} \quad (1)$$

where C_0 (µg L^{-1}) is the initial concentration of mercury in the liquid-phase and confirmed by the control solution, C_t (µg L^{-1}) is the mercury liquid-phase concentration at a certain time (t), V the volume of the solution (L) and M the material dry mass (mg).

In order to compare the kinetic performance of both materials, the experimental results were fitted with pseudo first-order Lagergren (Lagergren, 1898) and the pseudo second order kinetic equations (Ho and McKay, 1999). These are empirical rate equations commonly used to describe the kinetics of sorption (Ho and McKay, 1999; Reddad et al., 2002; Zhang et al., 2005), which are based on the overall sorption rate.

The Lagergren rate expression is generally expressed as follows (Lagergren, 1898):

$$\frac{dq_t}{dt} = k_1(q_e - q_t) \tag{2}$$

where q_t (mg g^{-1}) is the amount of mercury sorbed onto the material at time t (h), and k_1 (h^{-1}) is the rate constant of first-order sorption. After integrating and applying boundary conditions, t=0 to t=t and q_t=0 to q_t= q_e, one obtains:

$$\log(q_e - q_t) = \log q_e - \frac{k_1}{2.303}t \tag{3}$$

The validity of the model is shown by the linear trend observed when graphing experimental $log\ (q_e - q_t)$ as a function of t, so the rate constant (k_1) may be found from the corresponding slope and the intercept should match the q_e value previously introduced.

The pseudo second-order equation, as the pseudo-first order one, is also based on the sorption capacity of the solid phase and, in contrast with the first model, it usually predicts the behaviour over the whole range of adsorption (Namasivayam et al., 1998; Ho and McKay, 1999) and no parameter has to be known beforehand:

$$\frac{dq_t}{dt} = k_2(q_e - q_t)^2 \tag{4}$$

where k_2 (g mg^{-1} h^{-1}) is the second-order sorption rate constant. For the boundary conditions, t=0 to t=t and q_t=0 to q_t= q_e, the integrated form of Eq. (4) is:

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{1}{q_e}t \tag{5}$$

If the second-order kinetics model is applicable, the plot of t/q_t versus t should be linear and k_2 and q_e may be found from the corresponding intercept and slope.

3 Results and discussion

The concentration of mercury in solution along time (C_t) and the corresponding amount of mercury removed by each material (q_t) are shown in Figure 1.

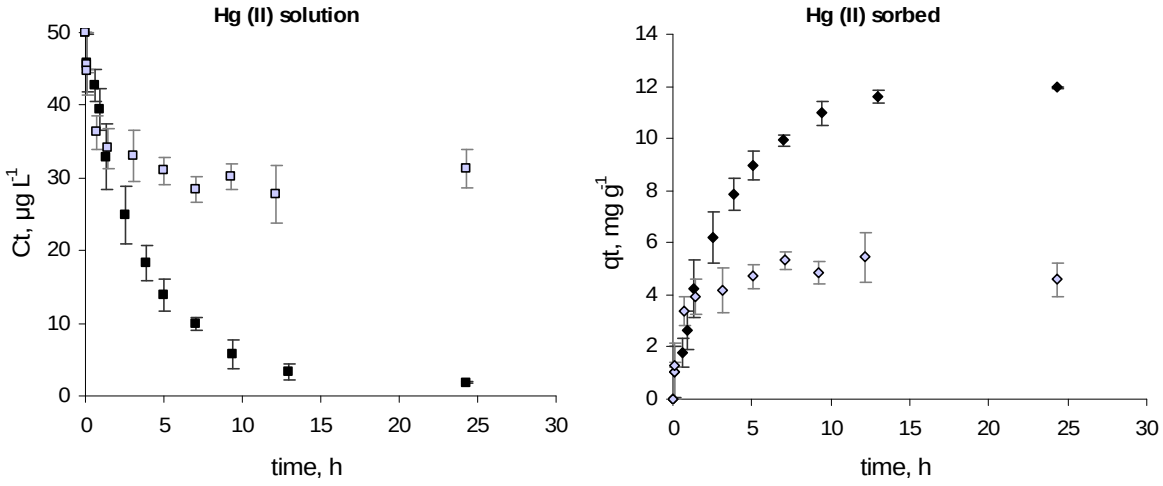

Figure 1: Mercury concentration in the liquid phase (C_t) and removrd (q_t) by ETS-4 (black symbols) or on activated carbon (grey symbols) as function time.

For both materials the Hg^{2+} concentration in the liquid phase decreases with time until the equilibrium, from when mercury concentration in solution remains the same. However, it is

clear that the two materials have distinct ability to remove Hg^{2+} under the current experimental conditions. For the initial Hg^{2+} concentration of 50 µg L^{-1}, which is the limit value for discharges from industrial sectors other than the chlor-alkali electrolysis industry, in accordance with Directive 84/176/EEC, and using only 8 mg of material, ETS-4 has demonstrated to have much higher capacity to remove Hg^{2+} from solutions than activated carbon. At the equilibrium, the amount of Hg^{2+} removed by ETS-4 is almost three times higher than onto activated carbon (Table 2). Moreover, at the equilibrium, after 24 hours treatment with ETS-4, it was possible to get clean water, of drinking quality since the residual Hg^{2+} concentration (Table 2) was below of the allowable limits for mercury ([Hg] ≤ 2 µg L^{-1}) (http://www.inspect-ny.com/water/levels.htm). In contrast, when using activated carbon *Chemviron Pulsorb FG4 type* the Hg^{2+} concentration remaining in solution was quite above the limits of clean drinking water (Table 2).

Table 2. Hg^{2+} concentration in solution at the equilibrium (C_e, µg L^{-1}), experimental sorption capacity (q_e, mg g^{-1}) and removal percentage (%) after 24h.

Material	C_e, µg L^{-1}	q_e, mg g^{-1}	% removal
ETS-4	1.79 ± 0.11	12.0 ± 0.1	96.4 ± 0.2
Activated carbon	31.4 ± 2.6	4.6 ± 0.6	37.2 ± 5.2

The first-order rate constant (k_1) and the second-order rate constant (k_2) were calculated from the plots shown in Figure 2. The corresponding kinetic sorption rate constants k_1 and k_2 together with the R-squared (R^2) of fittings, which indicate the quality of the regressions, are depicted in Table 3 together with the experimental and calculated q_e.

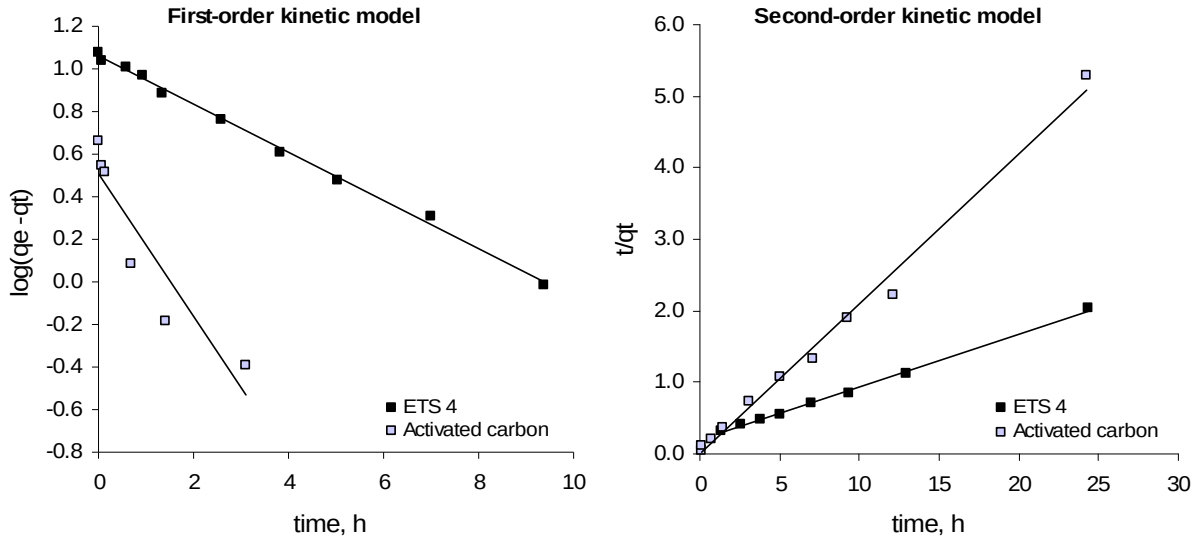

Figure 2. Pseudo first-order Lagergren and pseudo second-order plots for the removal of mercury from solution by the ETS-4 (black symbols) and by activated carbon (grey symbols).

For ETS-4 the correlation coefficients are the same for the two models (Table 3), which indicates that both of them describe the experimental kinetic results of the Hg^{2+} removal appropriately. However, there is a better agreement between the experimental q_e value and the value given by the first-order kinetic model. For activated carbon the sorption kinetic is better described by the second-order model, supported by the correlation coefficient and by the comparison between the experimental and fitted q_e values.

As it may be seen by the kinetic constants, activated carbon displayed faster mercury sorption kinetics than ETS-4. Although the equilibrium was reached in a shorter time when using activated carbon than ETS-4, both the fitted and experimental q_e obtained by using ETS-4 are higher than those obtained by the activated carbon.

Table 3: Kinetic sorption rate constants, k_1 (pseudo first-order Lagergren) and k_2 (pseudo second-order), together with experimental and calculated q_e, and the corresponding R-squared (R^2) of the fittings.

		First-order kinetics			Second-order kinetics		
	q_e-exp (mg g^{-1})	k_1 (h^{-1})	R^2	q_e-fitted (mg g^{-1})	k_2 (g mg^{-1} h^{-1})	R^2	q_e-fitted (mg g^{-1})
ETS-4	11.95	0.260	0.997	11.48	0.03	0.997	13.51
Activated carbon	4.60	0.772	0.858	3.22	5.46	0.992	4.78

4 Conclusions

The behavior of ETS-4 and activated carbon when removing mercury (II) from solutions with low metal levels has been evaluated and compared. According with the results obtained in this study both materials are able to remove Hg^{2+} from solution, even at low initial concentrations, although they display different uptake capacity. ETS-4 titanosilicate is much ore efficient than activated carbon as it is able to remove more than 96% of mercury from solution (C_0 = 50 µg L^{-1}) and to remove around 12 µg mg^{-1} of mercury after 24 hours. Activated carbon has a lower sorption capacity (~ 5 µg mg^{-1}) but a faster mercury sorption kinetics. It is worth to highlight that ETS-4 allows to purify Hg^{2+} contaminated water up to drinking quality water, so this material may be considered as a very efficient cleaning agent.

Keywords: bioleaching, acidophiles, chalcopyrite, lead concentrates
Topic: Integration of life sciences & engineering

Abstract

Biometallurgy can be defined as the field of applications resulting for the control of natural (biochemical) processes of interactions between acidophilic bacteria populations and minerals to recover valuable metals. This work concerns to the screening of the bioleaching potential of a indigenous microbial consortium (Achada Sludge – AS), collected at the abanboned S. Domingos copper mine, for using on metals bioleaching and recovery of two different mineral concentrates: a rich copper concentrate (chalcopyrite) and a lead concentrate (Pb-concentrate). For copper concentrate, the highest metals recoveries were found for 1% chalcopyrite with 41% Fe, 30% Cu and 75% Zn after 1 week of enrichment, reaching a recovery of 92% Fe, 92.5% Cu and 100% Zn after 1 month of enrichment. The best bioleaching results for Pb-concentrate were obtained for 2% substrate, with a % metals recovery of 44% Fe, 22% Cu and 100% Zn after 2 weeks of enrichment, and reaching a recovery of 65% Fe, 82% Cu and 100% Zn after 2 months of enrichment. Microbial population characterization was performed using 16S rRNA approach.

1 Introduction

Application of microbial processes by the mineral industry - biohydrometallurgy - predates the understanding of the role of microorganisms in metals extraction, commonly referred to as bioleaching (Olson et al., 2003). Biohydrometallurgy, an interdisciplinary field involving geomicrobiology, microbial ecology, microbial biochemistry, and hydrometallurgy, it is now a well biotechnology alternative for treating specific mineral ores with distinctive advantages over traditional mining (Valenzuela et al., 2006).

Bioleaching exploits the ability of microbes that thrive in high acid environments, require inorganic food and energy sources and frequently display resistance to heavy metals. These unique chemoautotrophic bacteria have the primary roles in acceleranting sulfide mineral dissolution (Ghauri et al., 2007) and are extensively used for industrial applications. The costs associated with maintenance of sulfide bioprocessing microorganisms are minimal because many gain energy from the redox reactions, utilize carbon dioxide from the air as C source and obtain their phosphorus, nitrogen, potassium and micronutrients from the bioleach environment (Watling, 2006).

Two different bacteria types (mesophilic and thermophilic) are most important in bioleaching of sulphide metals. Currently, these two types of bacteria have been playing a major role in industrial bioleaching applications. The mesophilic iron- and/or sulphur-oxidising bacteria, notably *Acidithiobacillus ferrooxidans*, *Acidithiobacillus thiooxidans* and *Leptospirillum ferrooxidans* are the most extensively used microorganisms within the mining and metallurgical industries for the oxidation of sulphide minerals. These bacteria derive the energy required for their growth and other metabolic functions from the oxidation of inorganic materials such as sulphide ores/concentrates (Akcil, 2004).

Commercial bioleaching initially involved copper concentrates; however, new processes have been developed for the extraction of other metals. It has been shown that

microorganisms can extract cobalt, nickel, cadmium, antimony, zinc, lead, gallium, indium, manganese, copper, and tin from sulphur-based ores (Rawlings, 2002, 2005;Rodríguez et al., 2003; Olson et al., 2003; Ndlovu, 2008).

Somincor (Sociedade Mineira de Neves-Corvo SA, Portugal) showed interest in testing metals recovery from copper concentrates and evaluation of technical and economical feasibility of using biological processes for that purpose. Recently, Somincor has a zinc concentrator and is responsible by the production of a zinc concentrate by treating a sulphide ore with 3.5% Zn and a considerable lead grade. During this process is produced a lead concentrate with high grade of secondary elements (average composition 30% Pb, 8% Zn and 7% Cu), which is a byproduct difficult to commercialize. For Somincor it would be interesting to investigate its possible valorization routes. So, the main objective of this work was to evaluate the bioleaching potential of indigenous microbial consortium (Achada Sludge – AS) from S. Domingos abandoned mine, for metals recovery of two different mineral concentrates: a rich copper concentrate (chalcopyrite) and a lead concentrate (Pb-concentrate).

2 Materials and Methods

2.1 Mineral concentrates

Somincor (Sociedade Mineira de Neves-Corvo SA, Portugal) has being producing for many years a rich copper concentrate as the major product of its operation. This concentrate contains about 25% Cu, 31% Fe, 1.3% Zn, 0.4% Sn and 0.3% Pb. Phase analysis by X-ray diffraction showed the presence of chalcopyrite ($CuFeS_2$) (71%) and pyrite (FeS_2) (20%) as main mineralogical species.

Recently, Somincor started a new zinc plant where a lead concentrate contaminated with zinc and copper (Pb-concentrate) is produced as by-product. This concentrate was essentially composed of lead, zinc, iron and copper sulphides. Its chemical analysis showed: 27% Pb, 8% Zn, 19% Fe, 7% Cu, 29% S, 0.5% As and 0.13%Sb. X-ray diffraction analysis of the concentrate showed galena (PbS) as the major component (32%), followed by pyrite (FeS_2) (28%), chalcopyrite ($CuFeS_2$) (28%) and sphalerite (ZnS) (12%).

2.2 Microbial inoculum

A microbial inoculum, Achada Sludge (AS), was collected at the abandoned cupric pyrite mine (S. Domingos Mine, Southeast Alentejo, Portugal) and was used in the bioleaching tests. This inoculum was enriched and maintained routinely in ferrous sulphate liquid medium (Johnson, 1995).

2.3 Bioleaching assays

The bioleaching assays were carried out in 500 ml Erlenmeyer flasks containing 200 ml of autotrophic basal medium (Johnson, 1995), using 0.5 to 4% (w/v) of metal concentrates (Pb-concentrate or chalcopyrite) as substrate, and 10% (w/v) of inoculum. The initial pH was adjusted to 1.8-2.0, using H_2SO_4 10 N, and then the flasks were kept at 30ºC or 35ºC, under stirring in a thermostated rotary shaker at 150 rpm.

These batch assays were monitored by measuring soluble metal content concentrations (Fe, Zn, Cu) and pH during time (daily/weekly). Simultaneously, blank tests were also carried out in the same operating conditions but without inoculum, and monitored.

2.4 Genetic characterization of microbial population

The AS inoculum is being genetically characterized, in the time course of the leaching process, to identify the microbial community responsible for the bioleaching of the two different metal concentrates (Pb-concentrate or Chalcopyrite). The separation of whole DNA from samples of different bioleaching stages was performed using UltraClean soil DNA isolation Kit (MO BIO). After isolation of gDNA, PCR was done using 16S rDNA primers for bacteria and archaea, primers 1510R and 1492R respectively, (Hugenholtz and Goebel, 2001). The amplicons were inserted in pJET plasmid (CloneJET PCR cloning kit, Fermentas) and a metagenomic library was constructed with recombinant DH5α cells with clones with

partial 16S rDNA gene that were sequenced by an ABI PRISM 310 sequencer (Applied Biosystems). In order to assess the effect of combined contamination of heavy metals on bacterial communities a genetic community fingerprinting by 16S rDNA profiles is being performed.

The sequencing data was analyzed as follows: (i) assembly of the reverse and forward sequences into a consensus sequence, (ii) editing of the consensus sequence to resolve discrepancies between the two strands by evaluation of the electropherograms, and (iii) comparison of the consensus sequences with GenBank sequences by using Ribosomal Database Project (RDP-II; Michigan State University, East Lansing) (Maidak et al., 2001) and the basic local alignment search tool (BLAST) (Benson et al., 2002).

3 Results and Discussion

3.1 Bioleaching results

In this study a inoculum (AS) from S Domingos mine was tested for its ability to bioleach two sulfide concentrates: a copper concentrate (chalcopyrite) and a Pb-concentrate.

The results obtained in the screening batch assays for chalcopyrite bioleaching with 1% pulp density at two different temperatures, 30ºC and 35ºC, are presented in Fig. 1. An augment of 5ºC in the incubation temperature (30ºC to 35ºC) led to a significant increase in the % metals recovery: ΔFe - 45% (39.3 to 57.0%), ΔCu – 76.6% (26.9 to 47.5%) and ΔZn – 29.4% (48.6 to 62.5%).

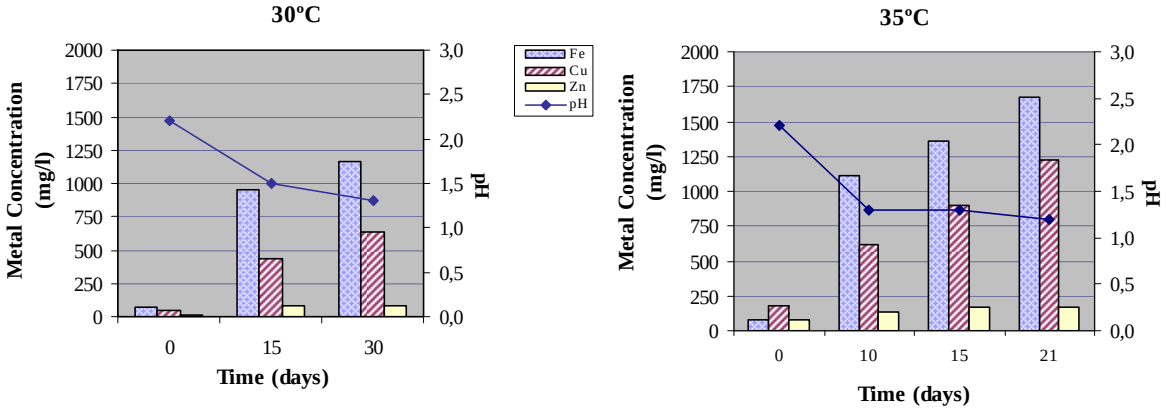

Fig. 1. Bioleaching results obtained in chalcopyrite (1%) for AS inoculum at 30ºC and 35ºC.

Based in these results, the effect of pulp density concentration (1, 2 and 4% chalcopyrite) was evaluated at 35ºC and the percentages of metal recovery by AS inoculum are presented in Table 1. Data showed that the highest % metals recovery: Fe – 92%, Cu – 92.5% and Zn – 100% was obtained at 1% chalcopyrite after 1 month of incubation time. Blank tests showed a % of metal recovery ranged from 5.9% (Fe) to 27.7% (Cu).

It was clear that the increase of the chalcopyrite concentration from 1% to 4% (w/v) resulted in decreased numbers of metals recoveries: Fe - 92.0 (1% Chalc.) to 61.8% (4%

Table 1. Percentage of metals recovery by AS inoculum in bioleaching batch assays with different concentrations of chalcopyrite (1 to 4%).

Sample	Bioleaching Time (days)	% Metals Recovery		
		Fe	Cu	Zn
AS + 1% Chalcopyr.	7	9.8	18.5	24.9
	15	80.4	25.7	52.1
	30	**92.0**	**92.5**	**100**
AS + 2% Chalcopyr.	7	17.7	11.8	42.0
	15	41.0	29.6	75.0
	30	**77.3**	**76.3**	**91.7**
AS + 4% Chalcopyr.	7	8.8	11.0	31.4
	15	34.4	17.7	33.9
	30	**61.8**	**43.1**	**50.9**

Chalc.), Cu – 92.5 (1% Chalc.) to 43.1% (4% Chalc.) and Zn – 100.0 (1% Chalc.) to 50.9% (4% Chalc).

This decrease in AS bioleaching potential suggests the need of a previous enrichment technique with sucessive increasing of substrate concentration to improve inoculum aclimatization to chalcopyrite and selected metals leading an optimi-zation of the bioleaching process.

Relatively to the AS ability to bioleach Pb-concentrate the results obtained in a first screening assay, carried out during 2 months with concentrations of 0.5-2.0% Pb-concentrate, showed that AS was able to recover 65% Fe, 82% Cu and 100% Zn for 2% concentrate (Table 2). In blank assays the % of metal recovery ranged from 0% (Cu, Fe) to 10% (Zn).

Table 2. Percentage of metals recovery by AS inoculum in bioleaching batch assays with different concentrations of Pb-concentrate (0.5 to 2%).

Sample	Bioleaching Time (days)	% Metals Recovery		
		Fe	Cu	Zn
MI + 0.5% Pb Conc.	30	30.4	57.6	100
	45	**31.4**	**78.5**	**100**
	60	23.1	69.7	100
MI + 1% Pb Conc.	30	38.9	59.6	100
	45	40.9	82.1	100
	60	**40.1**	**88.2**	**100**
MI + 2% Pb Conc.	30	50.4	48.9	100
	45	45.7	65.7	100
	60	**65.1**	**82.2**	**100**

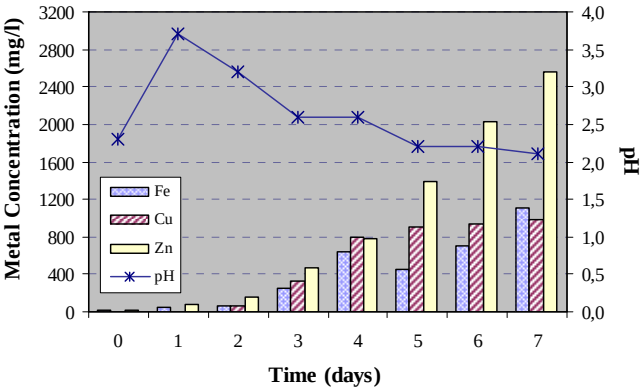

Fig. 2. Metals removal (Fe, Zn, Cu) during bioleaching process by AS, for 4% Pb-concentrate, at pH 1.8-2.0.

In order to verify the previous results, a set of assays with successive increasing pulp density (2 to 4%) was carried out with AS inoculum to evaluate its adaptative potential to higher levels of Pb and to improve its bioleaching potential increasing Zn dissolution.

The results obtained for metal recovery from 4% Pb-concentrate are presented in Fig. 2. The biological activity is confirmed by the pH trend during the leaching process, remaining at low values (pH ≈2.0), and by the increase in the % metals recovery reaching to about 80% of zinc recovery from the Pb-concentrate in 7-days.

During Pb-concentrate bioleaching the adaptative potential of AS microbial population was clearly showed in the successive enrichments with increasing pulp density, with an improvement of zinc removal from 1720 mg/l in 1-month (2% Pb-concentrate) to 2719 mg/l in only 7-days (4% Pb-concentrate).

In conclusion, LA consortium presented an high bioleaching potential for metal-recovery from both mineral concentrates tested. Biometallurgy processes applied for Cu-recovery in copper concentrate (chalcopyrite) and for Zn-recovery in Pb-concentrate can be an interesting tool to improve the added value of products. In the case of Cu concentrate this process would allow the implementation of a copper bio- hydrometallurgy to produce copper cathodes instead of selling a concentrate. For the Pb-concentrate, this type of treatment could improve the economic interest of products, which constitutes a residual stream.

3.2 Genetic characterization of microbial population

A first screening of the indigenous microbial consortium (AS), collected at the abanboned S. Domingos copper mine, using 16S rRNA genes sequencing allowed the identification of the more representative microbial strains present in the original inoculum. A total of 558 clones

were grouped into 5 operational taxonomic units (OTUs). These preliminary results indicates, according to the expected, that in this consortium are present strains like *Leptospirillum ferroxidans*, *Thiobacillus* sp, *Acidithiobacillus ferroxidans*, *Sulfobacillus* sp, *Acidithiobacillus albertensis and Acidithiobacillus thiooxidans*.

Topic: Sustainable process-product development through green chemistry.

Abstract

Phenolic compounds are present in several types of wastewater but with special incidence in the agro-industries effluents. The knowledge of the kinetic parameters is of main importance to design and optimize the reactors where will occur the treatment of these wastewaters. Hence, with this work a competitive method is applied to calculate and compare kinetic constants of the phenolic compounds oxidized by Fenton's reagent process. The phenolic compounds studied were: *p*-coumaric, caffeic, veratric, ferulic, protocatechuic, vanillic, syringic, β-resorcylic, 3-(4-hydroxyphenyl)-propionic and 3,4,5-trimethoxybenzoic acids.

1. Introduction

Pulp and paper industries, wine production, distillery industries, olive-oil extraction and table olive production are examples of industries and agro-industries that produce highly contaminant wastewaters. These wastewaters are characterized for being rich in organic substances (phenols, polyphenols, organic acids), high COD values and a remarkable recalcitrant character due to the presence of phenolic compounds.

As result of this situation and the more restrictive legislation concerning effluents released into rivers and streams, new technologies have been developed to reduce these refractory contaminants. For example, Fenton's reagent oxidation is a homogeneous catalytic oxidation process based on the generation of very reactive oxidising free radicals, especially hydroxyl radicals, through the combination of hydrogen peroxide and ferrous ions. The oxidation mechanism of Fenton's reagent is complex, but could be resumed in the following reaction (Parsons, 2004):

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + HO^- + HO\bullet \qquad (1)$$

Hence, the main objective of this study is to calculate and compare the kinetic constants of the Fenton's reagent oxidation process of phenolic compounds normally present in industrial wastewaters using a competitive kinetic model. The comparison is made with a phenolic compound which constant kinetic is known: the *p*-hydroxybenzoic acid, with a value of is 2.2 x 10^9 $M^{-1}s^{-1}$ (Haag and Yao, 1992). The 10 phenolic

* Corresponding author. Tel + 351-259-350227. E-mail:jperes@utad.pt

compounds studied were: *p*-coumaric, caffeic, veratric, ferulic, protocatechuic, vanillic, syringic, β-resorcylic, 3-(4-hydroxyphenyl)-propionic and 3,4,5-trimethoxybenzoic acids.

2. Materials and methods

Analytical grade phenolic acids (Figure 1) were obtained from Sigma. Hydrogen peroxide (30% w/w) and ferrous sulphate heptahydrate were obtained from Merck.

The reactor consisted in a 1 L glass cylinder provided with the necessary elements (inlets for stirring, sampling and measuring the temperature) for the development of the experiments. This reactor was kept at the desired temperature within ±0.5°C. Initially, the reactor was loaded with 500 mL in all cases, and the initial concentration of each phenolic compound was 100 mg/L.

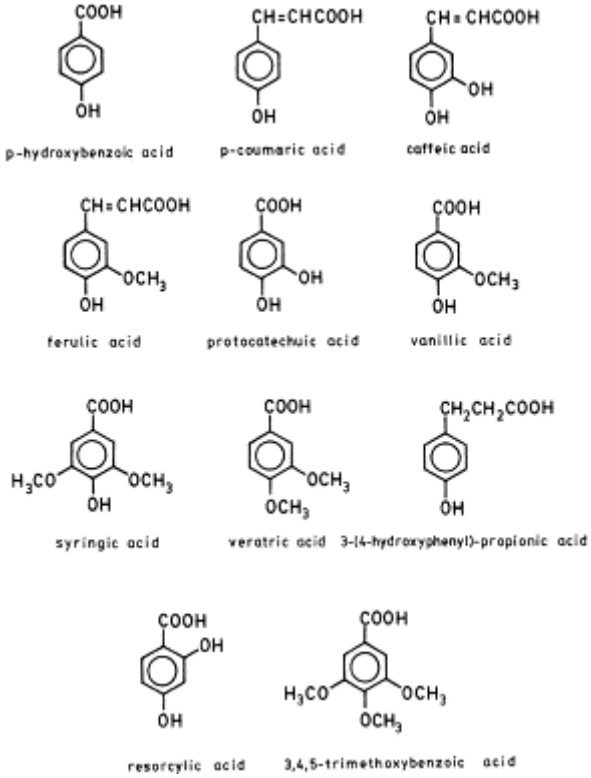

Figure 1 - Phenolic compounds

At regular times of reaction, samples were withdrawn to determine the phenolic acids remaining. These samples were analysed by HPLC, using a Waters chromatograph with a 996 photodiode array detector and a Nova-Pak C18 Column. Detection was at 280 nm with a mobile phase composed of a methanol:water:acetic acid mixture (15:82.5:2.5 in volume) at a flow rate of 1 mL/min.

3. Results and discussion

A series of experiments were developed to determine the rate constants for the reaction between each individual phenolic compound and hydroxyl radicals generated in Fenton process. These determinations were performed under certain specific conditions, by means of a competitive kinetic model. In this case, was used a mixture of a reference compound (R), *p*-hydroxybenzoic acid, and another phenolic compound (B).

In all the decomposition experiments of phenolic compounds by Fenton's reagent a progressive decrease of the different compounds is appreciated with reaction time. As an example Figure 2 shows the disappearance curves of some phenolic compounds: β-resorcylic acid, 3-(4-hydroxyphenyl)-propionic acid, ferulic acid and the reference compound p-hydroxybenzoic acid.

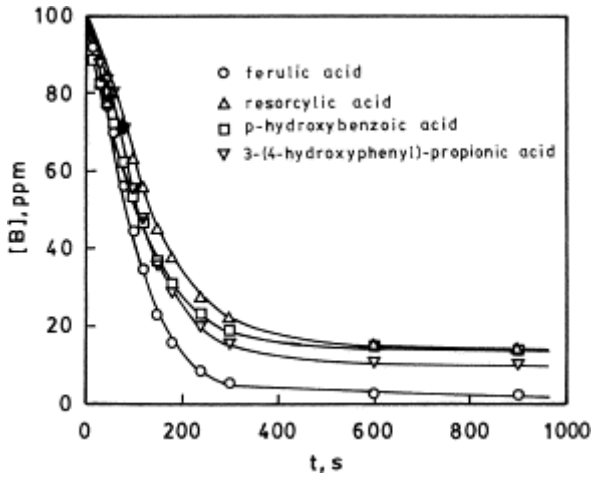

Figure 2 – Evolution of the concentration of phenolic compounds along the oxidation experiments: ferulic, resorcylic, p-hydroxybenzoic and 3-(4-hydroxyphenyl)-propionic acids.

The process of oxidation by ·OH radicals could be carried out in a system containing a mixture of compound B and a reference compound R, whose rate constant is known. The equation of the reaction between each organic B and the ·OH radical can be expressed by the reaction (2):

$$B + {}^{\cdot}OH \rightarrow B_{ox} \qquad (2)$$

Assuming a first-order reaction with respect to the radical concentration and the phenolic acid concentration, the reaction rate can be expressed as:

$$-\frac{d[B]}{dt} = k_B [B][HO\bullet] \qquad (3)$$

where k_B is the rate constant of reaction for every compound B with hydroxyl radical. Similarly to the Eq. (3), the reference compound presents the following rate equation:

$$-\frac{d[R]}{dt} = k_R [HO\bullet][R] \qquad (4)$$

By dividing both (3) and (4) it is obtained:

$$\frac{d[B]}{d[R]} = \frac{k_B}{k_R}\frac{[B]}{[R]} \qquad (5)$$

and integrating between t=0 and t=t:

$$\ln\frac{[B]_0}{[B]} = \frac{k_B}{k_R}\ln\frac{[R]_0}{[R]} \qquad (6)$$

In this expression k_R is the rate constant for the reference compound, i.e., p-hydroxybenzoic acid with $k_R = 2.2 \times 10^9$ L/(mol.s) at 30 ºC and k_B is the rate constant for each one of the phenolic compounds. A plot of $\ln([B]_0/[B])$ versus $\ln([R]_0/[R])$ yields a straight line, whose slope is the ratio of rate constants k_B/k_R, as showed as an example in Figure 3.

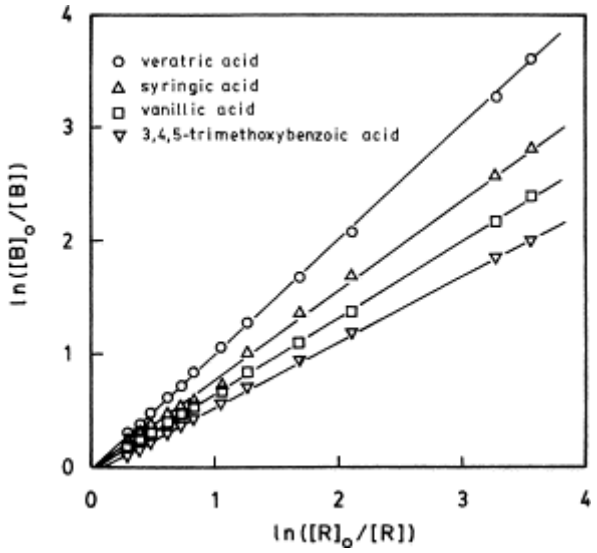

Figure 3 - Plot of $\ln([B]_0/[B])$ versus $\ln([R]_0/[R])$ for some phenolic compounds: veratric, syringic, vanillic and 3,4,5-trimethoxybenzoic acids.

Figure 3 shows this plot as an example of different phenolic compounds: veratric, syringic, vanillic and 3,4,5-trimethoxybenzoic acids. As can be seen, the excellent alignment of the points around straight lines confirms the goodness of the described method. After regression analysis, the slope k_B/k_R for each compound was deduced, and using the known k_R, the rate constants k_B for the remaining phenolic compounds are determined. The values are exposed in Table 1.

Table 1 - k_B/k_R and k_B values for each phenolic compound

Phenolic compound	**k_B/k_R**	**$k_B \times 10^{-9}$** (L/mol.s)
Ferulic acid	1.754	3.8
3-(4-hydroxyphenyl)-Propionic acid	1.172	2.6
p-Coumaric acid	1.155	2.5
Veratric acid	1.011	2.2
***p*-Hydroxybenzoic acid** (reference)	**1.000**	**2.2**
β-Resorcylic acid	0.991	2.2
Caffeic acid	0.821	1.8
Syringic acid	0.791	1.7
Vanillic acid	0.672	1.5
3,4,5-Trimethoxybenzoic acid	0.567	1.2
Protocatechuic acid	0.307	0.7

It is possible to deduce that cinnamic acids, with 9 atoms of carbon (C_6-C_3) like ferulic, veratric and caffeic acids have, in general, kinetic constants higher than the benzoic acids with 7 carbon atoms (C_6-C_1).

These values are concordant with the deduced values for hydroxyl radical rate constants in aqueous solution for other similar compounds in an order of 10^9 L/(mol.s) (Abad *et al.*, 2007) and moving closer to the limit the reaction controlled by diffusion.

Note that in the case of extremely fast reactions, with reaction times very short, such as the reactions of phenolic acids with hydroxyl radical, it is sometimes difficult to distinguish between "physical" and "chemical" changes. Bimolecular reactions, like in this case, consist of at least two steps: the approach of the two species, controlled by diffusion and real chemical transformation. Second-order (or pseudo-1st order) constants cannot, therefore, exceed those for the diffusion process. This limits the maximum attainable to around 10^9-10^{11} $M^{-1}s^{-1}$.

Comparing kinetic reaction of the different phenolic compounds with the Fenton's reagent shows that variations between the compounds studied are small, which may suggest, in a first analysis, that substitute groups have a small effect on the attack to benzenic ring by Fenton's reagent. Indeed, the hydroxyl radical, which is the basis of Advanced Oxidation Processes, is very reactive, but not very selective.

In the case of attacks by free radicals there should be no major differences regarding reactivity of aromatic compounds having electrons acceptors or electrons donors groups. However, it is generally accepted that high density electronics in the ring tends to inhibit the oxidation by free radicals.

For example, the reactivity of monosubstitutes phenols by a nitro group or by a halogen atom (both electrons acceptors) is similar to that of phenol (Vella, 1992). The unstabilizing effect becomes more important with multissubstitution, as it happens with the acid 3,4,5-trimetoxibenzoic acid.

For Lipczynska-Kochany (1991), the influence of substitute groups in the reactivity of $HO^{\cdot}$ radical with aromatic compounds, showed that the $HO^{\cdot}$ mechanisms' attack to an aromatic compound is similar to the reaction of electrophilic substitution. For example, the presence of donor groups of electrons, as the groups –OH or -OCH_3 in aromatic ring, is known to activate the ring in reactions of electrophilic substitution (Table 2).

Table 2 – Effect of substituints on electrophilic aromatic substitution (Solomons and Fryhle, 2000).

Functional group	Group characteristics	Director
-OH	Strongly activating	Ortho-para
-COOH	Moderately deactivating	Meta
-CH=CHCOOH	Weakly activating	Ortho-para
-OCH_3	Moderately activating	Ortho-para
-CH_2COOH	Weakly activating	Ortho-para

There are small differences in reactivity between the phenolic compounds, although, sometimes, there are not very significant structural differences between them. This means that the presence of certain substituents groups (hydroxy, di-hydroxy, methoxy) in specific positions of the aromatic ring influence the efficiency of the reaction. In general, the electrophilic substitution reactions are delayed by the presence of acceptors groups of electrons and promoted by donors groups of electrons.

4. Conclusions

The application of a competitive method allows to calculate the rate constant for 10 phenolic compounds based on the rate constant previously known of the reference compound *p*-hydroxybenzoic acid. The phenolic compounds studied were: *p*-coumaric, caffeic, veratric, ferulic, protocatechuic, vanillic, syringic, β-resorcylic, 3-(4-hydroxyphenyl)-propionic and 3,4,5-trimethoxybenzoic acids. The deduced values for hydroxyl radical rate constants in aqueous solution for these phenolic compounds are in the range of (0.7 – 3.8) x 10^9 $M^{-1}s^{-1}$.

Abstract

The research work presented in this paper considers polymerization process in MITOL, a chemical factory in Sezana, Slovenia. The challenge is to increase the production rate while keeping the quality parameters at the desired values. A possible approach to reach that goal is by applying better control strategies that will decrease the batch time. For this purpose a model consisting of differential and algebraic equations (DAE) has been already constructed and is extended in this paper with the energy balance model to simulate the reactor temperature as a function of reacting chemicals. The model will be used for control design and in the search for more optimal plant operation. Model simulation results based on real plant data, derived in gPROMS environment, are presented.

1 Introduction

Emulsion polymerization of vinyl acetate is an important process in the chemical industry. Efforts have been made to determine the mechanism of the reaction. A good number of comprehensive models of vinyl acetate with different theories and approaches could be found in the literature. In 1992, Urquiola et al.[1][2][3] wrote a series of papers about the polymerization of vinyl acetate using a polymerization surfactant.

The research work presented in this paper considers the polymerization process in MITOL factory, Sezana, Slovenia. This is the leading glue manufacturer in the country with production rate more than 90% of its capacity. The production process is semi-batch polymerization with initiator and monomer added during the batch. The current batch control is done by following a recipe derived from experience. Monomer is added at a constant flow, while initiator addition is performed manually and is used to control the temperature in the reactor. The challenge we are facing now is to design optimal control actions required to reach the final product with specified quality parameters in as short time as possible. The large quantities of raw materials and equipment resources involved in the batch prevent us from performing experiments for batch optimisation directly on the plant. Therefore we need a good predictive model for controlling the temperature and also the addition of the initiator and monomer. The already constructed model [4] provides estimates of four outputs: conversion, solid content, viscosity and particle size diameter. In this paper we extend the model using first principle modelling based on energy balance to observe the reactor temperature as a function of the concentration of reacting chemicals. Having temperature we are able to design and test control strategies for shortening the batch duration with initiator and monomer addition as control variables.

2 Process description

The process presented hereby is a polymerization of vinyl acetate by using potassium persulfate (KPS) as initiator and polyvinyl alcohol as a protective colloid. The production process is semi-batch polymerization. In the beginning initial amounts of initiator and monomer as added in the reactor as well as the whole amount of water and polyvinyl alcohol (PVOH). The reactor is closed and the heating starts. When the temperature of the reactor reaches approximately 70˚C, the operator stops the hot water through the heating jacket (Figure 1). The exothermic reaction and the heat of the remaining water filling the heating coat continue to rise the temperature. After the reactor temperature reaches a certain level, the remaining fixed amount of monomer starts to be pumped into the reactor with a constant flow. The monomer flow rate is controlled by a PID controller acting on the pump. The temperature of the added monomer is the outdoors temperature.

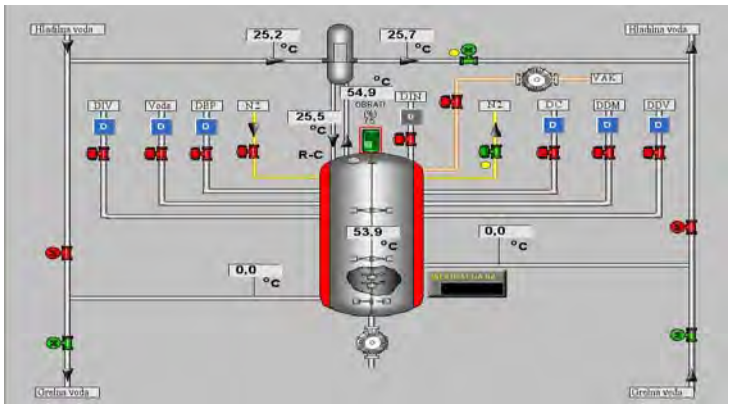

Figure 1. *Scheme of polymerization reactor in MITOL*

For emulsion polymerization processes it is very important to keep the temperature in certain limits. For vinyl acetate those limits are 75-80°C. Therefore every time the temperature starts to decrease a determinate amount of initiator is added in the system so that the temperature starts increasing. When all the monomer is added into the reactor a larger amount of initiator is added in order to terminate the reaction. The temperature is then allowed to increase up to 90°C. The reaction is considered as finished when the temperature starts to decrease again.

The main variables affecting the duration of the reaction and possibly used in batch optimization are: the reactor temperature, flow rate of the monomer and the addition of the initiator.

The quality of the product is defined by the following parameters: conversion into polymer, particle size distribution, viscosity and solid content.

3 The Model

The current model is based on a model described in previous papers [4][5]. For control purposes we estimate the temperature profile from an energy balance model. The energy balance model is based on reaction heat capacity and the energy produced and consumed during the reaction. The latter include the following:

- Heating of the reactor through the heating jacket,
- Producing the heat in the exothermic reaction,
- Heating the incoming monomer to the reactor temperature,
- Cooling the reactor by the reflux,
- Heat losses to the surroundings.

Reaction heat capacity (K_R) accounts for the heat capacities of the reactor ingredients - monomer, converted into polymer monomer, water and polyvinyl alcohol. It also depends of their mass and specific heat capacities. It is given by the equation:

$$K_R = M\ MW_m\ Cp_{mon} + M_{conv}\ MW_m\ Cp_{pol} + W\ Cp_{water} + PVOH\ Cp_{pol} \quad (1)$$

The energy balance model is divided into three parts, depending of the stage of the process and the reaction. The first part of the modelled temperature profile starts when we close the reactor and start heating it up with hot water through the heating jacket, and ends when we stop the hot water and wait till the temperature in the reactor reaches around 80°C. In that first part we take into account the monomer enthalpy, the heating produced due to the exothermic reactions and heating though the heating jacket. This is mathematically expressed as follows:

$$K_R \frac{dT_R}{dt} + T_R \frac{dK_R}{dt} = Q_m MW_m Cp_{mon} T_{mon} - \Delta H_r r_{pol} - C_3 \Delta H_{jacket} \quad (2)$$

The left side of the equation accounts for the changes in the internal energy of the reactor, which is due to the change of the reactor temperature (first term) and the change of its heat capacity (second term). The heating through the heating jacket (ΔH_{jacket}) is given by:

$$\Delta H_{jacket} = 0.00018(T - T_{jacket})K_R \quad (3)$$

The second part of the model starts at the end of the first part and ends at the first initiator addition during the batch. In that part the reactor is no more heated through the heating jacket, the losses are negligible, as well as the flow through the condenser because the reaction has just been started. The energy balance model includes only monomer enthalpy and the reaction heat:

$$K_R \frac{dT_R}{dt} + T_R \frac{dK_R}{dt} = Q_m MW_m Cp_{mon} T_{mon} - C_4 \Delta H_r r_{pol} \quad (4)$$

The energy balance for the third last part of the modelled temperature profile takes into account also the reflux through the condenser and heat losses. The equation has the following form:

$$K_R \frac{dT_R}{dt} + T_R \frac{dK_R}{dt} = Q_m MW_m Cp_{mon} T_{mon} - C_5 \Delta H_r r_{pol} - Q_{cond} - C_6 Q_{loss} \quad (5)$$

Here the energy loss through the condenser (Q_{cond}) is calculated by the following equation:

$$Q_{cond} = Q_{FC} Cp_{Cout} (T_{Cout} - T_{Cin}) - Q_{FC} \lambda \quad (6)$$

where λ is the vaporization heat and it is:

$$\lambda = -0.00281 T_{Cout}^2 - 0.32738 T_{Cout} + 408.178 \quad (7)$$

Losses through the surroundings are given by:

$$Q_{loss} = 0.95(T - T_{ext}) \quad (8)$$

Model parameters in the equations (1-8) are taken from the literature [6] (MW_m, Cp_{pol}, Cp_{mon}, Cp_{out}, ΔH_r) or estimated based on real plant data (C_3, C_4, C_5, C_6) so that a satisfactory agreement between the process and the model was obtained. The values of model parameters are given in Table I.

Parameter	*Value*
MW_m [gmol^{-1}]	86.09
Cp_{pol} [kJ kg^{-1} K^{-1}]	1.77x10^{-2}
Cp_{mon} [kJ kg^{-1} K^{-1}]	1.77x10^{-2}
Cp_{out} [kJ kg K^{-1}]	1.17
Cp_{water} [kJ kg K^{-1}]	4.18x10^{-2}
T_{ext} [K]	283.15
ΔH_r [kJ mol^{-1}]	-87.5
C_3 (dimensionless)	0.50
C_4 (dimensionless)	0.35
C_5 (dimensionless)	0.60
C_6 (dimensionless)	Depending on the batch

5 Results

The presented model was simulated using gPROMS modeling tool [7][8]. Model simulations were performed based on real plant data. The flow rates of the added monomer and initiator during the batch were calculated from the weight change of the monomer and initiator dozing tanks. Examples of reactor temperature, initiator and monomer flow rates during the batch are shown in Figure 3.

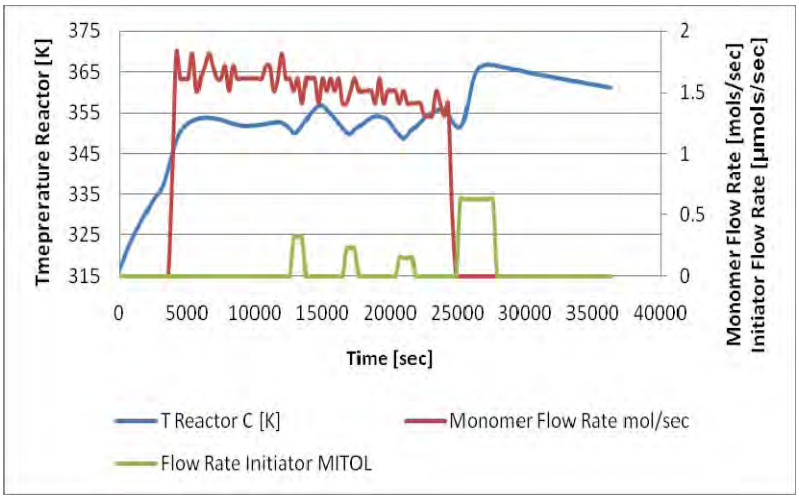

Figure 3. *Initiator addition, monomer flow rate and temperature profile during the batch*

With the presented energy balance model we are able to get relatively good estimates of the reactor temperature. From Figure 4 it can be seen that the estimated profile follows the dynamics of the real one. Not so good estimates are obtained at the beginning and at the end of the batch. At the beginning of the batch, the most influential part of the model is the heating of the reactor through the heating jacket. So most probably, the corresponding model parameters still need to be estimated more precisely. The agreement of the model is also not good in the last part of the estimated profile. This is when the whole amount of monomer has been already added in the reactor and a larger amount of initiator is put to finish the reaction. A possible reason is that in this part the actual heat losses are higher than estimated.

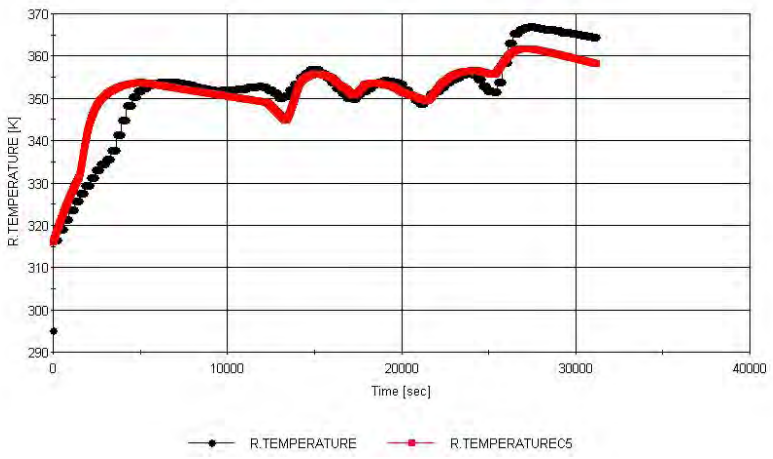

Figure 4. *Estimated and real plant temperature profile*

The overall model was also used to calculate the product quality parameters. Table II shows the validation of model on 5 batches. For the viscosity and the solids content, laboratory analyses were performed at the end of the reaction. These measurements are normally performed after mixing several batches and therefore no individual data is available.

Table II *Output variables – real plant data and estimated data*

Batch No.	Conversion (%)		Solids Content (%)		Viscosity (Brookfield 200C, 50rpm), (mPas)	
	Real Data	Modelled Data	Real Data	Modelled Data	Real Data	Modelled data
1192	99.95	99.79	46.4	45.84	37520	33723
1203	99.90	99.74	45.9	45.86	31200	36324
1214	99.89	96.17	45.4	43.88	25040	32697
1253	99.13	99.36	46.9	45.97	34000	35486
1256	99.37	99.45	46.4	45.61	30160	33343

From the table we can see that the model output variables are in good agreement with real plant data. To obtain these results it was necessary to adjust the C_6 parameter for each batch. This could be attributed to the variable and increased fouling of the reactor walls between cleaning periods. The average model error for conversion and solids content is around 2% and for the viscosity around 15%. Some bigger deviations can be noticed for batch 1214 for all output variables.

6 Conclusion

A model for polymerization of vinyl acetate has been developed. The model has two inputs – flow rate of monomer and flow rate of initiator addition. The outputs of the presented model are four – conversion, particle size diameter, solid content and viscosity. The overall model has thirteen differential equations, sixty-three algebraic equations and nine adjustable parameters. In this model we are able to observe temperature profile and based on it apply the control of the initiator addition and estimate more precisely the sufficient amount of initiator which needs to be added during the batch. The model has been validated on data of five batches taken from the real plant. The presented temperature profile is quite satisfactory and also the model output variables are in the range. The work continues with the design and testing of initiator and monomer control strategies.

At present, mathematical modeling is successfully used to support decision making in the development and modernization of chemical processes and reactors. Note that modernization of chemical processes and reactors is the interdisciplinary problem, which requires the involvement of experts in physics, chemistry and mathematical modeling. Determination of kinetic scheme of chemical reactions is a key stage in devising a mathematical model of reactor. Such a scheme includes the proposed reaction mechanism and the values of rate constants for individual reaction steps. It was shown elsewhere that different kinetic schemes used to describe a certain reactive flow with the same gas-dynamic parameters lead to radically different simulation results. In the literature, a process can be described by alternative schemes due to the prevalence of semiempirical models of chemical kinetics, with stoichiometric equations being used instead of elementary steps. Although semiempirical representations are of limited use, the development of such kinetic schemes is quite topical, as they provide a model of reactive medium, which is adequate in a specified range of conditions. The development of semiempirical models and determination of rate constants for individual reaction steps are based on the full-scale and computational experiments. The computational experiment aimed at determination of kinetic scheme is the iterative process including the following stages: advancement of a postulated reaction scheme; generation and solution of a stiff nonlinear set of ordinary differential equations that describes chemical transformations of substances within the proposed scheme; and comparison of numerical and experimental data on the reaction kinetics.

Note that a correct comparison of the calculated and experimental data is not a trivial task, since each time it is necessary to evaluate the roughness of numerical model and the accuracy of measurements. Thus, to determine the parameters of elementary steps in relatively simple kinetic schemes, it is reasonable to use a detailed two-dimensional model taking into account the diffusion, heat conduction and heterogeneous reactions on the reactor walls in combination with the in situ spectral diagnostics. The development of semiempirical schemes for more complicated processes (e.g., pyrolysis of hydrocarbons) permits the use of more rough models due to technical limitations of experimental diagnostics. Analysis and selection of kinetic schemes can be performed with any software package that solves the primal problem of chemical kinetics, i.e., determines changes in the composition of reacting mixture that occur with time. However, most of them are not intended for the search of kinetic schemes. Besides, in many cases, the proposed scheme can be evaluated only in the context of its energy effects or design features of the reactor where the experiments are carried out. Such analysis should be based on spatial models of the reactive medium. Thus, program packages intended for research and engineering work (HYSYS, ReactOp, CARAT, etc.) were suggested for reactor optimization and kinetic model development. Employing the library of reactor models, a user can make computations with these models using different kinetic schemes entered via the package interface. For instance, the ReactOp library comprises 30 types of single reactors with liquid and gaseous reactants, and seven types of cascade reactors. FORTRAN codes implementing the numerical models of these reactors are extensible, which allows a user to modify them. This approach is convenient when working with the most-used reactor designs, since all the stages of chemical process simulation and optimization can be performed within a

single software product. However, this approach has some limitations: the development of mathematical models for new type reactors will require a considerable extension of each library; and the search problem using a full model of reactor will be highly time-consuming. When searching for an adequate kinetic scheme, the most simple (one-dimensional) reactor models will be used, and simulation will be performed for a wide range of temperatures and pressures. Then the chosen kinetic scheme can be included in computations by the three-dimensional models implemented in commercial or special-purpose CFD packages. The modeling results can be obtained quite rapidly due to a rational use of computational tools at the stage of kinetic scheme development and through an orderly division of labor of the specialists involved in the simulation process and computations.

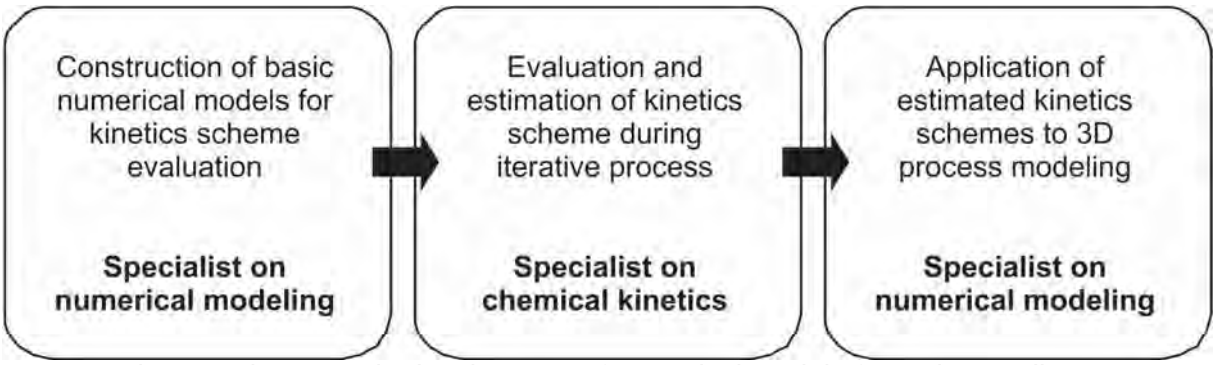

Fig. 1. Main stages in development of numerical model of reactive medium.

Figure 1 shows three main stages necessary for the development of numerical model of reactive medium. At the first stage, basic numerical models of reactive medium are constructed and codes for evaluation of kinetic schemes are chosen. This work can be operated by the specialists in mathematical modeling and chemical kinetics. The second stage consists in evaluation and estimation of the kinetic scheme during the iterative process. This work can be operated by the specialists in chemical kinetics using the efficient chemical kinetics software. At the third stage, the estimated kinetic schemes are applied to three-dimensional simulation of the reactive medium (CFD + chemical reactions, etc.). This work can be operated by the specialists in mathematical modeling. For the first two stages, a new software package ChemPAK was developed by the authors. ChemPAK can be operated by a specialist in chemical kinetics without any knowledge on mathematical modeling. ChemPAK can work with the systems of chemical reactions stored in the network database or obtained via the package interface. Then the program automatically generates a numerical model of the chemical reaction system and makes the computations. Thus, a user of ChemPAK can obtain the results of numerical modeling, adjust the chemical kinetic scheme, and promptly evaluate the resulting scheme.

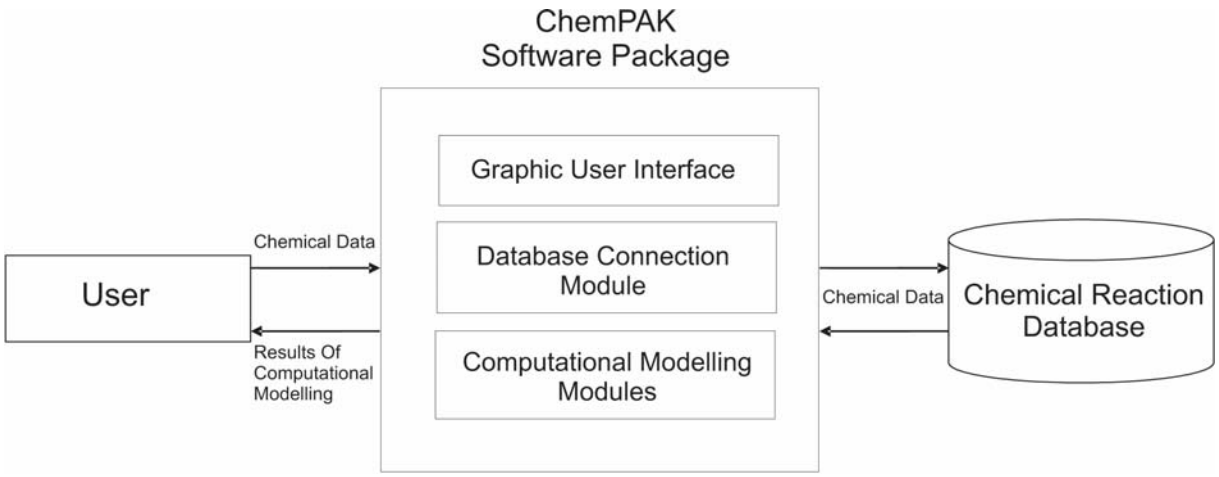

Fig. 2. The architecture of ChemPAK.

Figure 2 shows architecture of ChemPAK software package. ChemPAK consists of network database, computational modules and visual interface. User can create and edit systems of chemical equations with unlimited number of equations with easy-to-use interface, translate systems of chemical equations to systems of ODE, add some new equations to the translated system and solve this system by using one of ChemPAK computational modules. ChemPAK can work with the systems of chemical reactions stored in the network database or obtained via the package interface. Then the program automatically generates a numerical model of the chemical reaction system and makes the computations. Thus, a user of ChemPAK can obtain the results of numerical modeling, adjust the chemical kinetic scheme, and promptly evaluate the resulting scheme.

ChemPAK was tested on different tests. Main tests are the problem of modeling kinetics of Butlerov reaction in circumstellar disk and the problem of homogenous pyrolysis of C2-C3 hydrocarbons under CO2-laser-induced heating. The problem of modeling kinetics of Butlerov reaction consists of 44 reversible chemical equations. Reaction scheme for homogenous pyrolysis of C2-C3 hydrocarbons consists of more than 100 chemical equations. These problems are fully described in referenced works.

Keywords: Multiobjective Optimization, Goal Attainment Method, Benzene Nitration
Topic: Systematic methods and tools for managing the complexity

Abstract

The nitration of benzene with mixed acid is an important chemical process where liquid-liquid reactions take place, whose degree of conversion to mononitrobenzene (MNB) and selectivity depend on a wide range of parameters. Santos (2005), studied this system in a pilot plant under operating conditions in the range of those used in the industrial process. The experimental data thus collected are here used in order to set up a strategy for establishing an adequate trade-off between two conflicting objectives: to maximize the MNB concentration while minimizing by-products (di- and trinitrophenol – DNP and TNP) formation. The methodology consisted in searching for the optimum noninferior solutions, by establishing a multiobjective optimization problem (MOOP) bound to be solved by the Goal Attainment Method (GAM). A statistical multivariate analysis approach was adopted to develop empirical models for estimating the DNP and TNP concentrations, and the predictions are in good agreement with the experimental data. The definition of the feasible region for the optimum search had in consideration the intrinsic relationships in the operating conditions found in data. A Pareto front in the feasible region was identified, showing that a reduction in by-products concentration can only be achieved for lower MNB concentrations. The multiobjective optimization results obtained are expected to assist process engineers in the selection of the operating conditions according to theirs production targets.

1 Introduction

In the continuous adiabatic benzene nitration process to produce MNB, the DNP and TNP are by-products that have to be removed from the final product. As they represent a serious menace to the aquatic ecosystems their disposal must follow strict criteria. Aware of this in Santos (2005) an important contribution was given to understand this system and how operating conditions influence yield and the extent of secondary reactions. The present work aims at using the same experimental data to develop an optimization framework in order to properly rationalize and quantify trade-offs between two conflicting objectives: to maximize the concentration of MNB while minimizing by-products formation, thus reducing the environmental footprint of the process.

If a MOOP is well formed, there should not be a single solution that simultaneously minimizes each objective to its fullest (Censor, 1977). In each case, we are looking for a solution for which each objective has been optimized to the extend that, if we try to optimize it any further, then the other objective(s) will suffer as a result. Finding such a solution, and quantifying how much better this solution is compared to the others, is the goal to be attained in MOOP. Pareto solutions (or noninferior solutions) are then, those for which improvement in one objective can only occur with the worsening of at least another objective. A design

* Corresponding author. Tel + 351-239-798793. E-mail:pagp3@eq.uc.pt

point x* in the objective space, X, is termed Pareto optimal if there is not any another feasible design objective vector, x, such that $x_i \le x_i^*$ for all $i \in \{1,2,...,n\}$, and $x_j \le x_j^*$ for at least one index of $j \in \{1,2,...,n\}$.

In order to find the Pareto front, a scalar method was used, the goal attainment method (GAM) developed by Gembicki (1974, 1975). GAM is a highly effective method for obtaining the best balanced solution to multiobjective problems and, unlike the basic weighted sum of objective functions method, it is not subject to convexity limitations of any kind (Collette and Siarry, 2003). A vector of goals, $g = [g_1,...g_n]^T$, to be attained by a set of objectives, $F(x) = \{f_1(x),...,f_n(x)\}$, is specified in GAM. The relative degree of under or overattainment of the desired goals is controlled by a vector of weights, $w = [w_1,...w_n]^T$, that defines the direction for search from g (*Figure 1*) to the feasible objective space, $\Lambda(\phi)$. The best compromise solution is found by solving the following problem:

$$\begin{aligned} &\text{Min} \quad \phi \\ &\text{S. t.} \quad F(x) - \phi w \le g, \\ &\qquad x \in X, \quad w \in \Re^n \end{aligned} \tag{1}$$

where ϕ is an unrestricted scalar variable, called degree of under, or overattainment of the goals, and X represents a feasible solution region. The term ϕw introduces a degree of slackness into the problem, which would otherwise impose the goals to be rigidly met. The weight vector w enables the decision maker (DM) to express quantitatively the tradeoffs between the objectives. The smaller $|w_i|$, the less the function value of the i^{th} objective, and to make an objective function greater than the corresponding goal value, w_i must be set to be positive.

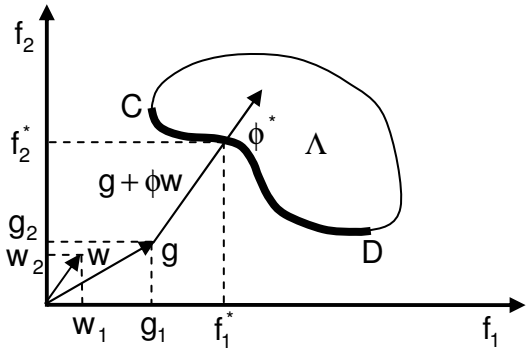

Figure 1 –Graphic representation of the Goal Attainment Method with two objectives.

Given the vectors g and w, the direction of the vector $g + \phi w$ can be determined. Therefore, the problem in (1) is equivalent to finding a feasible solution which is nearest g, but that falls in the line spanned by this vector. The best noninferior solution for this problem will be the first point, ϕ^*, where $g + \phi w$ intersects the feasible region, Λ, in the objective space. During the optimization, ϕ is varied, changing the size of the feasible region. A negative ϕ implies that the goal of the DM is attainable, and an improved solution will be obtained. Otherwise, $\phi > 0$ and the DM goal is unachievable. The attainment method has the advantage that it can be posed as a nonlinear programming problem, which can be solved by classical optimization approaches, such as the sequential quadratic programming (SQP).

Formulating the correct MOOP requires establishing the feasible solution region X which means developing mathematical models for the relationships that constrain the model input

variables. For these relations, a Mahalanobis distance approach (Chatterjee, 1991) was adoped. The squared Mahalanobis distance, MD, is essentially a covariance weighted distance to the centroid, μ, where the covariance is computed from experimental data.

$$MD^2 = (x-\mu)^T \Sigma^{-1} (x-\mu) \qquad (2)$$

Points with MD less than a given threshold belong to an ellipsoid cluster, whose axis ratio depends on the covariance matrix (*Figure 2*). So, unlike an absolute distance measurement, it takes into account the shape of the cluster. For instance, although points A and B appear to be equidistant from the center, in terms of MD, A is much closer, and therefore more likely to be a member of the cluster.

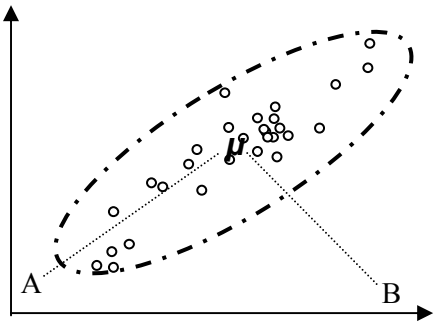

Figure 2 – Geometric interpretation of the Mahalanobis distance.

The threshold is set with resource to the Hotelling's T^2 statistic, which describes the variability of the MD for a multivariate normal distribution, where F stands for the F-distribution for a defined confidence level, α, usually 0,05.

$$T^2 \sim \frac{p(n-1)}{(n-p)} F_\alpha (p, n-p) \qquad (3)$$

This multiobjective optimization approach was used for establishing quantitatively the trade-offs, and the optimum process variables set points that will allow to relate the production of MNB and the concentration of both DNP and TNP, providing essential information for the DM in setting the operating conditions for the benzene nitration process.

2 Problem formulation and results

The reaction mechanisms involved in the production of nitrophenols are complex, and the physical and chemical data required for the development of mechanistic models are scarce. Therefore, a statistical multivariate analysis approach was adopted to develop data-driven empirical models to predict the formation of these compounds. The models in Quadros (2005) were improved, using the same experimental data sets and the multivariate linear regression (MLR) methodology (Chatterjee, 1991) with the forward stepwise variable selection method, implemented in the Statistica® software. The procedure followed is mainly the one described in Quadros, 2005.

The variables chosen as potential regressors were: T, F_B/F_N, NA, SA, *a* and θ. The regressors selection was driven by the aim of developing models that remain valid over a wide range of conditions and hopefully not dependent on the reactor size. Two of the

variables, *a* and T, are not process inputs and can not be set independently from the others. Nevertheless, it is known (Santos, 2005) that *a* is related to the ratio of organic to acid phases, here represented by F_B/F_N, and to the physical properties of the liquid-liquid mixture, which, in turn, are both sensitive to T. By checking the matrix of scatter plots, a relationship between *a*, F_B/F_N and T was established creating a feaseable elliptic cluster based on the concept of MD. A similar procedure was followed for modelling the relationship between NA and SA, since they are concentrations in the mixed acid, and therefore cannot be set independently. This elliptic cluster is shown in *Figure 3*.

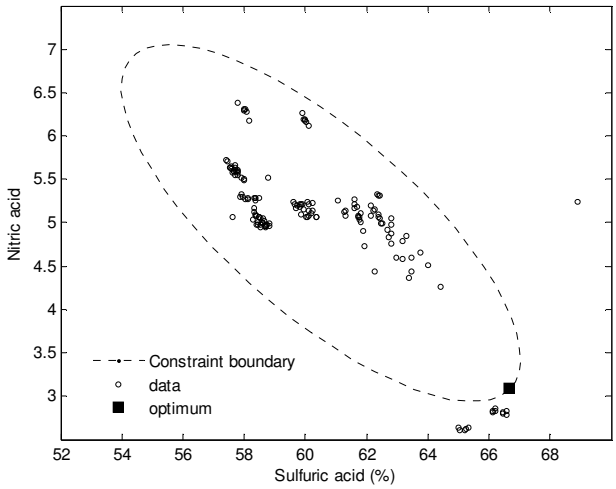

Figure 3 – Data scatter plot relating the concentrations of SA and NA in the mixed acid, showing the constraint cluster and the optimum value.

The problem formulation is then as:

Min ϕ

$x \in \Re^n \quad \phi \in \Re$

$$S.\ t. \quad x_i - w_i\phi \le g_i \quad i = \{1,6,8\} \qquad (4)$$

$$x_i - H(x_j) = 0 \quad i = \{1,6,8\} \quad j = \{2,3,4,5,7\} \qquad (5)$$

$$MD_k^{\,2} = (x_i - \mu_i)^T \Sigma_k^{\,-1} (x_i - \mu_i) \quad k \text{ is the number of the constrain based on the MD} \qquad (6)$$

$$k = 1 \Rightarrow i = \{3,4\}, \quad k = 2 \Rightarrow i = \{2,5,7\}$$

$$lb_i \le x_i \le ub_i \quad i = \{1,\ldots,8\} \qquad (7)$$

Where *(5)* are the set of predictive models for MNB, DNP and TNP, and *(6)* comprehend two restrictions based upon the MD. With the exception of θ, all the upper and lower limit bounds, ub and lb, were relaxed so that they were not active constraints in the optimization process, therefore allowing the constraints *(6)* to freely play their role. Due to the fact that θ is not implicitly limited in constraints *(4)* to *(6),* its upper bound, ub_8, could not be relaxed; as, such upper bound happened to be an active constraint, it must be kept within the range found in collected data (2 to 5 minutes).

Goals were set as $g_i = \{100,0,0\}$, meaning that 100% of MNB and 0 ppm for DNP and TNP were sought.

The problem was solved by the GAM implemented in the *fgoalattain* routine from the Optimization Toolbox of Matlab®. Using this routine implicated adapting the weight values, w_i. Due to the way *fgoalattain* was built, the "opposite rules" were considered, which means that w_i was set lower for the more important objectives, and negative to make an objective function greater than the goal. Setting up the weights requires having in mind the industrial targets, where it is undoubtedly far more critic to reach 100% of MNB than 0 ppm of DNP and TNP. Accordingly, and after an iterative sensitivity study, the weights for MNB were set in the range $1x10^{-8}$ to 0.03, while the weights for DNP and TNP were kept constant and equal to -1.

As expected, it can be seen in *Figure 4* that when MNB increases the by-products formation also increases. In *Figure 5* the results are presented for TNP and we can clearly verify that the major contributor for the nitrophenols (NP's) is DNP. As a matter of fact, for the optimum solutions obtained, TNP can be considered negligible. The results for the other process variables T, *a* and F_B/F_N are similar to the pattern in Figure 4. For a fixed residence time it is clear that to achieve a lower NP's formation with consequent MNB reduction, T, *a* and F_B/F_N must decrease, which means that lower values of these variables reduce the extension of the main and side reactions. Moreover the magnitude of these process variables decreases for increasing residence time.

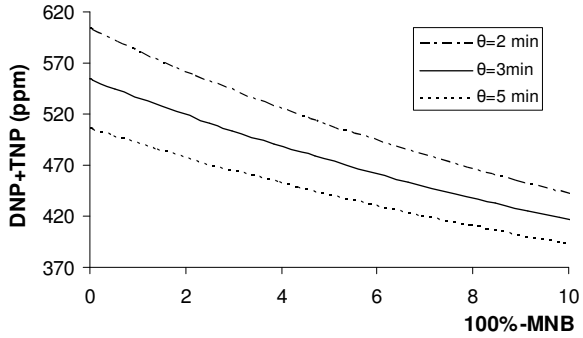

Figure 4 – Pareto front for the total NP's in the interest region of MNB>90% as a function of the θ upper limit constraint.

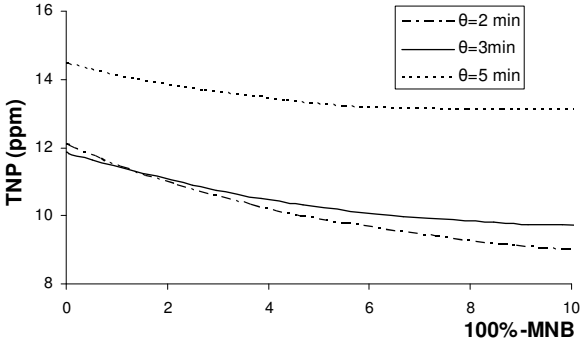

Figure 5 – Pareto front for the TNP in the interest region of MNB>90% as a function of the θ upper limit constraint.

NA and SA optimum values are constant and equal to 3.1% and 66.6% respectively, as it was already observable in the scatter plot in *Figure 3*. The residence time contribution to the optimum values can be wrongly interpreted if we only consider selectivity. In fact, for a higher residence time the same MNB concentration is achieved with fewer secondary products. Nevertheless the MNB production is lower for a higher residence time.

3 Conclusions

In this work we presented an optimization framework for addressing the achievement of adequate trade-off evolution for the benzene nitration process in terms of the concentrations of the main and by-products. In particular, it puts at the disposal of a decision maker a set of Pareto fronts in an interest region of MNB concentration greater than 90%, providing optimum solutions in a granted feasible region. The results obtained can be further exploited by introducing economical information in the tradeoffs formulations.

Abstract

The numerical solution of dynamic optimization problems has been intensively investigated through indirect and direct methods, genetic algorithms, dynamic programming and hybrid methodologies. Several experimental studies confirm the yield and productivity increments of ethanol in the fed-batch fermentation but the results are highly dependent of the microorganism and substrate, filling times, feeding strategy and substrate concentration and are applicable to restrict conditions (Xiong & Zhang, 2003; Bravo *et al*., 2000; Carvalho *et al*., 1993, 2005; Laopaiboon *et al*., 2007). In this paper the optimal feeding strategy to maximize ethanol production from sugarcane is calculated considering conditions and constraints representative of Brazilian industrial conditions. The parameters of the Andrews kinetic model (1968) were estimate by Differential Evolution for high fed substrate concentrations using S*accharomyces cerevisiae* from batch and fed-batch experiments. The resulting differential-algebraic dynamic optimization problem is solved by the control and state parameterization method trough Dircol code (von Stryk, 1999). The control and state variables profiles are presented and the influences of factors like substrate concentration and filling rate on the optimal profiles are evaluated.

1 Introduction

Modak et al. (1986) classified the fermentative processes according to the form of the specific rates of growth of cells and formation of product, from the analysis of the maximum points. The optimal sequence of the phases was determined in function of the specific rates and the initial conditions of the process. Srinivasan et al. (2003) focuses on interpreting the various arcs that constitute the optimal solution in terms of the path and terminal objectives of the optimization problem, such as the cost, constraints and sensitivities.

The Dircol code is a set of FORTRAN subroutines to solve multi-phase Optimal Control Problems (OCP) described by differential equations subject to inequality and/or equality constraints on the state and/or control variables. The parameterization of state and control variables is done by direct collocation, transforming the OCP into a NLP which is solved through dense Sequential Quadratic Programming (SQP) by NPSOL code (Gill et al., 1986).

The main goal of this paper is to apply the Pontryagin's Minimum Principle (PMP) to identify the singular control strategy and to use the Direct Method implemented in Dircol code (von Stryk, 1999) to maximize the ethanol production for *Saccharomyces cerevisae* fed-batch fermentation from sugarcane. Previous studies are related to *Zymomonas mobilis* or adopt operational restrictions and kinetic models that do not represent the conditions adopted by Brazilian industries, some of them presenting yield higher than 0.511[g/g] for glucose as substrate, justified by less accurate kinetic models (Hong, 1986; Chen & Hwang, 1990; Xiong & Zhang, 2003). The challenge to solve a singular problem with differential index fluctuation

*Corresponding author. Tel +55 (02134) 3239-4292 Ramal 229. e-mail: valeria@ufu.br

is added to the development of accurate and simple enough mathematical models of a nonlinear process with complex metabolism, for control and optimization purposes.

This paper is presented as following. Section 2 presents the mathematical model of fed-batch reactor. Section 3 presents the necessary conditions for optimality and optimal feeding strategy. In Section 4 one case study is presented and finally the conclusions are summarized in Section 5.

2 Problem Formulation for Fed-Batch Fermentation

In fed-batch fermentation, the process is represented by the following mass balance equations:

$$\frac{d(XV)}{dt} = \mu XV; \quad X(0) = X_0 \qquad (2.1) \qquad \frac{d(SV)}{dt} = FS_f - \sigma XV; \quad S(0) = S_0 \qquad (2.2)$$

$$\frac{d(PV)}{dt} = \pi XV; \quad P(0) = P_0 \qquad (2.3) \qquad \frac{dV}{dt} = F; \quad V(0) = V_0 \qquad (2.4)$$

where X, S and P stand for the concentration of cell mass, substrate, and product respectively; F stands for the substrate feed rate; S_f is the feed substrate concentration; V is the bioreactor volume; and μ, σ, π are the specific rates of growth, substrate consumption and product formation, respectively. X_0, S_0, P_0 and V_0 are the initial conditions. Constraints are imposed on the final bioreactor volume and on the substrate feed rate (Eq. 2.5 and 2.6):

$$V(t_f) \le V_{max} \qquad (2.5) \qquad 0 = F_{min} \le F \le F_{max} \qquad (2.6)$$

The objective is to determine the optimal feed profile, F, which maximize the Objective Function $\Phi \equiv PV(t_f)$ with free final time t_f. Let the amounts of cells, substrate, and product be denoted by $x_1=XV$, $x_2=SV$, $x_3=PV$, and be $x_4=V$. If t_f appears explicitly, as in this case, and additional state variable, x_5, is introduced (with $dx_5/dt=1$ and $x_5(0)=0$). Then $x_5(t_f)= t_f$ and the original system is given by:

$$\frac{d}{dt}\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} \mu x_1 \\ -\sigma x_1 \\ \pi x_1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 0 \\ S_f \\ 0 \\ 1 \\ 0 \end{bmatrix} F \quad \Rightarrow \quad \dot{x} = a(x) + bF; \quad x(0) = x_0 \qquad (2.7)$$

3 Necessary Conditions for Optimality and Optimal Feeding Strategy

The system to be solved is described by Eq. (2.7) subject to Eq. (2.5) and Eq. (2.6). Defining the Hamiltonian as:

$$H \equiv \lambda^T a(x) + \lambda^T bF = \psi(x,\lambda) + \phi(\lambda)F \qquad (3.1)$$

where the adjoint vector must satisfy the following:

$$\frac{d\lambda}{dt} = -\frac{\partial H}{\partial x} = -\left[\frac{\partial a}{\partial x}\right]^T \lambda; \quad \lambda_i = -\frac{\partial \Phi}{\partial x_i} \qquad (3.2)$$

Since control F appears linearly in the Hamiltonian, the optimal control which minimizes the Hamiltonian can be determined examining the sign of ϕ:

$$F = \begin{cases} F_{\max} & if \ \phi < 0 \\ F_{sing} & if \ \phi = 0 \\ F_{\min} & if \ \phi > 0 \end{cases} \tag{3.3}$$

Thus, the optimal feed rate sequence may consist of nonsingular intervals and singular intervals. According Bryson and Ho (1975), since on a singular interval ϕ is identically zero over a finite interval, all of its time derivatives must also vanish:

$$\phi = 0 \tag{3.4}$$

$$\frac{d\phi}{dt} = 0 \tag{3.5}$$

$$\frac{d^2\phi}{dt^2} = 0 \tag{3.6}$$

For the case where μ, σ and π are functions of substrate concentrations, the Hamiltonian is given by:

$$H \equiv \psi + \phi F = (\lambda_1 \mu - \lambda_2 \sigma + \lambda_3 \pi) x_1 + \lambda_5 + (\lambda_2 S_f + \lambda_4) F \tag{3.7}$$

The adjoint equations are given by:

$$\dot{\lambda}_1 = -(\lambda_1 \mu - \lambda_2 \sigma + \lambda_3 \pi) = -(\psi - \lambda_5)/x_1 \tag{3.8}$$

$$\dot{\lambda}_2 = -(\lambda_1 \mu' - \lambda_2 \sigma' + \lambda_3 \pi') x_1 / x_4 \tag{3.9}$$

$$\dot{\lambda}_3 = 0 \tag{3.10}$$

$$\dot{\lambda}_4 = (\lambda_1 \mu' - \lambda_2 \sigma' + \lambda_3 \pi') x_1 x_2 / x_4^2 \tag{3.11}$$

$$\dot{\lambda}_5 = 0 \tag{3.12}$$

On the singular interval $\phi = 0$ and thus $\psi = H^*$. Using the equations (3.4), (3.5) and (3.8) yields three equations in five adjoint variables, which must be satisfied on the singular arc:

$$\lambda_1 \mu - \lambda_2 \sigma + \lambda_3 \pi = (H^* - \lambda_5)/x_1 \tag{3.13}$$

$$\lambda_2 S_f + \lambda_4 = 0 \tag{3.14}$$

$$\lambda_1 \mu' - \lambda_2 \sigma' + \lambda_3 \pi' = 0 \tag{3.15}$$

Equation (3.15) may be substituted into Eq. (3.9) and Eq. (3.11) to obtain:

$$\dot{\lambda}_2 = \dot{\lambda}_4 = 0 \tag{3.16}$$

which implies that λ_2 and λ_4 are constant on the singular arc. The singular control is obtained from Eq. (3.6):

$$(\lambda_1 \mu'' - \lambda_2 \sigma'' + \lambda_3 \pi'') \dot{S} + \dot{\lambda}_1 \mu' = 0 \tag{3.17}$$

Equation (3.17) may be solved by $\dot{S}$:

$$\dot{S} = -\dot{\lambda}_1 \mu' / (\lambda_1 \mu'' - \lambda_2 \sigma'' + \lambda_3 \pi'') = (H^* - \lambda_5) \mu' / [x_1 (\lambda_1 \mu'' - \lambda_2 \sigma'' + \lambda_3 \pi'')] \tag{3.18}$$

For free time problems in which the objective function is independent of the final time have $H^* = 0$ and $\lambda_5 = 0$, thus the feed rate on singular interval is:

$$\dot{S} = (H^* - \lambda_5) \mu' / [x_1 (\lambda_1 \mu'' - \lambda_2 \sigma'' + \lambda_3 \pi'')] = 0 \Rightarrow F_s (S_f - S)/V - \sigma x / V = 0 \tag{3.19}$$

Equation (3.19) shows that the substrate concentration may be kept constant on singular arc. This constant value of substrate concentration (*S**) can be obtained solving equations (3.13) and (3.15):

$$\frac{\pi'\sigma - \sigma'\pi}{\mu'\sigma - \sigma'\mu} = -\frac{\lambda_1}{\lambda_3} \tag{3.20}$$

As $H^* = 0$ and $\lambda_5 = 0$, this implies that λ_1 is constant from beginning of singular arc until final time. Thus we may write $\lambda_1(t) = \lambda_1(t_f)$ and $\lambda_3(t) = \lambda_3(t_f)$, since λ_3 is constant over entire optimal control path. Hence, Eq. (3.19) may be rewritten as:

$$\frac{\pi'\sigma - \sigma'\pi}{\mu'\sigma - \sigma'\mu} = -\frac{\lambda_1(t_f)}{\lambda_3(t_f)} = -\frac{0}{-\dfrac{\partial\Phi}{\partial x_3}} = 0 \tag{3.21}$$

Thus, switching to the singular arc is possible only when the substrate concentration in the bioreactor satisfies Eq. (3.21).

In this way, in the previous established strategy control consists in the following phases with constant-singular-constant control:

- *First phase*: as the initial substrate concentration is zero, $F = F_{max}$ to rapidly increase the substrate concentration to $S=S^*$ (calculated by equation (3.21));
- *Second phase*: when *S** is reached this constant substrate concentration must be maintained so that the control variable F is calculated to satisfy $dS/dt=0$, until the maximum volume of the reactor is reached;
- *Third phase*: when the constraint in maximum volume is satisfied, the singular phase arrives to end and $F = F_{min}$ (batch phase).

4 Results and Discussion

The dimensionless parameters of Andrews's kinetic model given by Eq.(4.1) were estimated by Differential Evolution and the values μ_{max}, K_S, K_i and M_S are, respectively, 0.3135, 0.1199, 0.5949 and 0.05523. Equations (4.2) and (4.3) define the specific rates substrate consumption and product formation as function of yields Y_{xs} and Y_{ps}.

$$\mu = \mu_{max}\left(\frac{S}{K_S + S + \dfrac{S^2}{K_i}}\right) \quad (4.1) \qquad \sigma = \left(\frac{1}{Y_{XS}}\mu + M_S\right) \quad (4.2) \qquad \pi = \frac{Y_{PS}}{Y_{XS}}\mu \quad (4.3)$$

Table 4.1 presents the singular substrate concentration, the switching times t_{s1} and t_{s2} which identify each phase, the final fermentation time and the objective function for two different feed substrate concentration and considering two maximum values of control variable F. The results were obtained through Dircol code with tolerance 10^{-5}, five grid points by phase and assuming the following range for switching and final times: $0< t_{s1}<4$, $4< t_{s2}<7$ and $7< t_f <18$. It can be observed that the increasing of F_{max} value have no significative influence on final fermentation time and product formation, resulting in a light decreasing of time and increasing of *pV*. As expected, the first phase becomes short-range with decreasing of t_{s1} values and consequent increasing of singular phase.

Table 4.1 Switching times, final time and objective function.

s_F (g/L)	*S** (g/L)	F_{max} (L/h)	t_{s1} (h)	t_{s2} (h)	t_f (h)	*pV* (g)
216.6	57.8610	0.6598	2.7208	5.9115	12.6110	386.0925
		1.6500	0.4431	5.7373	12.5067	386.1175
285.1	76.1433	0.6598	1.7125	7.4970	16.6181	461.3241
		1.6500	0.4116	7.3553	16.4593	461.3525

Otherwise, the product formation pV increases significantly with S_f associated with the increase of final time fermentation. Figures 1 to 10 present the simulated cells, substrate, product, volume and control profiles, where the three mentioned phases may be clearly identified.

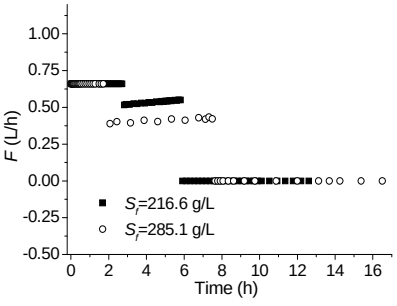

Figure 9: Control variable profiles (u_{max}=0.6598 L/h).

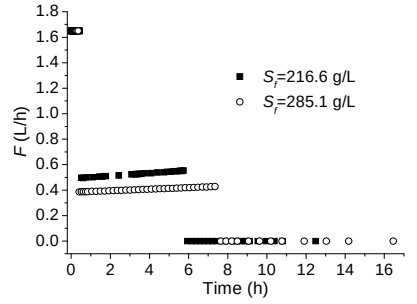

Figure 10: Control variable profiles (u_{max}=1.6500 L/h).

5 Conclusions

The methodology presented consists in the application of PMP to define the characteristics of singular arc in each phase and use of control and state parameterization though Dircol code to maximize de productivity of fed batch ethanol fermentation from sugarcane. It was shown that at singular arc the substrate concentration should be maintained constant at value S*. The increasing of S_f causes the decreasing of first switching time, shortening the range of the first phase and lengthening the singular phase with consequent increasing on final fermentation time and productivity. It should be observed that the proposed methodology is based on the process operating conditions and optimization goals to define the sequence of events. It is also dependent of the characteristics of the model equations, which in its final formulation should be necessary well posed.

Selection of controlled Variables for Complex Distillation Column with Heat Pump

M. Ebrahiminejad ,R. Eslamloueyan*
Petroleum and Chemical Engineering Department, Shiraz University, Shiraz, Iran

Keywords: Controlled variable selection, Distillation column, Heat-integrated, self-optimizing control
Topic: Systematic methods and tools for managing the complexity (Process control & operations)

Abstract

A complex distillation column with heat pump that separates propylene and propane is considered for control configuration selection. The column is an industrial C3 splitter used for producing polymer grade propylene. The overhead vapour is compressed so that it can condense in the shell side of the column reboiler and produce the needed boilup at the bottom. The method of self optimizing control is employed for selection of controlled variables. The proposed strategy is based on selecting the most economical controlled variables according to steady state condition of the process. The controlled variables are those output variables that when kept at their constant setpoints cause the disturbed process to stay near an economic optimum. The results show that the ratio of the boilup rate to reflux flowrate has the least loss, from the view point of self optimizing strategy.

Introduction

Distillation columns used for highly pure separations of close boiling mixtures are extremely energy consuming. Low relative volatilities and high product purity lead to very large reflux ratios and subsequently large amount of energy consumption in the column condenser and reboiler. In addition, if the components being processed have low boiling points then cooling water cannot be used in the condenser and expensive low temperature refrigeration system have to be installed. Some improvement methods have been recommended for such columns to decrease cost of energy. These modifications are mainly based on optimizing the process in steady state conditions so, if they were applied on the process then the control and operation of the column would become very difficult. Using a heat pump is one of the heat integration methods to reduce the consumption of energy in the distillation columns. It is usually applied in the columns when the temperature difference between the overhead and the bottom is small. Propylene and propane splitters, being used to produce polymer grade propylene, are placed in this category of columns. Several types of heat pumps have been suggested and used for C3 splitter in the industry. Direct vapor recompression is the most frequent heat pump system in propylene-propane separation when the distillate is a good refrigerant.

Finco and Luyben (1989) studied the control of a conventional distillation column with low relative volatilities used for separation of propylene and propane. They performed both dynamic and steady state modeling. In the case of dual composition control, they examined several control structure. Based on the Relative Gain Array (GRA), they concluded the reflux flow rate and bottom flow rate (R, B) should be used as manipulated variables. Muhrer et al. (1990) studied the control of vapour recompression distillation columns with reference to C3 splitter and ethanol/water

* Fax:+98-711-6287294 , Email: eslamlo@shirazu.ac.ir ; reslamloueyan@yahoo.com

separation. They stated that the control system used on these two specific vapour recompression columns could be the same as the control system of conventional columns. They replaced heat input control by compressor control. Papastathopoulou and Luyben (1991) did a comprehensive study of the dynamics and control of a large industrial column with 190 trays and a high reflux ratio. They used a steady state model to calculate steady state gains for a large number of alternative controls. Several control indices were calculated, such as the Morari resiliency index (MRI), the Relative Gain Array (RGA), the Niederlinski index (NI). They showed that the most effective control structure depends on the control objectives. Gokhale, Hurowitz, and Riggs (1995) compared dual composition control performance for a diagonal proportional integral PI controller and several advanced controllers. They observed significant improvement in performance for the multivariable controllers over the PI controller for a periodic variation in feed composition. Hurowitz et. al. (1998) studied a propylene and propane column on Distillation control configuration selection. They found that the reflux flow rate and bottom flow rate (R,B) and the reflux flow rate and boilup flow rate to bottom flow rate ratio (R,V/B) configurations were the best control configurations. They also observed that the distillate flow and bottom flow rates (D,B) configuration with tight level control provided roughly equivalent results. Enagandula and Riggs (2006) presented a technique to evaluate control configuration selection for distillation columns by developing closed-loop Bode plot using a linear dynamic tray-to-tray model of the process. They concluded based on the results for the product variability prediction, the ratio of reflux to distillate flow rates and boilup flow rate (R/D, V), the ratio of reflux to distillate flow rates and the ratio of boilup to bottom flow rates (R/D, V/B) and the distillate flow rate and bottom flow rate (D, B) (with tight level control) configurations provided the best overall control performance. Olujic et. al. (2006) introduced internally heat integrated (HIDiC) version of a state of the art propylene-propane splitter as an economically attractive option for new designs, provided the barriers related to increased design complexity could be overcome.

A self-optimizing control method (Skogestad, 2000) presents a mathematical procedure for selection of controlled variables. In this method, a cost or profit function is formulated as quality of operation that would be minimized or maximized. The optimum value of cost function is calculated in normal condition of the process when no disturbances exist in the process. A set of controlled variables are selected and kept constant at their setpoint values. The disturbances are introduced to the process for each group of controlled variables in the set and, the cost functions are estimated for each group separately. The difference between the cost function of disturbed process and optimum nominal value of cost function is called loss function. That group of variables having the least value of loss function is considered as the variables being controlled. Mathematical definition of the concept gives:

$$L(cs,d)=J(cs,d)-J(opt) \quad (1)$$

As a result with proper selection of controlled variables there is an acceptable loss without a need to repeat the optimization again. The feature of the self-optimizing control method is that the control scheme is obtained based on the steady state simulation of the .

Industrial C3 Splitter with Heat Pump

Fig. 1 shows flowsheet of the industrial C3 splitter studied in this work. The distillation heat pump (DHP) system consists of a vapor compression cycle loop. The type of the condenser/reboiler heat exchanger is shell and tube. The compressor has a variable speed motor.

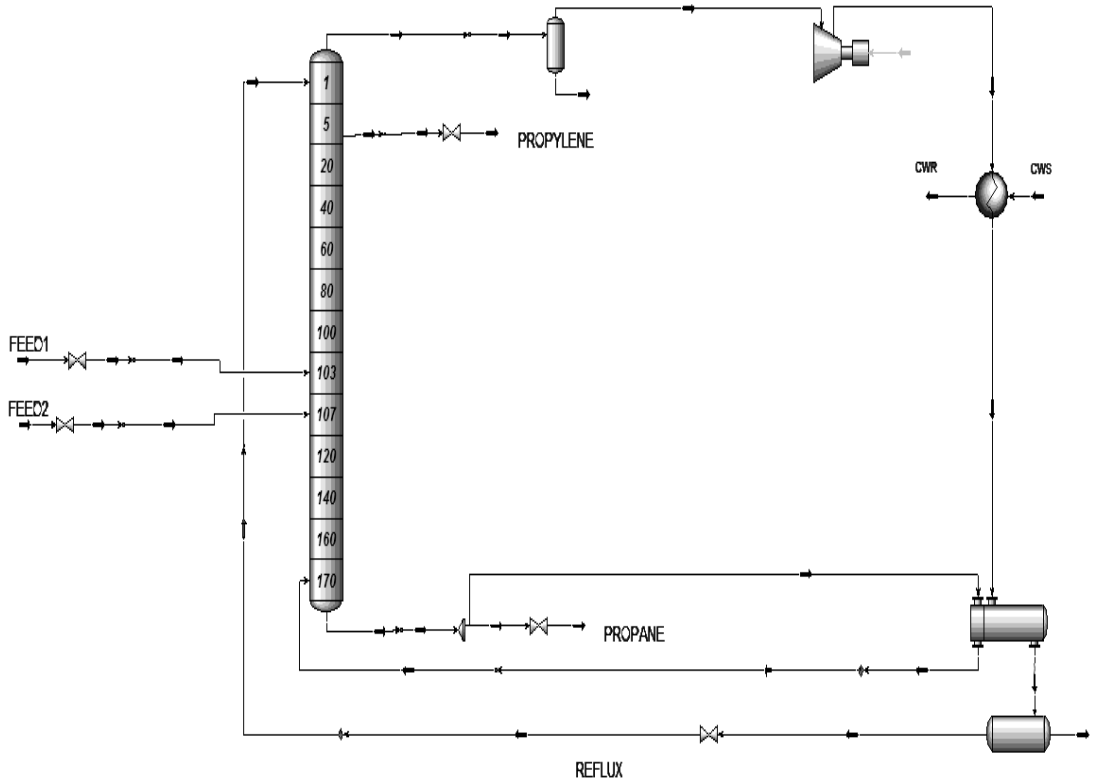

Fig. 1 flowsheet of the process

TABLE 1
Steady state data

Variable	Variable description	Steady state value
F_1	First feed flow rate	61.63 (kmol/hr)
z_{F1}	First feed composition	0.9556
q_{F1}	First feed liquid fraction	1.0
F_2	Second feed flow rate	259.86 (kmol/hr)
z_{F2}	Second feed composition	0.9200
q_{F2}	Second feed liquid fraction	1.0
D	Top product flow rate	300.0 (kmol/hr)
B	Bottom product flow rate	21.5 (kmol/hr)
x_D	Top product composition	0.995
x_B	Bottom product composition	0.1
N_{tot}	Total number of trays	170
P_{top}	Column pressure	10 (barg)
N_{F1}	First feed tray location	103
N_{F2}	Second feed tray location	107

The discharge vapor of the compressor is desuperheated by cooling water in a cooler before entering the shell side of the condenser/reboiler exchanger. Overhead vapor is compressed to a higher pressure, to prepare heat duty for boiling bottom liquid. In this way condenser and reboiler duties are coupled and, then the cooling water consumption of for separation is reduced. The Steady state data of the column are reported in Table 1. The process was simulated by Hysys simulator.

Self optimizing control method

The self-optimizing method has the following six steps:

A. Determination of degrees of freedom

In this step, the number of manipulated variables are considered as the degree of

freedom. The distillation plant in Fig. 1 has 7 control degrees of freedom: two feedrates, reflux flowrate, distillate and bottom product flowrates, compressor speed, and cooling water flowrate. For distillation column case study there are two holdups in the reboiler/condenser heat exchanger that have to be stabilized then two degrees of freedom are consumed. If it is assumed that two feedrates are fixed then it leaves three degrees of freedom for optimization.

B. Definition of cost function and constraint

In the second step, the cost function is formulated as the operating cost defined by the following equation.

$$P = -J = (p_D D + p_B B - p_{F_1} F_1 - p_{F_2} F_2 - p_s W_s - p_{cw} V_{cw}) \quad (2)$$

Where W_s and V_{cw} are the power consumption of the compressor and volumetric flow rate of the cooling water, respectively With given feedrates, F1 and F2 are fixed and, the related terms have no effect on the cost function. After the economic objective is defined, the system constraint must be determined. The following two constraints were specified:

- The pressure of column should be greater than or equal to 10 bar.
- The product purity of the distillate should be above or equal to 99.5%.

Table 2. Loss calculation results

Var.	Variable description	F1-20%	F1+20%	F2-20%	F2+20%	F2-20%	z_{F1}-10%	z_{F1}-10%

C. Identification of important disturbances

The most important disturbances are ±20% variation in each of the two feed flowrates,

10% decrease in each of two feed composition.

D. Steady state optimization

After simulation, the optimization problem is done to determine nominal steady state operating point, when there are no disturbances. The values of optimal operating point are chosen as setpoint of candidate controlled variables. Optimization is repeated when the disturbances occurring to obtain optimum cost function.

E. Identification of sets of candidate controlled variable

As it is mentioned, there are four constraints that should be controlled at their setpoints: the pressure of the column, the purity of the distillate product, and two holdups in reboiler/condenser heat exchanger. Therefore one of the degrees of freedom remains for self optimizing control. The alternative controlled variables, considered in this study, are shown in Table 2.

F. Evaluation of the loss

To determine the best controlled variable, the losses were calculated for each candidate controlled. The results of the loss evaluation are presented in Table 2.

The comparison of economic losses in Table 2 suggests that the best controlled variable is V/L and, the other controlling candidates are operationally feasible.

Conclusion

In this paper the primary controlled variable is selected based on self-optimizing method for a distillation column with heat pump. The software Hysys is used both to simulating and optimizing the process. For the distillation column case study there are five degrees of freedom. Four of them are consumed for two holdups and two active constraint, i.e. column pressure and distillate product purity. A number of alternative controlled variables were compared with respect to their calculated losses. Based on the loss calculation, the ratio of boilup rate to reflux rate is found as the best controlled variable for the remaining degree of freedom.

Abstract

This paper describes a new Model Predictive Control (MPC) algorithm inspired on Statistical Process Control (SPC) paradigms, to handle systems represented by linear state-space models with stochastic disturbances. It is considered that a linear discrete-time process model is identified based on operational data, and employed to propagate states and outputs within the control horizon. The uncertainty of the states due to model parameters is also projected, taking into account model realization and innovation terms described by normal probability distribution functions (pdfs). The optimal sequence of actions is formulated as a non-linear programming problem whose objective function accounts for the probabilistic cost of quality variables falling outside the product specifications. The strategy proposed is demonstrated with a system comprising two inputs and two quality variables, representing the dynamics of a precipitated calcium carbonate plant.

1 Introduction

Model Predictive Control is an approach nowadays highly disseminated at the industrial level and well studied by the research community, especially when dealing with complex units. Additionally, model robustness has become a fundamental topic in the design of Model Predictive (MP) controllers. This property, assessing the stability properties of the closed-loop system in the presence of plant-model mismatches, has been extensively studied for unconstrained systems (Morari and Zafiriou, 1989). Similar analysis relative to MPC constrained systems has also been addressed in a number of works (e.g, Michalska and Maine (1993)). A classic approach to address the problem of robust MPC considers worst-case scenarios (Lee and Yu, 1997): however, this strategy often leads to conservative performance. Therefore, practical solutions require often better performance in the presence of stochastic disturbances, for systems described by uncertain parameters. This is particularly relevant when the purpose is to control quality variables subject to market specifications.

The monitoring of modern plants involve the acquisition of thousands of signals, later stored in large databases. This source of knowledge might be employed to build process data-driven models. Several tools devoted to this task have received significant attention in recent years, and are nowadays common at the industrial level. For example, linear discrete state-space models offer a simple representation of

*Corresponding author. Tel. +351-239-790720. E-mail: bduarte@isec.pt.

system dynamics incorporating stochastic components to describe either uncertainties in the parameters or non-stationary features (Durbin and Koopman, 2001).

An MPC formulation accounting for the two sources of uncertainty (parameters uncertainty and inflows variability) has emerged in the later years as a framework able to provide MPC with the ability to incorporate probabilistic constraints in the so-called chance-constrained MPC (Schwarm and Nikolaou, 1999; Li et al., 2008). Here we exploit the ideas behind the chance-constrained MPC formulation to determine optimal controllers able to cope with uncertainty. However, such a formulation treats the probabilistic features as constraints, aiming to address the problem of robustness when stochastic inputs appear. Here, the classic optimization MPC problem is reformulated to incorporate the probabilistic cost of failing to fulfill the quality specifications, thus explicitly evaluating the effects of uncertainties in the objective function. This modification relies on the conceptual paradigms of SPC, where probabilistic quality losses represent potential costs (Alwan, 2000). Moreover, it is also in close agreement with the MPC formulation of Batina et al. (2002), to handle linear systems subject to stochastic disturbances, with state and input constraints.

2 An SPC inspired MPC formulation

Let us consider a process represented by a discrete state space model

$$x(t+1|t) = A\,x(t|t) + B\,u(t|t) + K\,e(t|t) \tag{1a}$$

$$y(t|t) = C\,x(t|t) + D\,u(t|t) + e(t|t) \tag{1b}$$

where $x \in \mathbb{R}^{\mathrm{s}}$ is the process state, $u \in \mathbb{R}^{\mathrm{u}}$ are the input variables, $y \in \mathbb{R}^{\mathrm{y}}$ the output variables, and $e \in \mathbb{R}^{\mathrm{s}}$ represents the stochastic component. A, B, C, D and K are time independent parameter matrices, and $x(t+1|t)$ represents the forecast of the states at the discrete instant $t+1$ given the value at t. The input variables include disturbances, here designated as d, with $d \in \mathbb{R}^{\mathrm{d}}$, and manipulations, designated as $c \in \mathbb{R}^{\mathrm{c}}$, with $\mathbb{R}^{\mathrm{u}} \equiv \mathbb{R}^{\mathrm{d+c}}$. The vector of outputs includes quality variables $q \in \mathbb{R}^{\mathrm{q}}$ and non-controlled outputs $\bar{q} \in \mathbb{R}^{\bar{\mathrm{q}}}$, with $\mathbb{R}^{\mathrm{y}} \equiv \mathbb{R}^{\mathrm{q}+\bar{\mathrm{q}}}$. Thus:

$$\begin{bmatrix} q(t|t) \\ \bar{q}(t|t) \end{bmatrix} = \begin{bmatrix} C_q \\ C_{\bar{q}} \end{bmatrix} x(t|t) + \begin{bmatrix} D_q \\ D_{\bar{q}} \end{bmatrix} u(t|t) + \begin{bmatrix} e_q(t|t) \\ e_{\bar{q}}(t|t) \end{bmatrix} \tag{2}$$

The identification of model (1) based on process data, considering missing observations, was discussed by Gândara et al. (2006). The uncertainty affects the inputs with the innovation for each state described by a normal pdf $\mathcal{N}(0, \sigma^2)$. The joint pdf is represented by $\mathcal{N}(0, \Sigma)$, where $\Sigma = \mathrm{Cov}(e)$ is the variance-covariance matrix of states uncertainty. The MPC formulation derived above, based on time-discrete models, can be easily extended to first principles models including uncertain parameters.

Figure 1 presents the classic model-based control scheme for a SISO system when uncertainty is explicitly considered, and when joint/individual pdfs describing the controlled quality variables are evaluated by means of their moments, at each discrete time instant. The process states and outputs are forecasted within the control horizon employing equations (1), without the stochastic component. One may see that the quality variables at any time instant $t+i$ are influenced by the process state at time t and all control actions implemented $u_{t+j},\ 0 \le j \le i$.

On the other hand, the uncertainty is also projected in the control horizon employing the discrete-time model. Here, $\epsilon(t+i|t)$ represents the prediction error of the quality variables at time instant $t+i$, when t is the present instant. Thus

$$\epsilon(t+i|t) = \left[C \left(\sum_{j=0}^{i-1} A^j \right) K + I \right] e(t|t) + C\,A^{i-1}\,e_{x0} \tag{3}$$

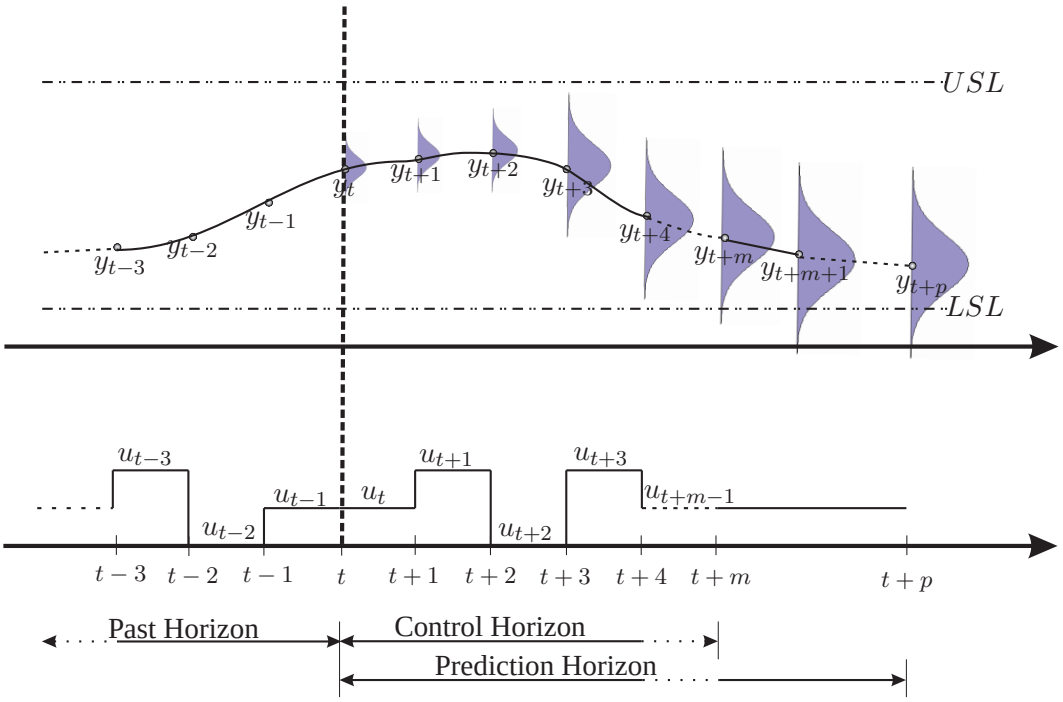

Figure 1: MPC representation for models including parameter uncertainty.

where e_{x0} stands for the uncertainty of the process state at time t. The prediction error variance, $\chi(t+i|t),\ 0 \leq i \leq p$, where p is the dimension of the prediction horizon, is to be estimated employing the propagation formulas developed by Seppala (1998):

$$\chi(t+i|t) = [\Psi(t+i|t) \bullet \Psi(t+i|t)]\ \mathrm{Cov}(e) + [\Omega(t+i|t) \bullet \Omega(t+i|t)]\ \mathrm{Cov}(e_{x0}) \tag{4a}$$

$$\Psi(t+i|t) = \begin{cases} C\ \sum_{j=0}^{i-1} A^j\ K + I & \text{if} \quad i > 0 \\ I & \text{if} \quad i = 0 \end{cases} \tag{4b}$$

$$\Omega(t+i|t) = \begin{cases} C\ A^{i-1} & \text{if} \quad i > 0 \\ I & \text{if} \quad i = 0 \end{cases} \tag{4c}$$

where $[\Psi \bullet \Psi]$ stands for the Hadamard product of matrices Ψ. Those equations allow the analytical determination of the joint pdf of the quality variables, considering the linear characteristics of the system, under the assumption that for each time instant the pdf is given by a q-dimensional normal distribution. The matrix $\chi(t+i|t)$ is formed by four-block matrices, with $\chi_{q,q}(t+i|t)$ used to represent the uncertainty of the quality variables:

$$\chi(t+i|t) = \begin{bmatrix} \chi_{q,q}(t+i|t) & \chi_{\bar{q},q}(t+i|t) \\ \chi_{q,\bar{q}}(t+i|t) & \chi_{\bar{q},\bar{q}}(t+i|t) \end{bmatrix} \tag{5}$$

where $\chi_{q,q}(t+i|t)$ stands for the variance-covariance matrix of the prediction error of quality variables q at discrete time instants $t+i$.

The probabilistic cost of producing out of specification is defined by the hyperplane of values θ belonging to the space $\Re^{\mathrm{q}}$, with $\{\theta : \theta \leq [LSL^1, \cdots, LSL^{\mathrm{q}}]^{\mathrm{T}} \wedge \theta \geq [USL^1, \cdots, USL^{\mathrm{q}}]^{\mathrm{T}}\}$, where LSL and USL are lower and upper quality specifications, respectively. The probability of failure at each time instant is determined by the joint pdf, considering the state and error variance estimates:

$$p_f(t+i|t) = 1 - \int_{LSL^1}^{USL^1} \int_{LSL^2}^{USL^2} \cdots \int_{LSL^{\mathrm{q}}}^{USL^{\mathrm{q}}} \frac{1}{\sqrt{2\,\pi}\ |\chi_{q,q}(t+i|t)|} \times$$
$$\times \exp[-(\theta - q(t+i|t))^{\mathrm{T}}\ \chi_{q,q}^{-1}(t+i|t)\ (\theta - q(t+i|t))]\ \mathrm{d}\theta^1\ \mathrm{d}\theta^2 \cdots \mathrm{d}\theta^{\mathrm{q}} \tag{6}$$

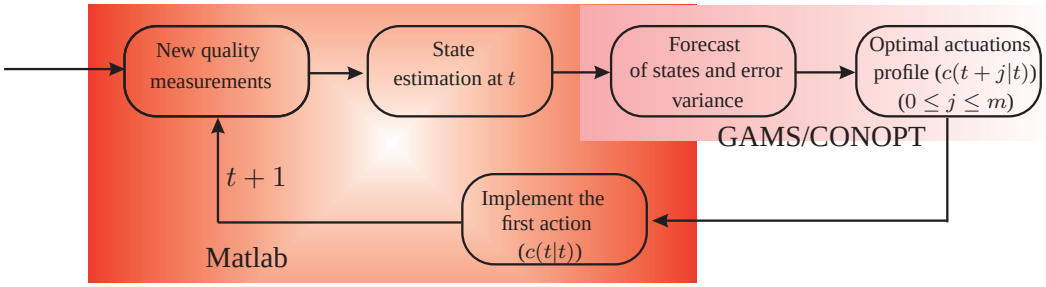

Figure 2: Stochastic MPC information flows.

The analytical evaluation of the q-dimensional integral included in Equation (6) has obvious advantages over numerical approaches based on Hammersley sampling (Diwekar and Kalagnanam, 1997) and cubature formulas (Bernardo et al., 1999). However, such a strategy cannot be applied for non-linear models, since the joint pdf is non-gaussian and its evaluation consequently rather complex.

The MPC optimal control problem falls into the class of non-linear programming (NLP), and is solved with the GAMS/CONOPT solver using a formulation

$$\min_{c} \sum_{i=1}^{m} p_f(t+i|t) \tag{7a}$$

$$\text{s.t.} \quad \text{Equations (1, 4, 6)} \tag{7b}$$

$$c^L \leq c(t+i|t) \leq c^U, \qquad \forall i,t \tag{7c}$$

where c^L and c^U are lower and upper boundaries of the manipulation variables. The problem (7) is solved at each time instant, and the first action, $c(t|t)$, implemented (see Figure 2). Then the prediction horizon is updated to start at the next time instant, new quality variables measured, the problem is solved again and another action is implemented. The estimate of the process state at time instant t is performed based on the observations of the past horizon and on the process model. The window employed for state estimation is updated at every discrete time to account for new observations. A Matlab-based interface is used to re-iterate the calculation sequence.

3 Application

Here we consider the control of a precipitated calcium carbonate (PCC) production plant. The quality variables controlled are the average diameter, designated as quality variable 1, and the specific surface area of the PCC particles, named quality variable 2, resulting from the reaction between lime particles and CO_2. The main disturbance is the granulometry of the lime particles that flows into the reactor, quantified by its average diameter and represented as d_1, and the variable employed for controlling the process is the flow of CO_2, represented as c_1. The time discrete model was identified from process data after convenient variable scaling, and time-independent parameter matrices are presented below. It is noticeable that the model obtained, optimal regarding the Akaike's criterion, includes four process

states, with $u = \begin{bmatrix} d_1 & c_1 \end{bmatrix}^{\mathrm{T}}$:

$$A = \begin{bmatrix} 0.1366 & 0.0811 & -0.0052 & -0.0203 \\ 0.0129 & 0.9631 & -0.2474 & -0.1023 \\ 0.0005 & 0.1386 & 0.6645 & -0.3611 \\ 0.0431 & 0.0516 & 0.2792 & -0.0684 \end{bmatrix}, \qquad B = \begin{bmatrix} -0.0002 & 0.0234 \\ 0.0020 & -0.0020 \\ -0.0206 & 0.0010 \\ 0.0085 & -0.0004 \end{bmatrix}$$

$$C = \begin{bmatrix} 16.5016 & 2.3803 & -0.1114 & -0.0979 \\ 0.0223 & 4.2695 & 0.2905 & 0.1180 \end{bmatrix}, \qquad K = \begin{bmatrix} 0.0076 & 0.0110 \\ 0.0605 & 0.1399 \\ 0.0424 & 0.0118 \\ 0.0149 & -0.0038 \end{bmatrix}$$

$$\mathrm{Cov}(e) = \begin{bmatrix} 0.0023 & 0.0008 \\ 0.0008 & 0.0016 \end{bmatrix}, \qquad \mathrm{Cov}(e_{x0}) = 8.33 \times 10^{-4}\, I_{4\times 4}, \qquad D = 0_{2\times 2}$$

$$LSL = \begin{bmatrix} -1.0000 & -0.7500 \end{bmatrix}^{\mathrm{T}}, \qquad USL = \begin{bmatrix} 1.0000 & 0.75000 \end{bmatrix}^{\mathrm{T}}$$

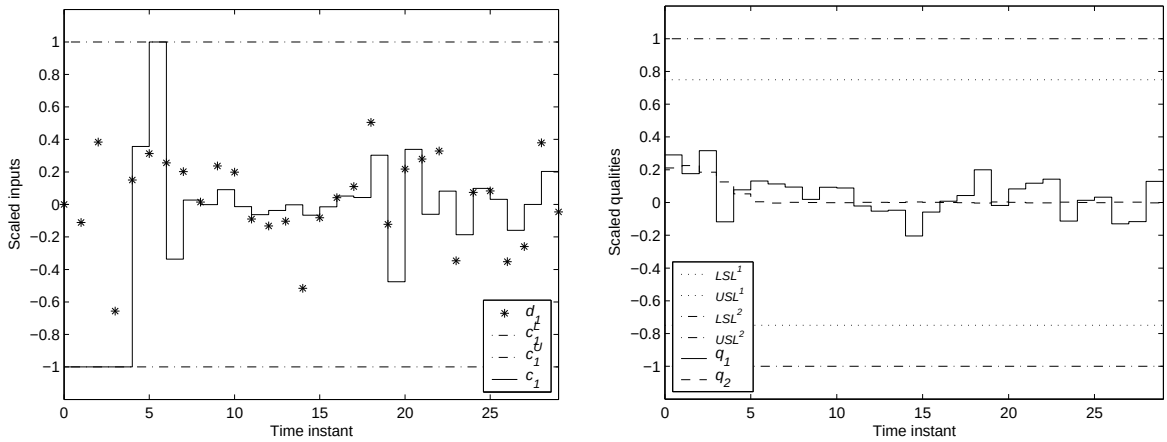
$$c^L = \begin{bmatrix} -1.0 \end{bmatrix}^{\mathrm{T}}, \qquad c^U = \begin{bmatrix} 1.0 \end{bmatrix}^{\mathrm{T}}$$

The process involves two quality variables and a single manipulated variable, corresponding to the second component of u. Although there exists a certain degree of correlation between the quality variables, captured by a previous time series analysis of the data, the structure will lead to a non-perfect controller. Indeed, the optimal manipulations profile trade-off the quality variables losses, which means that the objectives of each one could not be exactly reached. The forecasting horizon is set to 10, the past horizon dimension is 20, and all signals available in the past horizon (quality variables and inputs) are used to update the process state, x_t. The optimal control problem is solve to a relative tolerance of 10^{-6}, and the limits of the manipulated variable are presented above.

Figure 3(a) presents the manipulations and the disturbance profiles for a window comprising 30 sequential discrete time instants. The disturbance dynamics was simulated employing the normal pdf identified from original process data, $d_1 \approx \mathcal{N}(0, 0.35)$. The value of the disturbance is maintained constant in the prediction horizon. Figure 3(b) presents the dynamics of quality variables. One may see that the manipulation variable reaches the saturation limit at the beginning of the run, as a result of the process state in the first instants being totally determined by past data. It is also shown that the second quality (specific area) is tightly controlled, while the first one exhibits larger variations. This behavior is partially due to the inability of the controller to achieve an optimal performance for both qualities simultaneously, since a single manipulation variable is available. The manipulation actions are chosen to primarily stabilize the second quality variable, which could result in larger probabilistic losses. The propagation of the uncertainty of this variable leads to broad expectation distributions, which can be seen comparing the columns of the matrix K, providing that the values of the $\mathrm{Cov}(e)$ are of the same order of magnitude. Thus, the control of the quality variable 2 is more accurate than the control of quality 1; however, in the optimal solution the probabilistic quality losses due to the latest become similar to the losses due to the former.

4 Conclusions

This paper describes a new MPC formulation inspired by the SPC paradigm, to account for the uncertainty of model parameters. The basic formulation stands on linear state-space discrete time models identified from process data, but can be extended to other model families. The model is employed to propagate states and quality variables within the prediction horizon. The uncertainty, described by the pdf of predictions, is represented by a multi-dimension normal distribution, and propagated taking into account the model innovations. The optimal control problem is then formulated aiming to minimize the loss of quality associated to quality forecasting, falling into the class of NLP problems. The determination of the probability of failure is handled analytically by integrating the normal pdf representing the



(a) (b).

Figure 3: Simulation results: (a) Inputs profiles; (b) Quality variable profiles.

qualities expectation. The approach presented is demonstrated by controlling a process with two quality variables, four states, and two inputs (one manipulated variable and a disturbance), representing the model of a plant devoted to the production of PCC. The MPC algorithm introduced can be extended to trade-off the costs of failure with the costs of the manipulation actions and the costs of measuring discretely the qualities to assess additional information to reduce the uncertainty of the forecasts. To address these problems the basic approach presented only requires a reformulation of the objective function of the optimal control problem. Another aspect to look at is the use of sampling algorithms to numerically determine the quality loss, which allow us to broaden the application of this approach to non-linear models and non-gaussian uncertainty forms.

Topic: Systematic methods and tools for managing the complexity

Abstract

The main tool of the computer aided process engineering is the process simulation (Biegler, 1989). One of the main objectives of the simulation is allowing the creation of models in steady-state or in transient regime of the performance of a plant, under defined conditions and through the development of process material and energy balances (Glasscock and Hale, 1994).

The study, here reported, corresponds to the use of a process simulator to develop a model of the distillation unit of the fuel plant of the Petrogal Porto Refinery. The results of the studies performed with the process simulator demonstrated that this tool allows developing models applied to the reality that are very useful to evaluate different operational scenarios.

1 Introduction

In mathematical point of view, a simulation problem corresponds to obtain a solution of a high number of equations which represents the performance of the unit operations and the behaviour of the chemical compounds.

The simulation is very relevant in several working areas of the refinery processes, such as:

Conception/Design – Study of different design alternatives and determination of the operation values, to determine good solutions, using economic drivers, safety rules and/or environment control requirements;

Start up – Prediction of operational conditions during the starting up of the processing units;

Operation – Study of limit operation conditions attending to safety rules and the possible modifications in the project specifications;

Optimization – Modification of the operational values with the objective to evaluate the operational conditions which minimizes the economic, energy and environmental requirements. In this case, the simulation has been demonstrated as a good strategy to maximize the profit through the reduction of consumption and/or by increasing the production, for the installed equipment.

The main steps in simulation are: i) the problem definition; ii) the development of the process model; iii) the collection of additional data; iv) the resolution of the model equations, and finally v) the analysis of the results.

One simulation problem is defined through a sequence of steps which are: i) the selection of components, ii) the selection of the appropriate unit operations, iii) the creation of the process flow diagram, iv) the selection of the correlations to evaluate the thermodynamic

* Corresponding author. Tel + 351-22-5081974. E-mail:fgm@fe.up.pt

properties, and iv) the introduction of the information related with streams, equipment and operation.

The distillation unit of the Petrogal Porto fuel plant consists in three main sections, focused on three distillation columns (T3001, T3004 and T3005). Figure 1 presents a schematic diagram of the installation. The column T3001 is the principal column which separates the crude oil into different fractions. The T3004 (naphtha splitter) separates the heavy naphtha into gasoline (bottom product) and a top product, which is fed to the T3005 column. This column (debutanizer) has as products the gases (top product) and light gasoline (bottom product).

Crude oil is heated previously through 7 heat exchangers and a furnace (H3001), forming the heating system. The temperature of crude oil at the entrance of the main column of atmospheric distillation is a crucial variable, very important for the performance of the total plant.

The principal heating supplier to the column T3001 is the furnace (H3001). Additionally, there are also several streams of steam injected to the columns T3001, T3002 and T3003 which allow to introduce heat in system and to rectify kerosene, diesel and residue. The three columns (T3001, T3002 and T3003) are designated by the topping unit. This group has a total of 4 products. The top product (naphtha) is fed to the T3004 column. The bottom product (residue) from T3001 column is for storage. The remaining 2 products are the lateral products of the T3002 and T3003 columns, corresponding to kerosene and diesel, respectively.

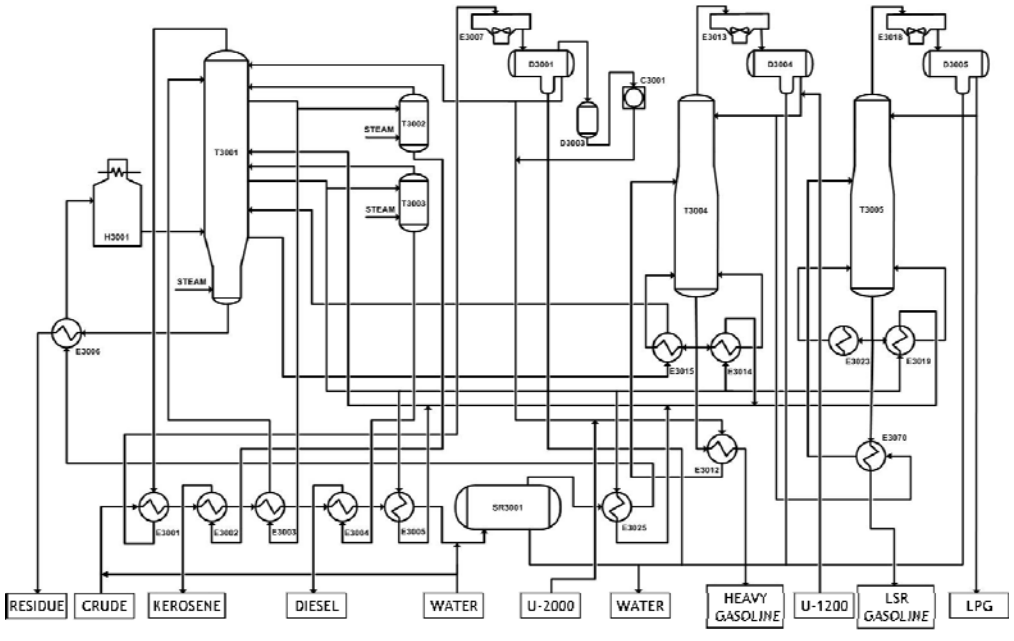

Figure 1 – Diagram of the fuel plant distillation unit.

The software used was the PRO/II which is a steady-state simulator. This software performs rigorous mass and energy balances for a wide range of processes. PRO/II combines the data resources of a large chemical component library and extensive thermodynamic property prediction methods with advanced and flexible unit operations techniques. PRO/II runs in an interactive Windows®-based GUI environment (http://www.simsci-esscor.com, 2008)

2. The procedure

The study, here reported, was developed in two phases: i) in the first phase, the objective was to obtain a performance model for the unit, comparing the results obtained by simulation with the operational values; and ii) in the second phase, some modifications in equipment were introduced, to evaluate the global performance of the unit for processing of a light crude oil.

The topping unit was designed, many years ago, to separate heavy crude oils. However, nowadays the crude oils are more light and as consequence the current plant is not well prepared to manipulate these types of crudes oils. Thus, it is very important to evaluate the performance of the plant, after installing new equipment that allows the separation of these new crudes oils.

Figure 2 (a, b, c and d) shows the current topping unit with three modifications which corresponds to three different scenarios:

Scenario 1 - the introduction of a drum to remove the light fractions of crude oil, being the top product of this column fed to the main column (Figure 2b);

Scenario 2 - the introduction of a pre-flash column, instead of a drum, to remove the light fractions of crude oil being the top product of this column fed to the main column (Figure 2c);

Scenario 3 - the introduction of a pre-flash column to remove the light fractions of crude oil, being the top product of this column fed the column T3004 (Figure 2d).

The main objective was to evaluate the impact of theses scenarios on the increase of the diesel yield and on the reduction of energy consumption.

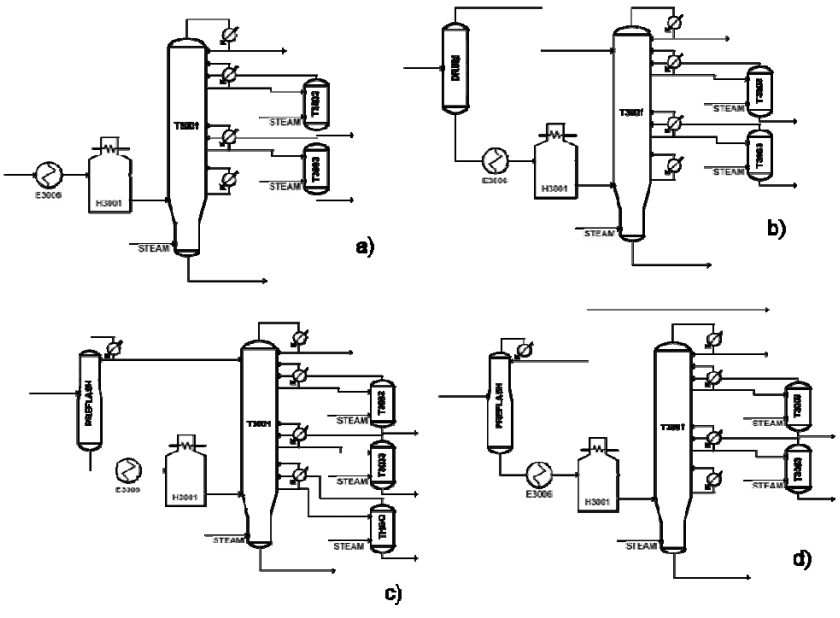

Figure 2 - Study cases with modifications of installed equipment.

It was also analysed the impact of the production of an additional product (heavy diesel) in the diesel yield, using the operational configurations suggested before. Figure 3 presents the different equipment configurations with the additional lateral product.

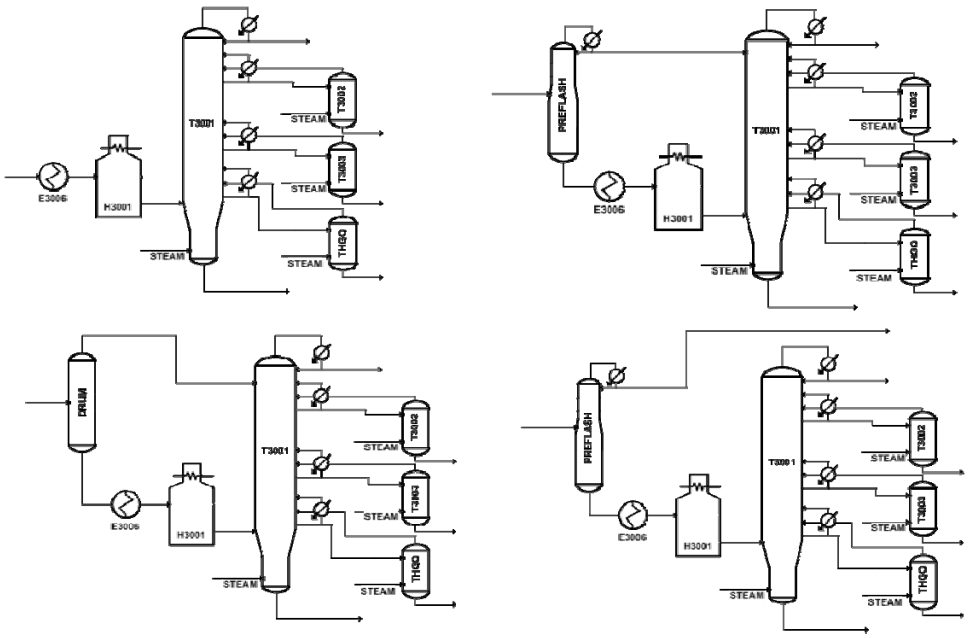

Figure 3 – Equipment configurations with the additional lateral product (heavy diesel).

3. Results and discussion

Figure 4 presents real data and the results obtained by simulation for the topping unit. As can be seen, the model adjusted clearly the real data.

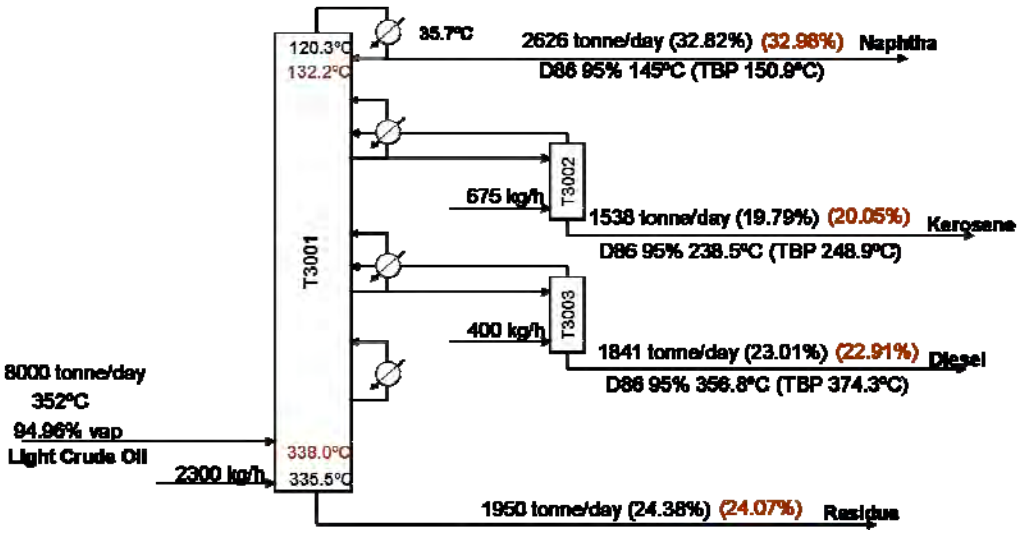

Figure 4 – Real data and results obtained by simulation (color values) for the topping unit.

Concerning the heating system, Figure 5 shows also that the model is able to simulate this system.

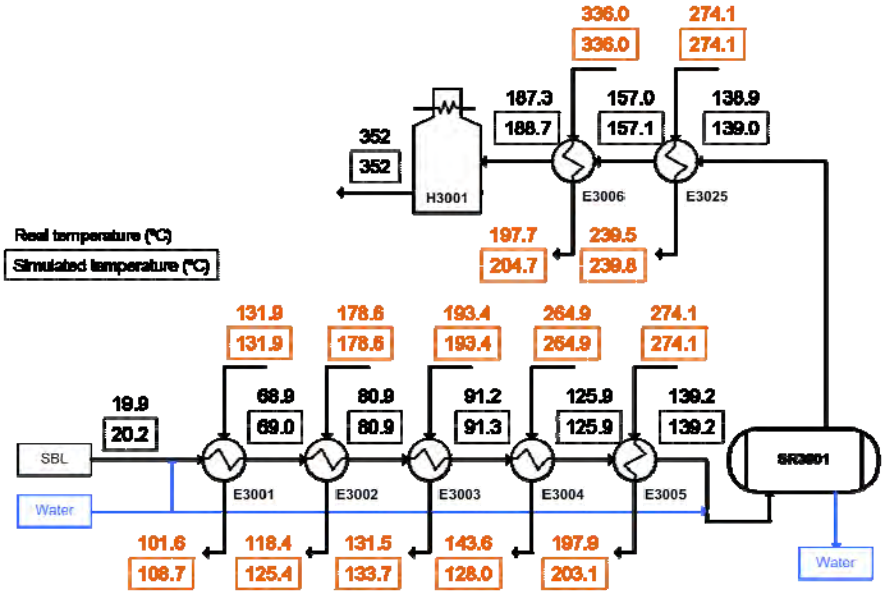

Figure 5 – Heating system (real data versus simulated results).

Table 1 shows the results obtained by the incorporation of new equipment in the plant, corresponding to the three scenarios describe before, using a light crude oil. The results allowed to conclude that the main impact of the introduction of a drum or a preflash in the unit is the decrease of duty of furnace H3001. Is was possible to verify that there wasn't no significant differences between the utilization of a drum or a preflash unit.

Table 1 – Results obtained for a light crude oil for the the diferent equipment scenarios.

	Base	**Drum**	**PreFlash**	**PreFlash with bypass**
Duty H3001 (Gcal/h)	49.76	40.71	41.94	42.81
Vapour at H3001 outlet (%)	94.96	90.71	91.22	91.50
Duty Condenser T3001 (Gcal/h)	32.62	28.94	23.74	23.91
Yield Naphtha (%)	32.82	32.85	32.10	21.33(*)
Yield Kerosene (%)	19.79	19.16	20.09	19.62
Yield Diesel (%)	23.01	23.26	23.10	23.15
Yield Residue (%)	24.38	24.74	24.71	24.68

(*) This value corresponds to the top product of T3001. The top product of the *Preflash* had a yield of 11.21%.

In what concern the production of an additional lateral product (heavy diesel). Table 2 presents the results obtained with the actual plant and the three scenarios described before, for a production a 15 m^3/h of heavy diesel, manipulating a light crude oil. The results indicated that all configurations obtained identical results. However, it was not possible to obtain a product with the target quality limits (heavy diesel TBP 5% and heavy diesel TBP 5% approximately equal to 380 ^oC and 420 ^oC, respectively).

Table 2 – Results obtained with the incorporation of an additional product (heavy diesel).

	Base	***Drum***	***PreFlash***	***PreFlash* with *bypass***
Yield Naphtha (%)	32.82	32.70	32.41	20.54 (*)
Yield Kerosene (%)	19.80	19.35	19.69	19.59
Yield Diesel (%)	23.15	23.34	23.33	23.30
Yield Heavy Diesel (%)	3.99	3.98	3.98	3.98
Yield Residue (%)	20.25	20.65	20.6	20.61
Diesel TBP 95% (ºC)	377.7	377.7	377.7	377.7
Heavy Diesel TBP 5% (ºC)	304.5	300.1	300.6	300.5
Heavy Diesel TBP 95% (ºC)	455.8	458.8	458.8	458.7
Residue TBP 5% (ºC)	360.9	357.9	358.9	358.8

(*) This value corresponds to the top product of T3001. The top product of the *Preflash* had a yield of 11.98%.

4. Conclusions

For the simulations performed for this plant, it was possible to conclude that:

1. The existing plant presents limitations to manipulate light crude oils because some columns are pratically at the flooding conditions;
2. The pre-separation can be beneficial by reducing the energy consumption of the furnace and for cooling at the top of T3001. However, this strategy is dependent of the type of the crude oil, being suggested for light crudes;
3. The studies developed with the inclusion of an heavy diesel lateral product demonstrated that the amount of this product is very low if the product is obtained within the specifications. So, it is not a relevant modification to be implemented for the processing of the light crude oil studied.

The results obtained by the simulations performed in this work demontrated that simulation is a very usefull tool to help analyzing possible revampings in refinery processes.

Keywords: CO_2 capture ; gas absorption ; dynamic simulation
Topic: Sustainable process-product development through green chemistry

Abstract

CO_2 capture from combustion flue gases is currently an issue of main interest due to the high taxes being imposed on industrial companies as a measure to achieve CO_2 emissions abatement. CO_2 capture can be efficiently achieved by gas absorption using amines, namely Monoethanolamine (MEA). Based on henrys law, validated with previously published experimental work, this study considers the development of a dynamic model of an absorption column for post combustion CO_2 capture. A dynamic model of the temperature swing de-absorption process was developed with the integration of both models for absorption and de-absorption (with the introduction of heat exchangers, pumps and other ancillary equipment). A control system for the process was also devised, comprising the pertinent sensors, and various control structures for the absorption column were tested and compared, such as single loop PID controllers (including the pairing problem) and MPC.

1. Introduction

CO_2 emissions result from a chemical reaction when fossil fuels are combusted to release stored chemical potential energy. This is, nowadays, the predominant source of world energy (about 86%) and has resulted in a marked increase on the CO_2 levels in the terrestrial atmosphere from 280 ppm in 1000, to 295 ppm in 1900 and about 377 ppm in 2004. CO_2 is not particularly toxic but is a major contributor to the greenhouse effect, which is most likely the cause of the climate change and increasing global heating over the Earths surface. Bearing in mind this situation, three main options arise to reduce total CO_2 emission into the atmosphere: i) to reduce energy intensity (which can be obtained by the efficient use of energy), ii) to reduce carbon intensity (which requires switching to using non-fossil fuels such as hydrogen and renewable energy), iii) to enhance the sequestration of CO_2. This third option involves the development of technologies to capture and sequester more CO_2.
There are, currently, many options for CO_2 separation and capture, and these include adsorption, absorption, membrane separations and biotechnology. The absorption/stripping process, using amine solutions such as monoethanolamine (MEA), is a commercialized technology used in natural gas industry for 60 years and is regarded as the most mature process and the CO_2 recovery rate can be as high as 98%. Nevertheless, the stability of the amines and the energy consumption of the stripping process, as well as the overall process control, have large room for further improvement.

2. Developed model

The typical process flow diagram for CO_2 removal process is shown in Figure 1. In this process, absorption of CO_2 by MEA takes place in the absorption column A, whereas stripping, for MEA recovery and recycling into the process takes place in stripper B. Other equipment consists of pumps, heat exchangers and, particularly, a reboiler E to supply stripping steam to increase the amine temperature reversing the chemical reactions and reducing the solubility of CO_2 in the liquid, thus releasing the CO_2 as a concentrated gas.

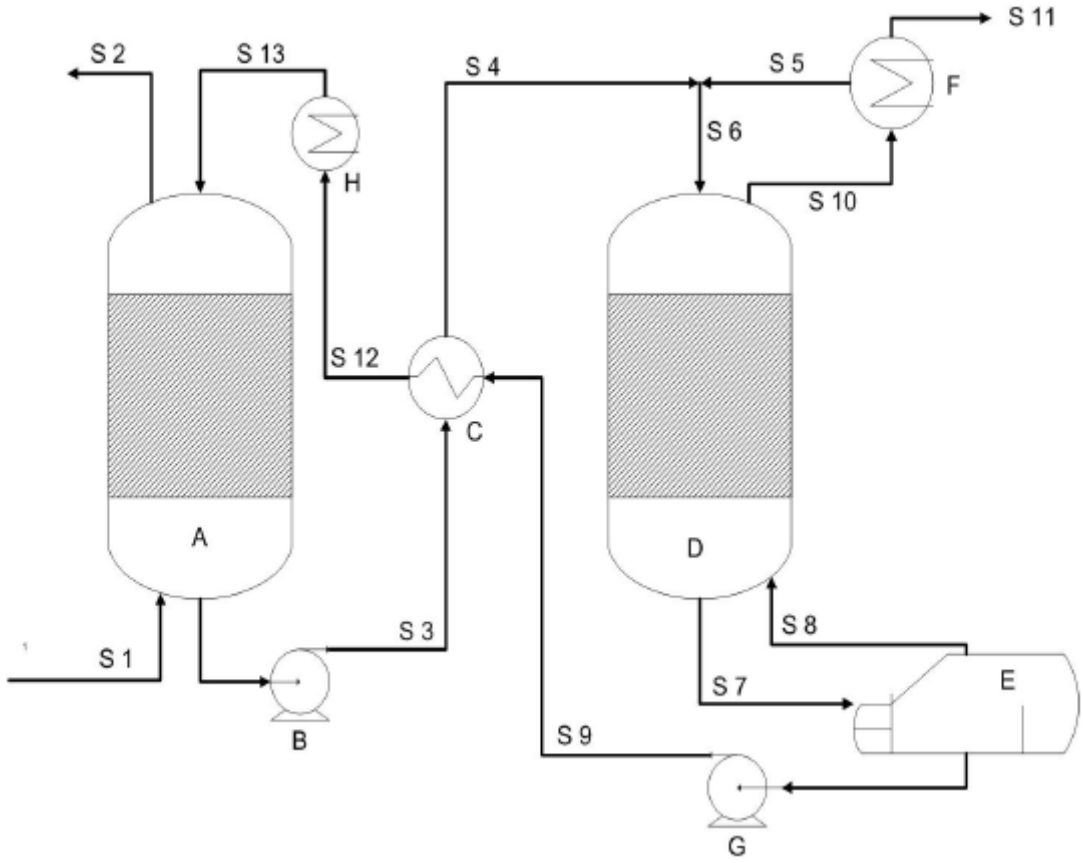

Figure 1. Process flow diagram of CO2 removal process using Monoethanolamine (MEA)

The model was constructed as a boundary condition PDE using Matlab and comprised a set of 6 chemical reactions occurring within the process and also the estimate of appropriate kinetics and thermo chemical properties such as density, viscosity, heat capacity, diffusivities and vapour liquid equilibrium. A schematic calculation flow sheet is presented in Figure 2.

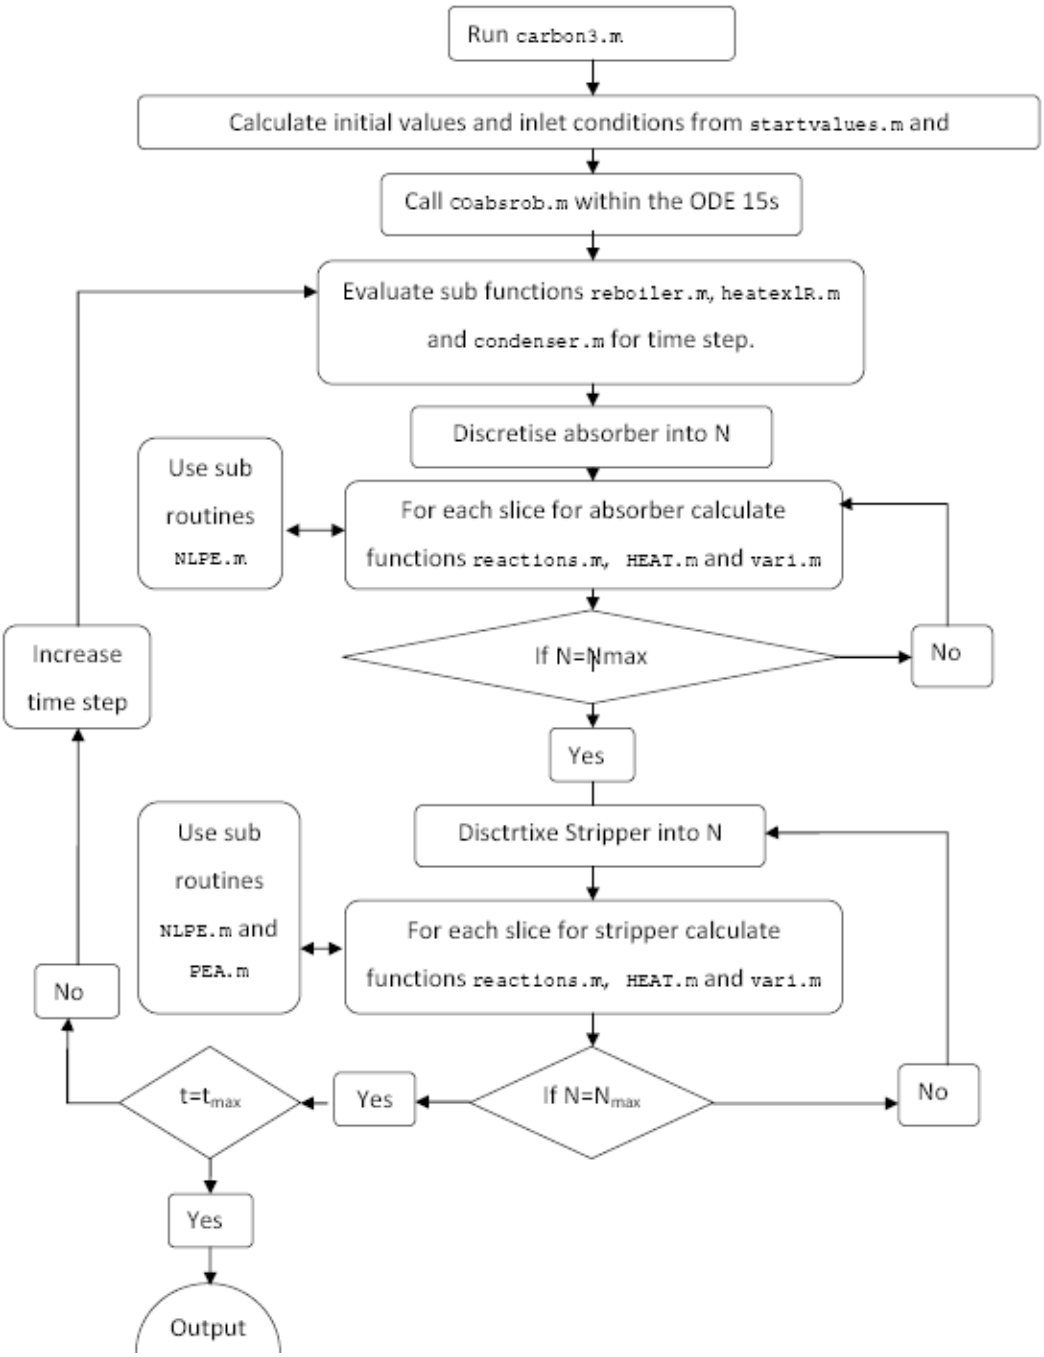

Figure 2. Calculation flow sheet

3. Results and discussion

The obtained results were generated by simulation with 35 discretised volumes so that the accuracy is increased. It allowed a graphical representation of the concentrations of the several chemical species involved as shown in Figure 3 regarding CO_2 in the absorber. This plot clearly shows that the CO_2 is depleted from the entrance at the bottom of the absorption column until it leaves at the top. The removal percentage is estimated at 88%, which is the range estimated from literature. As expected the removal rate is higher at the bottom of the tower, decreasing as the concentration in the gas approaches zero. The height of the tower has a large effect on the removal rate as the higher the tower, the higher the retention time of the liquid and the gas phases. Other obtained plots were the temperature of the vapour and liquid phases as well as the other species in both phases such as H_2O, N_2, MEA, O_2 and the chemical species formed when CO_2 reacts with MEA.

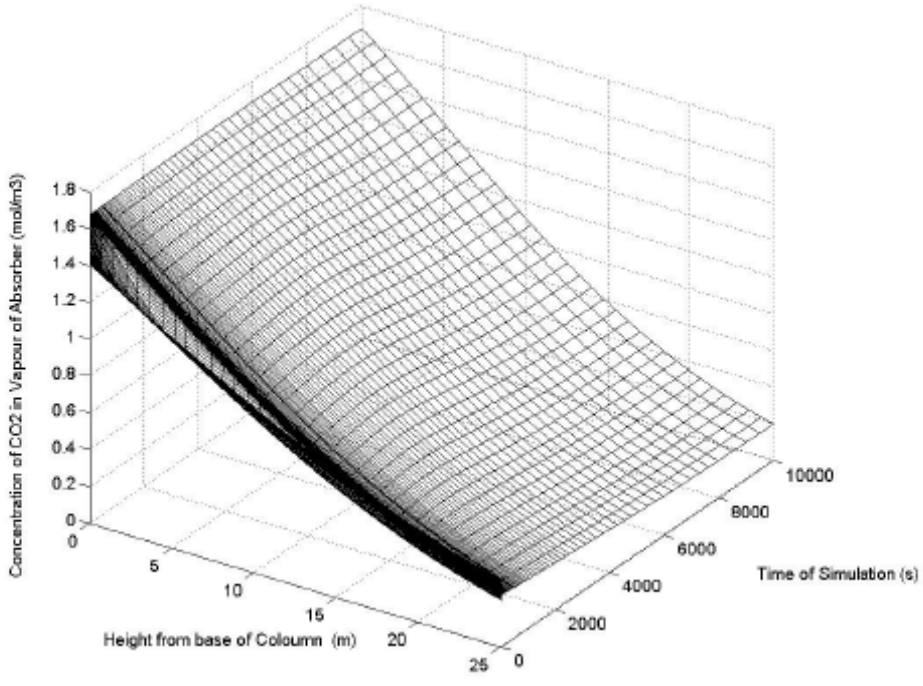

Figure 3. Obtained profile of CO_2 concentration in the absorption column

The developed model allowed for a sensitivity analysis of several operational and design parameters on the system. Table 1, shows some introduced variations ("perturbations") of the model from its baseline case. It is interesting to note the values for the CO_2 removal, energy consumption per kg of absorbed CO_2, cleaned gas composition and CO_2 loading for different parameters and inputs. The perturbations were run with 5 slices in the towers so that the results are not as accurate as with more slices, but do allow a quick overview of the controlling influences.

Table 1. Results of sensitivity analysis

	Base case	Perturbation	CO_2 removal rate (%)	Energy consumed (MJ/kg CO_2)	Cleaned gas (%)			CO_2 Loading (mol CO_2/mol MEA)	
					CO_2	MEA	H_2O	Lean	Rich

Stripper height (m)	**15**	*10*	78.6	4.05	36.7	0.17	63.1	0.253	0.416
Stripper diameter (m)	**5**	*7*	78.4	3.82	40.1	0.15	59.4	0.255	0.418
Amine solution volume flow rate (m^3/s)	**0.8**	*0.6*	70.3	3.41	39.8	0.14	60.0	0.257	0.453
Heat exchanger ΔT (K)	**10**	*5*	78.4	3.92	34.8	0.18	64.9	0.255	0.415
Inlet gas temperature (absorber	**313**	*333*	77.4	4.03	37.3	0.16	62.5	0.254	0.415
Inlet liquid temperature (absorber) (K)	**318**	*333*	78.3	3.95	38.7	0.16	61.1	0.258	0.423
Condenser reflux rate (%)	**10**	*30*	78.9	4.05	43.2	0.15	56.6	0.251	0.413
Reboiler temperature	**394.2**	*394.5*	84.9	6.37	18.5	0.31	81.2	0.198	0.366
Pressure reboiler (Pa)	**20000**	*190000*	88.7	28.47	3.6	0.51	95.8	0.15	0.31
Temperature liquid exiting condenser (K)	**380**	*330*	78.7	4.02	37.6	0.16	62.2	0.253	0.416
Packing used	**Montz**	Pall	66.1	4.52	34.3	0.19	65	0.253	0.38

Some important results could be noted, as follows:
i) absorber height: increasing the absorber height from 25 to 30 m, increases the removal rate from 78.7 to 83.4%, the energy required per kg removed is decreased by 2.5% and the cleaned gas has a higher proportion of CO_2. The main disadvantage is the increased capital cost.

ii) absorber diameter: decreasing the absorber diameter from 16 to 13 m, reduces the cross sectional area from 196 to 136 m^2, increasing the vapour and liquid velocities and reducing also the fluid retention time in the tower. The net result is a drop in the removal efficiency of 6% and an increase in the energy used per kg recovered of 6%. The advantage is that the capital cost is lower.
iii) stripper height: decreasing the stripper height from 15 to 10 m drops the removal rate slightly and increases the removal cost per kg also. The reactions and mass transfer take place more quickly at the elevated temperature of the stripper and, therefore, the controlling factor in the stripper is the equilibrium constants which dictate how much aqueous CO_2 is released from the bound CO_2 in other ions.
iv) stripper diameter: increasing the stripper diameter from 5 to 7 m, increases the cross sectional area of the stripping column from 20.5 to 37 m^2, effectively halving the fluid velocities. The longer retention time results in removing a larger amount of CO_2, increasing the cleaned gas proportion and decreasing the energy requirements by 5%. This is obtained at the expense of increased capital cost.
v) reboiler temperature: increasing the reboiler temperature increase the amount of vapour that is flashed in the reboiler. A higher vapour load decreases the lean loading as more of the MEA is regenerated. This results in an increased CO_2 removal percentage and a higher energy cost. It can be noted that increasing the temperature by only 0.3 K increases the removal rate by 2.5% and the energy consumed by 12%. The outlet from the condenser also contains a larger proportion of water vapour.

Also a typical control philosophy that could be implemented is:

a) rich amine pump B controls volumetric liquid flow rate to a given set point
b) lean pump G is controlled to keep a constant level in the bottom of the stripper
c) stream 13, the inlet liquid to the absorber, is controlled to a temperature set point by heat exchanger H
d) the de-absorption condenser F is used to control the temperature of S5 back to the stripper and the captured gas composition
e) the temperature and heat load to the reboiler E sets the temperature and flow rate of stream S8 which is the stripping steam.
f) with an MPC control philosophy the system can be optimised to find the minimum energy requirements but still remove the desired amount of CO_2

4. Conclusions

A dynamic model of CO_2 removal from a post combustion process was developed within this work, based on chemical absorption in MEA solution. The model comprises an absorption tower, de-absorption tower, reboiler, condenser, heat exchangers and pumps. Allowing for chemical reactions in the film with an enhancement factor is the easiest and least computational demanding method.
The residence time of the liquids in the absorption tower has a large effect on the results as the rate of CO_2 transfer is strongly dependent of the amount of surface area available for transfer. Increasing the absorption tower diameter and height produce a higher removal rate as the volume of inside packing is increased.
The de-absorption process is controlled by the equilibrium constants which dictate how much soluble CO_2 is released from the bound CO_2. At the elevated temperature in the stripper, the reactions proceed faster, the enhancement factor is greater and the diffusion process is increased.
The heat of reaction in the absorber adds heat to the liquid and gas phase increasing the temperature. In the stripper, the reactions are reversed and require energy as are endothermic. The higher the MEA concentration, the lower the energy requirements as less energy is required to heat the bulk fluid to a temperature to reverse the chemical reactions.
It was also noted that the overall system is very nonlinear with very fast reaction rates through to much slower diffusion rates and temperature transfer making the model computationally demanding. There are many parameters and inputs which affect the results

and finding an optimal solution is a challenging task especially if one includes the balance between capital and operational cost. A significant amount of H_2O and MEA leaves the system with the exhaust gas and the purified stream. The addition of a water wash, post capture dehydration and MEA and water make up should also be included. Finally it should be noted that the model of a absorption and de-absorption process using amine solution is a complex problem with many interactions. In the developed model, many assumptions and simplifications have been made but the results are still reasonable.

Keywords: Fluidized bed, CFD, Multiphase flow, Kinetic theory
Topic: CFD & Chemical Engineering.

Abstract

In this study, a three-dimensional two-phase flow model based on the kinetic theory of granular flow (KTGF) was used to predict the behavior of a gas-solid fluidized bed. The model is based on a Eulerian description of the two phases, gas and particles, and is composed of a set of mass conservation and momentum equations for each phase. In this model, the k-epsilon turbulence model and multiphase mixture are used. In order to describe the behavior of several particles in a continuum, the kinetic theory of granular flow was used.

The geometry and numerical mesh were generated using ANSYS ICEM CFD software and the set of partial differential equations was discretized and solved using CFX. Simulation data were verified against data found in Samuelsberg and Hjertager (1996), who used a cold flow laboratory circulating fluidized bed and simulated a two-dimensional model. Results using this model show that the model agrees with the experimental data and predicts a flow behavior similar to that found experimentally. It predicts the core annulus flow, which is known from the literature.

1 Introduction

Fluidized beds are widely used in many operations in chemical, metallurgical, energy generation and especially petrochemical industries. Major applications are fluid catalytic cracking (FCC) risers and CFB combustor systems. Although fuidized beds are successfully and widely used in commercial industrial operations, much remains to be done due to the complexity of the gas-solid flow. No analytical tools that describe the influences of complex geometries, chemical reaction, internal reflux and heat transfer on the flow pattern in fluidized beds are available. With the increased availability of computers, mathematical models have been applied to predict the behavior of a fluidized bed and several models have been proposed. Gidaspow *et al.* (2004) carried out an extensive review of the models developed for the fluidized bed reactors and Peirano and Leckner (1998) reviewed turbulent gas-solid flow modeling in circulating fluidized beds.

Gas-particle two-fluid models, which treated the particle phase as a continuous fluid based on the Eulerian method, were widely employed in modeling gas-solid flow in the past several decades. A fundamental problem encountered in modeling the hydrodynamics of a gas-solid fluidized bed by the two-fluid method is how to include the stress of the particle phase in the particulate momentum equation. In the more recent two-fluid models, for the particle phase in dense gas-particle flow, the kinetic theory of granular flow has received attention and its use in Eulerian simulations has increased (Jenkins and Savage, 1983; Ding and Gidaspow, 1990; Gidaspow, 1994; Hrenya and Sinclair, 1997; Samuelsberg and Hjertager, 1996). The kinetic theory of granular flow is based on the kinetic theory of gases, first developed by

* Corresponding author. Phone + 55-19-3521-3963. E-mail:mori@feq.unicamp.br

Chapman and Cowling (1970). In this theory, the inter particle interactions are taken into account by adding the contribution of collisions between particles (Jenkins and Savage, 1983), which are the main mechanism of transport due to particulate phase properties.

The present study aims to simulate a three-dimensional two-phase flow model, based on the kinetic theory of granular flow (KTGF), to predict the behavior of a gas-solid fluidized bed, using a computational fluid dynamics technique.

2 Mathematical model

Based on Eulerian description of the phases, a multiphase computational fluid dynamics model for turbulent gas-solid flow is presented. The Eulerian approach considers the two phases, gas and solid, as a continuum. The conservation equations for the solid phase are based on the kinetic theory for granular flow (Gidaspow, 1994).

The governing equations for transient three-dimensional gas-solid flow are presented as follows:

The continuity equation for phase i (= g,s):

$$\frac{\partial}{\partial t}\left(\varepsilon_i \rho_i\right) + \nabla \cdot \left(\varepsilon_i \rho_i \vec{\upsilon}_i\right) = S_i^{\rho} \tag{1}$$

where the subscript i can denote gas or solid phase, ε is the volume fraction, ρ is the density, t is the time, $\vec{\upsilon}$ is the velocity vector and S^{ρ} is the source term for mass transfer between the phases. Hence, no mass transfer is allowed between the phases.

The gas phase momentum equation:

$$\frac{\partial}{\partial t}\left(\varepsilon_g \rho_g \vec{\upsilon}_g\right) + \nabla \cdot \left(\varepsilon_g \rho_g \vec{\upsilon}_g \vec{\upsilon}_g\right) = -\varepsilon_g \nabla p_g + \nabla \vec{\tau}_g + \varepsilon_g \rho_g \vec{g} + \beta_{gs}^{m}\left(\vec{\upsilon}_s - \vec{\upsilon}_g\right) \tag{2}$$

where $\vec{g}$ is the gravity vector, p is the pressure and β_{gs}^{m} is the two-phase drag coefficient.

The stress tensor of the gas phase can be written as

$$\vec{\tau}_g = \varepsilon_g \mu_g \left(\left(\nabla \vec{\upsilon}_g + \left(\nabla \vec{\upsilon}_g\right)^T\right) - \frac{2}{3}\left(\nabla \cdot \vec{\upsilon}_g\right)\vec{I} \right) \tag{3}$$

Here, μ is the shear viscosity.

The gas phase turbulence is modeled with the k-epsilon model.

The solid phase momentum equation:

$$\frac{\partial}{\partial t}\left(\varepsilon_s \rho_s \vec{\upsilon}_s\right) + \nabla \cdot \left(\varepsilon_s \rho_s \vec{\upsilon}_s \vec{\upsilon}_s\right) = \nabla \vec{T}_s + \varepsilon_s \rho_s \vec{g} + \beta_{gs}^{m}\left(\vec{\upsilon}_g - \vec{\upsilon}_s\right) \tag{4}$$

where the solid stress tensor, $\vec{T}_s$, is the sum of a collisional part and a kinetic part and may be formulated as

$$\vec{T}_s = \left(-p_s + \lambda_s \nabla \cdot \vec{\upsilon}_s\right)\vec{I} + \mu_s \left(\left(\nabla \vec{\upsilon}_s + \left(\nabla \vec{\upsilon}_s\right)^T\right) - \frac{2}{3}\left(\nabla \cdot \vec{\upsilon}_s\right)\vec{I} \right) \tag{5}$$

where λ_s is the solid phase bulk viscosity.

The total solid phase pressure, p_s, consists of two terms; one of them, p_s^{k+t}, is determined from Lun *et al.* (1984) and includes both kinetic and collisional pressures, as follows:

$$p_s^{k+t} = \rho_s \varepsilon_s \left[1 + 2(1+e)\varepsilon_s g_o\right]\theta \tag{6}$$

where e is the coefficient of restitution and g_o is the radial distribution function.

The other term, p_s^f, is caused by friction and collisions in the solid phase due to highly dense flow, as proposed by Johnson and Jackson (1987), as follows:

$$P_s^f = Fr\frac{\left(\varepsilon_s - \varepsilon_{s,min}\right)^n}{\left(\varepsilon_{s,max} - \varepsilon_s\right)^p} \tag{7}$$

where the values of the constants in Equation (7) are Fr = 0.05, n = 2, p = 3 and $\varepsilon_{s,min}$ = 0.55, as suggested by Van Wachen (1998).

The total solid phase pressure is then given by

$$P_p = P_p^{k+t} + P_p^f \tag{8}$$

The radial distribution function, adopted by Lun and Savage (1986), is

$$g_o = \left(1 - \frac{\varepsilon_s}{\varepsilon_{s,max}}\right)^{-2.5\varepsilon_{s,max}} \tag{9}$$

where $\varepsilon_{s,max}$, the maximum particle packing chosen is 0.62.

Equation (9) is appropriate for dilute flow.

In Equation (6), θ is the granular temperature related to the kinetic turbulent energy of the particle motion. Ding and Gidaspow (1990) proposed the following equation for granular temperature:

$$\theta = \frac{1}{15(1-e)} d_p^2 \left(\frac{1}{2}\left(\nabla \vec{v}_s + \left(\nabla \vec{v}_s\right)^T\right)\right) \tag{10}$$

where d_p is the particle diameter.

Solid phase bulk viscosity, λ_s, due to particle collisions (Lun *et al.*, 1984) and solid phase shear viscosity, μ_s, for dense and dilute flow (Hrenya and Sinclair, 1997) are given by the following equations:

$$\lambda_s = \frac{4}{3}\varepsilon_s^2 \rho_s d_s g_o (1+e)\sqrt{\frac{\theta}{\pi}} \tag{11}$$

$$\mu_s = \frac{5\sqrt{\pi\theta}}{96}\rho_s d_s \left[\left(\frac{1}{1+\frac{\lambda_{mfs}}{R}}\frac{1}{\eta g_o} + \frac{8\varepsilon_s}{5}\right)\left(\frac{1+\frac{8}{5}\eta(3\eta-2)\varepsilon_s g_o}{2-\eta}\right) + \frac{768}{25\pi}\eta\varepsilon_s^2 g_o\right] \tag{12}$$

where λ_{mfs} and η are given by

$$\lambda_{mfs} = \frac{d_p}{6\sqrt{2}\varepsilon_s} \tag{13}$$

$$\eta = \frac{1}{2(1+e)} \tag{14}$$

The gas-solid drag coefficient for $\varepsilon_g \le 0.8$ is based on the Ergun equation and is given by

$$\beta_{gs}^m = 150\frac{\varepsilon_s^2 \mu_g}{\varepsilon_g d_p^2} + 1.75\frac{\left|\vec{v}_s - \vec{v}_g\right|\varepsilon_s \rho_g}{d_p} \tag{15}$$

And for $\varepsilon_g > 0.8$, based on the Wen and Yu equation:

$$\beta_{gs}^{m} = \frac{3}{4} C_D \frac{\left|\vec{\upsilon}_s - \vec{\upsilon}_g\right| \varepsilon_s \rho_g}{d_p} f\left(\varepsilon_g\right) \tag{16}$$

where $f\left(\varepsilon_g\right) = \varepsilon_g^{-2.65}$, as used by Gidaspow and Ettehadieh (1983).

The drag coefficient, C_D, is related to the Reynolds number as follows:

$$C_D = \varepsilon_g^{-2.65} \max\left[\frac{24}{Re_p\, \varepsilon_g}\left(1 + 0.15\left(Re_p\, \varepsilon_g\right)^{0.687}\right)\right] \text{ for } Re_p < 1000 \tag{17}$$

$$C_D = 0.44 \text{ for } Re_p \geq 1000 \tag{18}$$

$$Re_p = \frac{\left|\vec{\upsilon}_s - \vec{\upsilon}_g\right| \rho_g d_p}{\mu_g} \tag{19}$$

3. Results and discussion

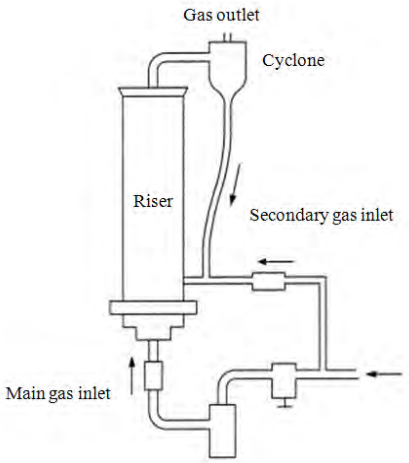
In order to validate the present numerical results, we compared them with the experimental results of Samuelsberg and Hjertager (1996). Then the simulations were carried out for the riser section of a circulating fluidized bed similar to that used by Samuelsberg and Hjertager (1996) and Mathiesen *et al.* (2000), shown in Figure 1 (a). In this study, just the riser section was simulated. The riser section is 1m high with an inner diameter of d = 0.032m. A secondary air supplier, positioned 0.05m above the gas inlet, feeds the solid back into the riser. The secondary gas inlet and the gas outlet have a diameter of 0.008m (Figure 1 (b)).The initial bed height is 0.05m and the initial solid volume fraction is 0.61. The system properties are defined in Table 1.

The riser section, as shown in Figure 1 (b), is modeled and simulated in a three-dimensional Cartesian coordinate system. Numerical predictions were obtained using the finite volume approach through the CFX-10 code, a CFD software developed by ANSYS, and the ICEM CFD code to generate the numerical grid, shown in Figure 1 (b). Numerical tests were conducted in order to optimize the computational grid. A grid of 300,000 control volumes was considered satisfactory considering the precision of the results (10^{-4}) and the computation time consumed. The time step used in all simulations was 10^{-3}s. The boundary conditions are summarized in Table 2.

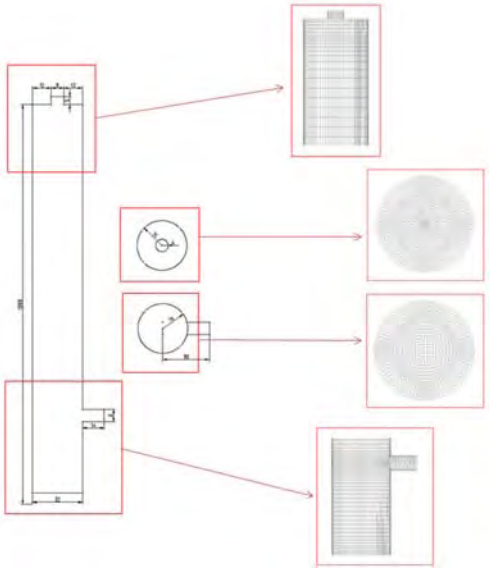
At the primary gas inlet, the superficial gas velocity, V_{sup}, was 0.71m/s. At the secondary gas inlet, the gas velocity and volume fraction were 0.05m/s and 0.6, respectively, and the particle volume fraction was 0.4. In order to permit all particles at the outlet back into the riser at the secondary gas inlet, a subroutine was implemented in the CFX code. At the outlet, atmospheric pressure was prescribed. At the walls, no-slip conditions were used for the solid phase as well as the gas phase.

The simulation results were computed through time-averaged distribution of flow variables. All the simulations were run for 7s of real time. To compute the granular temperature, solid-phase pressure and solid-phase bulk and shear viscosity must be programmed into the CFD codes due to the fact that the models used in this study were not presents in the CFX-10.

Figure 2 shows a comparison of the experimental results of Samuelsberg and Hjertager (1996) and the present numerical results to the solid radial velocity profiles for heights of 0.16, 0.32 and 0.48m in the riser section and superficial gas velocity, V_{sup}, of 0.71m/s at the primary gas inlet. Other simulations were performed to superficial gas velocities of 0.36 and 1.42m/s. All results presented the same trends.



(a)



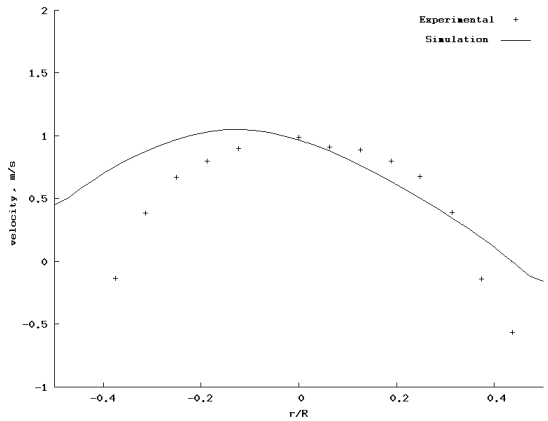
(b)

Figure 1 – (a) Geometry of Mathiesen *et al.* (2000). (b) Calculation domain and grid nodes

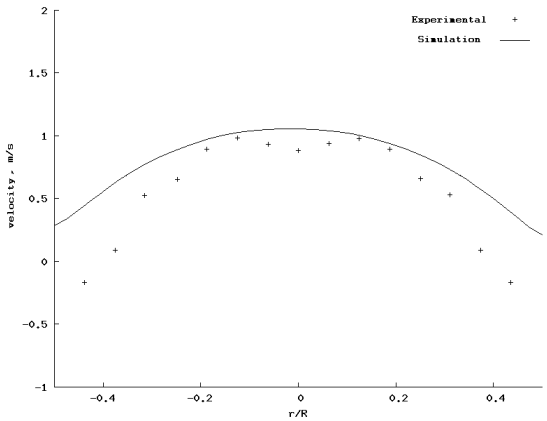
Table 1 – System properties

Gas density	1.185kg/m^3
Particle density	1600kg/m^3
Particle size	60μm
Gas viscosity	1.831x10^{-5}kg/m s
Maximum solids volume fraction	0.62
Particle-particle restitution coefficient	0.95

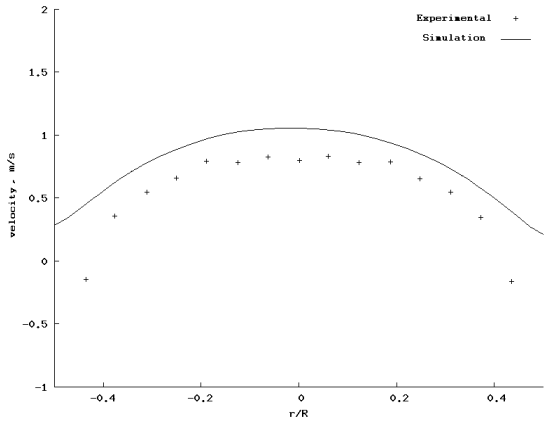
As can been seen in Figure 2 (b) and (c), the agreement is very good in the central region for all heights. The particles move upward in the central part of the riser and downward near the walls, a behavior well known from the literature, which is typical of core-annulus flow. However, in Figure 2 (a), for the height of 0.16m, the agreement between the curves differs significantly. These differences can probably be attributed to the region, at the height of 0.16m, being so close to the secondary inlet, causing large perturbations in the flow. In Figure 2, a significant difference can be observed in the wall region for all results compared. This result may indicate that the no-slip wall boundary condition for both phases is not correctly used when employing KTGF.



(a) Height of 0.16m



(b) Height of 0.32m



(c) Height of 0.48m

Figure 2 – A comparison of the experimental data of Samuelsberg and Hjertager (1996) and computed solid velocity profiles at different heights in the riser section and superficial gas velocity, V_{sup}, of 0.71m/s.

4. Conclusions

A three-dimensional two-phase flow model based on the kinetic theory of granular flow (KTGF) was used to predict the behavior of a gas-solid fluidized bed. The numerical results are compared against the experimental results of Samuelsberg and Hjertager (1996). The agreement is found to be satisfactory in the riser central region. However, in the wall region, the numerical results indicated a significant difference between all results compared.

Topic: Systematic methods and tools for managing the complexity.

Abstract

Almost everyone agrees that numerical models for simulating the microstructure of paper can bring tangible benefits to experiments. Nonetheless, after more than 20 years very few standard software packages at an affordable price were provided. This article explains the software implementation on key features of a three-dimensional random fiber deposition model. The approach was implemented as a prototype for a forthcoming MATLAB toolbox.

1 Introduction

Although theoretical paper models have existed in the literature for over two decades, most experimental research work encountered in the field of pulp and paper is mainly of empirical nature. One of the primary reasons that have hindered the generalized use of modeling in this area is the lack of easy understood models and available computational implementations.

Paper has a network structure of cellulosic fibers that lie roughly horizontal. It turns out that even for a thin material as paper it appears necessary to develop a three-dimensional (3D) structure model to be able to predict various properties consistent with experimental data (Alava and Niskanen, 2006). Simulation models which can grow networks of finite thickness are traced to the work of Niskanen and Alava (1994), who featured a 3D stacking of bendable fibers resembling real paper.

In this context, we aim to render the barrier to the use of modeling less binding by describing key building blocks of a MATLAB implementation for the KCL-PAKKA model (Nilsen et al., 1998). This is a simple 3D random sedimentation model to generate disordered fiber networks. We assume the reader has some familiarity with the MATLAB language.

In the next section we briefly review the basics for the sedimentation-like process. Besides the standard KCL-PAKKA we also discuss an extension of this model to incorporate a formation control parameter. Section 3 is the core of the paper. We present the prominent design features and discuss its MATLAB-specific implementation.

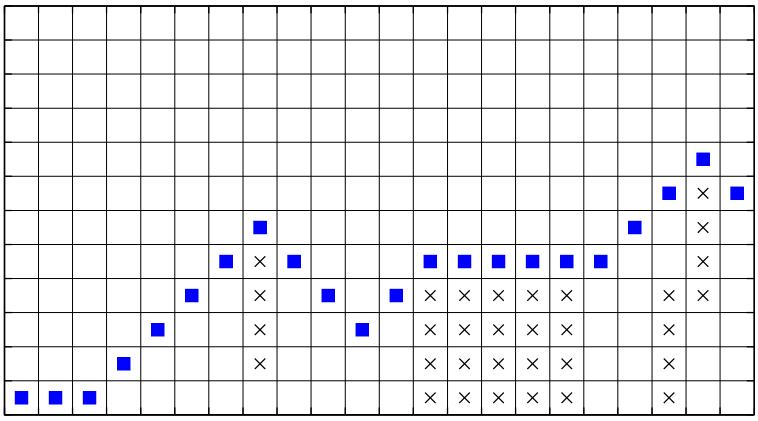

Figure 1: Bending mechanism of fiber generated by computational simulation. The crosses represent parts of previously deposited fibers and the squares denoting the bottom layer of the bending fiber. Bending flexibility $F = 1$.

2 Brief description of the handsheet formation model

To form a paper web, *flexible* straight fibers are laid down, one at a time, onto a flat substrate. Fibers are positioned and oriented at random in the in-plane (x and y) directions and placed parallel to the substrate on top of the underlying network. Thereafter the parts of the fiber that do not touch the network beneath them undergo bending in the vertical direction (or z direction) such that they either do contact with previous adjacent fibers or the largest deflection allowed by the bending stiffness of fibers is reached. In the latter case, free spaces arise between the fibers in the thickness direction because their stiffness prevents them from adjusting to the top surface roughness.

Flexing rule. Space is discretized into a Cartesian *uniform* grid of cells so that each fiber in the model is represented by a single vertical planar strip one cell wide and thickness of m vertical cells. Any two nearest neighboring cells on the fiber can make at most the maximum F vertical lattice steps allowed. We remark that this result depends only on the behavior of the bottom surface layer. It may be written as:

$$|z_{\mathrm{B}}(j) - z_{\mathrm{B}}(j')| \leq F,$$

where $z_{\mathrm{B}}(j)$ and $z_{\mathrm{B}}(j')$ are the elevations of two nearest neighbor cells j and j' covered by the surface bottom of a fiber and F can be any positive integer $\leq m$. Figure 1 shows what the deformed fibers look like in 2D.

Fiber interactions. The tendency of fibers in the suspension to concentrate around drainage sinks (those parts of the deposit that have less fibers per unit area) leads to a smoothing mechanism of a paper sheet. This effect is simulated by the particle deposition rule of Provatas and Uesaka (2003) which works over the *rejection model* introduced by Provatas et al. (2000). The operation works as follows: A candidate fiber lands on a section of the web whose mean height is compared with a fraction of its counterpart of the entire paper. If the following condition is fulfilled, the attempt is always accepted:

$$h \leq \alpha H,$$

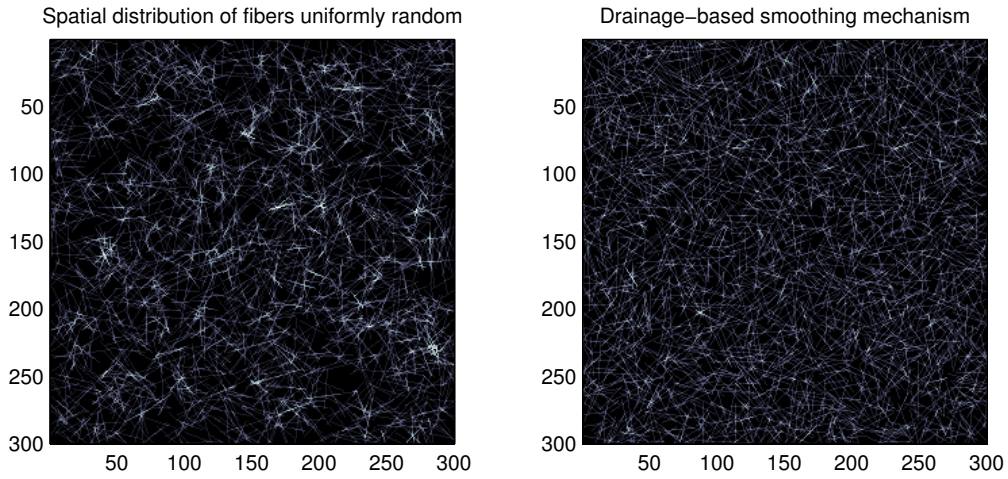

Figure 2: Simulated X-ray image of the (x,y) plane for paper handsheet as generated from the deposition rule, with formation control parameters set to $p = 1$, $\alpha = 1$ (left) and $p = 0.01$, $\alpha = 0.94$ (right).

where h is the average thickness of the paper over the projected area of the trial fiber, $0 \leq \alpha \leq 1$ is a constant, and H is the average thickness of the entire paper. Otherwise, the attempt is accepted only with a probability $0 \leq p \leq 1$, called the *acceptance probability*.

In the limit $p = 1$ produces uniformly random networks for all values of α. However, for $p \to 0$ the model tend to enhance mass density uniformity by favoring deposition into valleys within the web. Two configurations of fibers are shown in Figure 2.

3 Some implementation aspects

This section outlines the most essential implementation aspects. We list the relevant code and present a brief walkthrough. We restrict ourselves to only one type of fiber for the sake of simplicity and emphasize that the code is purely illustrative.

To summarize, our generation process of a 3D fiber network consists of the following steps:

1. Generation of a fiber in the in-plane directions.
2. Testing particle deposition rule. If the fiber is not accepted, the generation trial is repeated.
3. Extraction of the out-of-plane slice from the 3D network where the bending procedure occurs.
4. Fiber bending simulation for the bottom surface.
5. Filling up the remaining $m-1$ cell layers and then the 3D network is updated.

Generation of a fiber. Each straight fiber is built by randomly placing the center within the boundaries of a flat surface represented by the rectangle $[0,L_x] \times [0,L_y]$ such that both position and orientation are uniformly distributed. This corresponds to the case of laboratory handsheets. Fibers length is characterized by a Poisson distribution following Provatas and Uesaka (2003). After this the fiber is discretized to a chain of square cells of size w onto a discrete lattice $[1,N_x] \times [1,N_y]$. They are defined by the *Bresenham's line drawing algorithm* (Agoston, 2005, pp. 38–40). Fiber length in lattice units is a multiple of w. Parts of fibers that exceeds the lattice limits are cut. In MATLAB this can be done with

```
XMIN = 1; YMIN = 1; XMAX = Nx; YMAX = Ny;
midpoint = unifrnd([0 0], [Lx Ly], 1, 2);
orientation = unifrnd(-1, 1, 1, 2);
orientation = orientation / norm(orientation);
half_fiber_length = poissrnd(mean_fiber_length) / 2;
startPt = midpoint - half_fiber_length*orientation; % Start point of segment.
endPt = midpoint + half_fiber_length*orientation;   % End point of segment.
% Transforming from continuous to discrete coordinates.
startPt = floor(startPt.*[(Nx-1)/Lx (Ny-1)/Ly] + 1);
endPt = floor(endPt.*[(Nx-1)/Lx (Ny-1)/Ly] + 1);
% Draw the discrete fiber segment using Bresenham algorithm.
[fiber_xcoord, fiber_ycoord] = bresline(startPt, endPt);
% Restrict the fiber segment to the rectangle [1,Nx] x [1,Ny].
clip = fiber_xcoord < XMIN | fiber_xcoord > XMAX | ...
       fiber_ycoord < YMIN | fiber_ycoord > YMAX;
fiber_xcoord(clip) = [];
fiber_ycoord(clip) = [];
```

Extracting an out-of-plane slice from the 3D network. The region under consideration is divided into $N_x \times N_y \times N_z$ cells in the form of a square parallelepiped. The array web of dimension N_z-by-N_x-by-N_y is used to store the 3D grid of discrete locations. Once the (x,y) coordinates of the fiber have been obtained our task is to extract the two-dimensional vertical slice in the volume web at the points in the column vectors fib_xcoord and fib_ycoord. The sedimenting fiber bends around structures along this planar surface. The following is one possible way to do this:

```
z_extent = firstVPos:lastVPos;
height = length(z_extent);
width = length(fib_xcoord);
X = repmat(fiber_xcoord, height, 1);
Y = repmat(fiber_ycoord, height, 1);
Z = repmat(z_extent', 1, width);
web_idx = sub2ind([Nz Nx Ny], Z, X, Y);
bending_slice = web(web_idx);
```

This will generate the (i,j,k) subscripts of web comprising the particular slice. We then use the function sub2ind to convert to one-dimensional subscripting and this can be used to index into web.

Fiber bending simulated using a cellular automata framework. The spatial discretization allow us to exploit the potential of *cellular automata* (see the book by Schiff, 2008). A cellular automaton is a spatial discrete time model. Each cell can exist in different states chosen from a finite set. At each time step each cell changes its state based on a set of rules or *transition functions* that represent the allowable physics of the phenomena.

The discrete space for the automaton maps onto the bending plane and is represented in the matrix bending_slice. For each cell, (i,j), at time t there are three states which represent the presence or absence of fiber particles, namely:

Moving Deforming particle covers cell.

Idle Stopped particle covers cell.

Empty The cell is unoccupied.

As time goes on, the new state of each cell $s_{t+1}(i,j)$ is then updated according to the following rules:

$$\begin{aligned} s_{t+1}(i,j) = \text{idleCell} \leftarrow s_t(i,j) = \text{movingCell} \wedge (s_t(i-F, j-1) = \text{idleCell} \vee \\ s_t(i+1,j) \neq \text{emptyCell} \vee \\ s_t(i-F, j+1) = \text{idleCell}) \end{aligned}$$

$$\left.\begin{aligned} s_{t+1}(i,j) = \text{emptyCell} \\ s_{t+1}(i+1,j) = \text{movingCell} \end{aligned}\right\} \leftarrow s_t(i,j) = \text{movingCell} \wedge \neg (s_t(i-F, j-1) = \text{idleCell} \vee$$
$$s_t(i+1,j) \neq \text{emptyCell} \vee$$
$$s_t(i-F, j+1) = \text{idleCell})$$

$$s_{t+1}(i,j) = \text{idleCell} \leftarrow s_t(i,j) = \text{idleCell}$$
$$s_{t+1}(i,j) = \text{emptyCell} \leftarrow s_t(i,j) = \text{emptyCell} \wedge (s_t(i-1,j) = \text{emptyCell} \vee s_t(i-1,j) = \text{idleCell})$$

where i and j are the row and column indices and the negation of a given statement P is denoted by $\neg P$. Via the preceding rules, particles can move only in the downward (increasing time) direction at most one cell at each time step t, so that the cell states are updated *asynchronously* by a line-by-line sweep of each row sequentially. An example of code that would implement this behavior might look like this:

```
bending_slice = ...
    [repmat(EMPTY,height,1) bending_slice repmat(EMPTY,height,1)];
stop = false(1, width+2);
run = [false true(1, width) false];
j = 2:width+1;
for i = startInd:height-1
    stop(j) = bending_slice(i-F, j-1) == IDLE | ...
                bending_slice(i+1, j) ~= EMPTY | ...
              bending_slice(i-F, j+1) == IDLE;
    bending_slice(i, run & stop) = IDLE;
    run = run & ~stop;
    if all(~run), break, end % Fiber bending stops.
    bending_slice(i, run) = EMPTY
    bending_slice(i+1, run) = MOVING;
end
bending_slice( end, bending_slice(end, :) == MOVING ) = IDLE;
bending_slice(:, [1 end]) = [];
```

In the first part of the code the lattice is augmented by a column vector of fictitious cells having the pre-assigned value EMPTY at the extreme left and right sides, so that the corresponding neighborhood is completed. The loop, **for** i = startInd:height−1, drives the line-by-line sweep. We use logical vector run & stop to pick out those js at which particles moving terminate given the i current value. We then compute the vector run & ~stop whose true elements specify the moving particles left. On leaving the **for** loop we restore the lattice of cells to the original dimensions in the assignment bending_slice (:, [1 **end**]) = [];.

Copying the plane back into the 3D network. Finally, having defined the vertical coordinates z_j describing the location of the bottom surface, it is time to filling up the remaining $m-1$ cell layers stacked one on top of the other through each point of the fiber. All we need now is to carry out the updating of the 3D network. This can be done by

```
zPos = find(bending_slice == IDLE);
bottom_idx = sub2ind([height width], zPos, 1:width);
stack_idx = bsxfun(@minus, bottom_idx, 0:m-1);
bending_slice(stack_idx) = fiberID;
web(web_idx) = bending_slice;
```

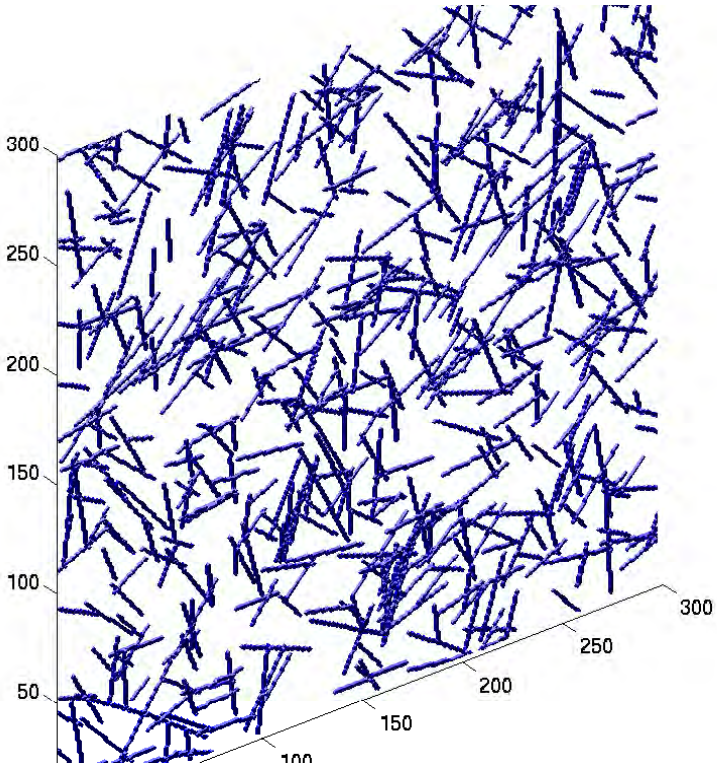

Figure 3: Simulated 3D fiber network.

Figure 3 shows an example of a 3D fiber network constructed with the prototype implementation.

4 Conclusion

There are huge gains to be had by simulating paper webs. This article is intended to serve as an illustration of the cellular automata framework to your coding work. We choose to use cellular automata since through the use of interactive components parts the high-level bending behavior *emerges* as a result of rules fairly straightforward to implement.

Keywords: Venturi, Multiphase flow, CFD
Topic: Advancing the chemical and biological engineering fundamentals.

Abstract

Venturi scrubbers are efficient and effective devices for gas cleaning. In addition, they may be used for cooling and humidification processes, which are major requirements in some industries.

Using computational fluid dynamics techniques, the multiphase flow behaviour of a venturi scrubber has been modelled. The simulations were carried out using Fluent, which is based in the finite volume method. The gas flow is simulated using the Eulerian approach solving the Navier-Stokes equations and a Lagrangian procedure has been taken describing the motion of the liquid droplets.

The results obtained have been validated with experimental work in a large scale venturi scrubber. Different air and liquid flow rates were tested. Very good agreement has been obtained, making this approach very useful in testing new geometries.

1 Introduction

Venturi scrubbers are very attractive devices for gas cleaning in industrial environments and are applicable from small scale textile plants up to large scale power plants. They combine a simple and robust construction with high efficiency for small, micron size, particles. Furthermore, they can be used for other purposes such as gas absorption and cooling.

They have been extensively studied in order to foster their understanding and modelling. The flow of gas and water in a venturi scrubber can be described as annular two-phase flow with further complexities due to the venturi geometry. Different models have been proposed in the literature and they range from simple correlations to more complex models (Azzopardi et al., 1991; Cruz et al., 1997; Ananthanarayanan and Viswanathan, 1999, Pak and Chang, 2006).

Pressure drop is a major parameter in assessing the performance of venturi scrubbers as the energy costs associated with gas pumping are the main drawback of these systems. It has been observed that an improvement in the efficiency of the equipment is always related to this parameter (Gamisans et al., 2002).

In this study, a computational fluid dynamics (CFD) model for the flow in a large-scale venturi scrubber has been developed using the Fluent software. This is based upon the finite volume method to solve the conservation equations. The effect of the turbulence models on pressure drop and axial velocity is analyzed. Predictions concerning the local and overall pressure drop are compared with data from an experimental facility for a wide range of operating conditions. An Eulerian-Lagrangian approach has been taken in simulating the two-phase flow.

2 CFD Model

Because of the geometry the two-phase flow inside the venturi is a very complex one. The gas entering the venturi accelerates in the convergent section. It reaches the higher pressure drop at the end of the throat and the pressure recovery in the diffuser must take into account the gas boundary layer growth.

The water is injected upstream of the convergence section by a set of a set of radial spray nozzles equally distributed around the venturi perimeter. The liquid jet penetrates into the gas core and is atomized into drops of varying size by the high velocity air stream.

In the present model, the gas is treated as a viscous incompressible, Newtonian fluid and the flow is considered turbulent. The loading ratio of the liquid droplets is very low and so, the discrete-phase model of Fluent is used to study the droplet transport.

An Eulerian (continuous-phase)-Lagrangian (discrete-phase) approach is employed in the present model. The droplet trajectories are calculated using a Lagrangian formulation that includes the discrete phase inertia and hydrodynamic drag.

As both phases are at ambient conditions, there is no heat or mass transfer between the discrete and the continuous phases and the droplets are defined in the model as inert. The dispersion of droplets due to turbulence in the gas phase is predicted by using stochastic particle tracking. Fluent predicts the turbulent dispersion of particles by integrating the trajectory equations for individual particles, using the instantaneous fluid velocity along the particle path during integration.

2.1 Mathematical Model

The governing equations for the continuous phase are the continuity, the momentum and the turbulence equations. The mass conservation equation, often called the equation of continuity, is:

$$\frac{\partial u_i}{\partial x_j} = 0 \tag{1}$$

For the resolution of the velocity field, the Navier-Stokes equations are solved. These equations describe the momentum conservation:

$$\rho u_j \frac{\partial u_i}{\partial x_j} = -\frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j}\left[\mu\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3}\delta_{ij}\frac{\partial u_l}{\partial x_l}\right)\right] + \frac{\partial}{\partial x_j}\left(-\rho\overline{u_i' u_j'}\right) + S_D \tag{2}$$

where u_i is the air phase velocity components, p is the static pressure, ρ is the air density, μ is the air viscosity, $-\rho\overline{u_i' u_j'}$ is called the turbulent stresses and the last term represents the source terms due to the presence of particles/droplets.

Due to the importance and complexity of the turbulence flow, an appropriate turbulence model must be chosen. The turbulence kinetic energy, k, and its rate of dissipation, ε, are obtained from the following transport equations, based on the Renormalization Group (RNG) k-ε model:

$$\rho\frac{\partial}{\partial x_i}(k u_i) = \frac{\partial}{\partial x_j}\left[\alpha_k \mu_{eff}\frac{\partial k}{\partial x_j}\right] + G_k - \rho\varepsilon \tag{3}$$

$$\rho\frac{\partial}{\partial x_i}(\varepsilon u_i) = \frac{\partial}{\partial x_j}\left[\alpha_\varepsilon \mu_{eff}\frac{\partial \varepsilon}{\partial x_j}\right] + G_{1\varepsilon}\frac{\varepsilon}{k}G_k - C_{2\varepsilon}.\rho.\frac{\varepsilon^2}{k} - R_\varepsilon \tag{4}$$

In Fluent, the trajectories of a discrete phase particle (droplet) are predicted by integrating the force balance on the particle which is written in a Lagrangian reference frame, for the x-direction in Cartesian coordinates, as:

$$\frac{du_D}{dt} = F_D(u - u_D) + g_x \frac{\rho_D - \rho}{\rho_D} + F_x \tag{5}$$

where u_D is the particle (droplet) velocity and ρ_D is the droplet density. The first term in the right side of equation (5) accounts for the drag force and F_D is the drag force, given by:

$$F_D = \frac{18\mu}{\rho_D d_D^2} \frac{C_D \,\mathrm{Re}}{24} \tag{6}$$

where μ is the molecular viscosity of the fluid and d_D is the droplet diameter.

The second term in the right side of equation (5) accounts for the gravity effects and F_x includes additional forces such as thermophoretic force, Brownian force, Saffman's lift force which can be important only in certain circumstances. However, provided that the particles meet the condition that $\rho_D \geq \rho$, these two terms can be neglected.

2.2 Boundary conditions

The air velocity is used as the inlet condition, and an outflow condition is considered at the venturi outlet. Outflow boundary conditions are used to model flow exits where the details of the flow velocity and pressure are not known prior to the solution of the flow problem. They are appropriate where the exit flow is close to a fully developed condition, as the outflow boundary condition assumes a zero normal gradient for all flow variables except pressure.

The turbulence model requires parameters that estimate *k* and ε at the inlet and outlet. The turbulence intensity and the hydraulic diameter approach are used to specify *k* and ε at inlet and outlet of the venturi. The diameter of venturi is used as the hydraulic diameter and the turbulence intensity is predicted using the relation for fully developed flow (Fluent user's guide, 2005).

2.4 Solution Procedure

The SIMPLE (Semi-Implicit Method for Pressure-Linked Equations) algorithm is used by Fluent, to couple the momentum and continuity equations for the gas phase. In the momentum and turbulence equations discretization, the second order implicit method was applied.

Fluent solves the continuity and momentum equations in every control volume of the domain. The turbulence parameters are then calculated. Once convergence has been achieved, the particle trajectories are determined and after these calculations the continuous phase source terms are updated, in a two-way coupling approach.

3 Results

The experimental validation of these more complex models is always important but experimental data, in large-scale venturi scrubbers, are scarcely available in the literature.

A large scale cylindrical venturi was built for measuring the most relevant operating parameters for industrial applications and to provide a reliable experimental data base that can be used for model validation. The experimental measurements include: the pressure drop along the venturi (Silva et al., 2008a), the droplet size, measured by a laser diffraction based instrument (Silva et al., 2008b), and the performance of the venturi scrubber in the

collection of fine powder (Silva et al., 2007), for different operating parameters such as gas velocity and liquid flow rates. The liquid mass flows tested are from 0.013 to 0.075 kg/s and the throat gas velocity varied between 34 and 70 m/s.

The geometric details of the scrubber used in the present work are presented in Figure 1.

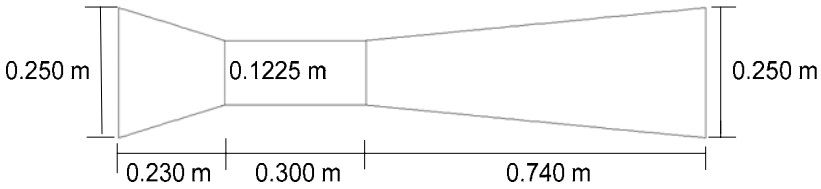

Figure 1 – Schematic of venturi scrubber used.

For the domain discretization, flow symmetry is assumed along the cross sections of the scrubber. Hence only one-fourth of the scrubber volume is modeled. The resulting grid is defined using a Hexahedral/Wedge Cooper mesh generation algorithm in Gambit. The 3D final mesh results in 15229 hexahedral elements (Figure 2).

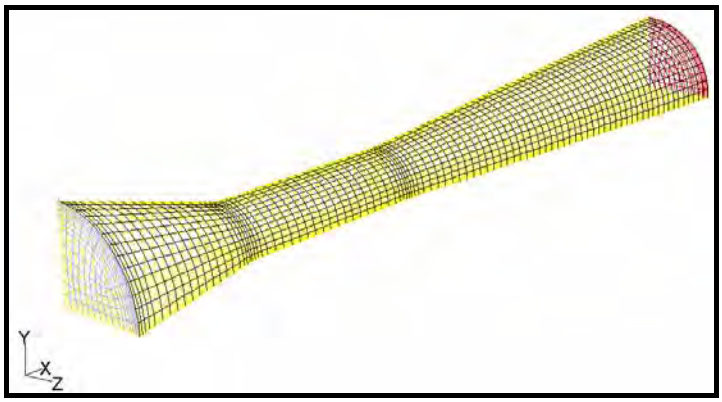

Figure 2 – Computational grid for the domain (Gambit).

In order to test the gas phase calculations, the various gas throat velocities (Vg) have been simulated. Convergence and grid independence of the results have been reached and Figure 3 shows the pressure drop along the venturi, relatively to that at the venturi inlet.

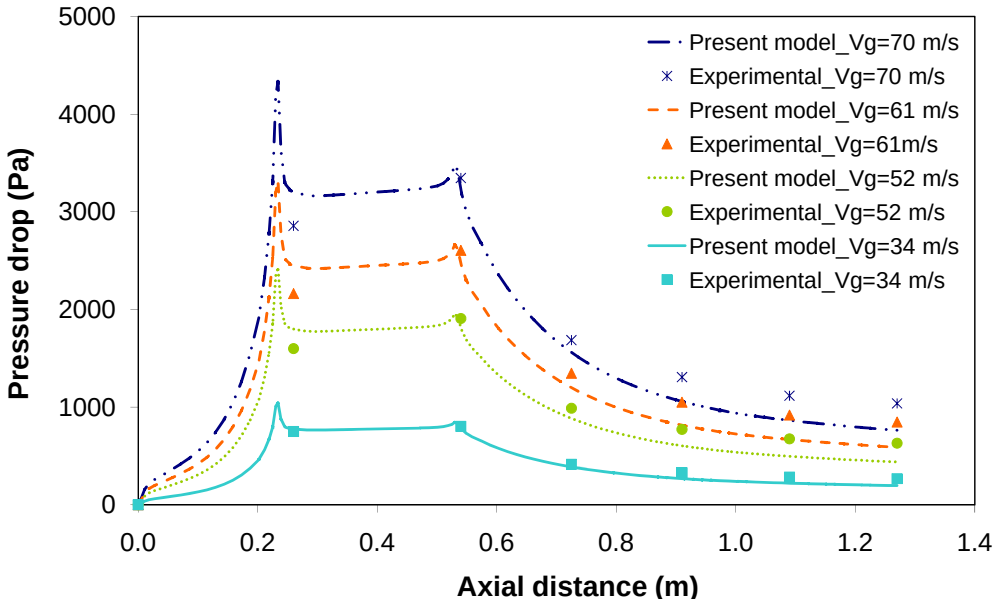

Figure 3 – Experimental and numerical single-phase pressure drop for various air velocities.

The sharp peaks in the predicted pressure drop values represent the losses at the sudden transitions between the throat and the converging and diverging sections. The experimental entrance of the throat, although some differences can be observed in this region.

These small discrepancies between the experimental data and the model simulations are more evident for higher velocities.

The effect of the dispersed phase was then simulated. The liquid mass flow rate was introduced through the spray nozzles at the venturi entrance. The droplet size distribution is within the range from 15 to 1504 μm for all the operating conditions simulated.

The data for a liquid mass flow rate of 0.038 kg/s and throat gas velocity of 70 m/s case are presented in Figure 4. The results for pressure drop along the venturi geometry show a very good agreement with the experimental data.

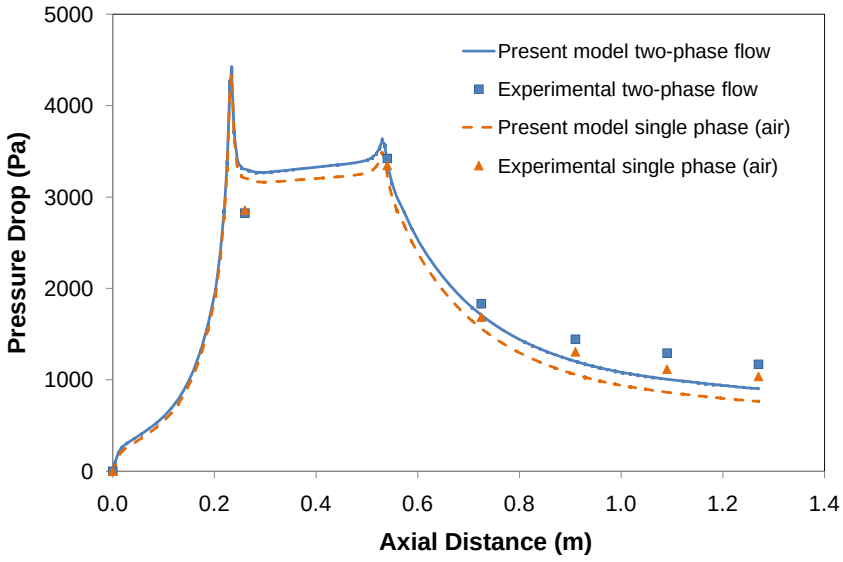

Figure 4 – Comparisons between experimental and predicted pressure drop along venturi.

The predicted pressure drop in the converging section, in the converging and throat sections and the total pressure drop are plotted against the available experimental data on Figure 5. The results are very encouraging.

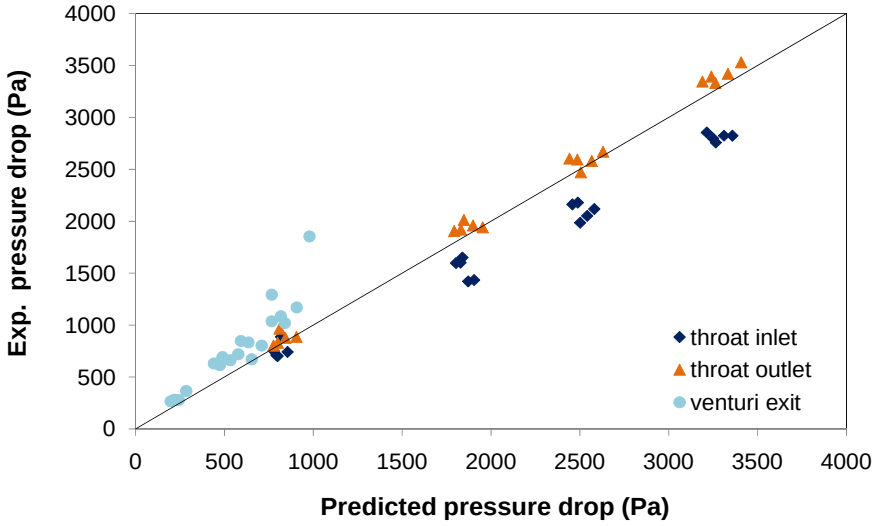

Figure 5 – Experimental versus numerical pressure drop results for the available data.

It can be observed that for the beginning of the throat the predicted values are higher that the experimental ones. At the end of the venturi the opposite behavior is observed, that means the numerical model predicts higher pressure recovery than the experimental tests. At the end of the throat section, the numerical and experimental results present a perfect agreement.

4 Conclusions

A new two-phase model was developed to predict pressure drop along a venturi scrubber, using the CFD code Fluent. An Eulerian-Lagrangian approach was used and a liquid droplet distribution has been considered. The model was tested against experimental data and very good results have been obtained.
Annular flow features are not included in the present work which can explain some discrepancies. This study shows that CFD models could be useful on the optimization of venturi scrubbers configurations.

Topic: Systematic Methods and Tools for Managing the Complexity.

Abstract

A mathematical model with two different methods to represent the mass transfer in the biomass matrix, (series and parallel), is proposed to simulate a supercritical fluid extraction unit. The model is solved using the method of lines and finite differences with flow correction. Experimental data is fitted fairly well by both models with equivalent accuracy. Two operating regimes were detected in the selected experimental conditions: equilibrium and mass transfer controlled. The last one is more difficult to simulate, requiring specific mass transfer parameters for series and parallel alternatives, for its accurate representation.

1 Introduction

The supercritical fluid extraction (SFE) of natural compounds using CO_2 is a promising separation technique for the recovering of high added value products with minimum degradation, environmentally friendly solvents, and higher selectivities. An important related task is the SFE modelling and subsequent determination of the key parameters involved, in order to simulate the process and finally optimize the interested operating conditions. This work focus on the modeling of SFE of grape seed oil, and the numerical solution of the corresponding differential equations. The model comprehends a set of coupled material balances distributed into three control volumes: one mass balance to the fluid phase (extractor bed), another one to the freely available oil in the seed, and a third mass balance to the tied oil existent inside the core of the seed. Several authors propose different mechanisms for the transport kinetic in the solid particle, as mass transfer in parallel or in series (Marrone *et al.*, 1998; Sovová, 2005). Both approaches are analyzed and compared. The solutions obtained are compared with experimental data provided in terms of extraction curves, i.e. extraction yield *versus* time. The concentration wave fronts inside the extractor are compared and computation time reported.

2 Model Description

The matematical modelling of a SFE unit to carry out the extraction of natural products with supercritical (SC) CO_2 has been an important target of study in the last two decades. Frequently, the column is considered isothermal, and both pressure drop and axial dispersion are neglected in the moving phase while, in the biomass matrix, several approaches have been used to describe the interaction between the SC fluid and the solid particle containing the natural product to be extracted. Several alternatives have been considered for these interactions, most of them altering the type of equilibrium relationships and particle modelling (Sovová, 2005). While the mass balance to the moving phase is well understood, the hardest task has been an amainable representation of the biomass matrix. This is a complex region structured on cavity arrays where in their interior are placed the oil bearing units

* Corresponding author. Tel +351-234 401 549. E-mail:fsilva@ua.pt

(Sineiro *et al.*, 1998). Figure 1 shows a simplified preview of the extraction column. At the grain scale, all its internal details were smoothed in two regions, accessible (η fraction) and non direct accessible ($1-\eta$ fraction). This concept was introduced to take into account some biological morphology (Sovová, 1994). Looking to the main SFE unit, it can be envisioned as composed by two main regions: a) a moving phase occupying the bulk void fraction ε, where the SC solvent is collecting the natural products from biomass; b) a fixed biomass composed region, occuping the void fraction $1-\varepsilon$, where the oil is initially retained in two types of regions: b.1) An oil free region, occuping the particle volume fraction η, where the solute is extracted with minor transfer resistance; b.2) an oil non-free zone, occuping the particle volume fraction $1-\eta$, where the solute is obtained with higher mass transfer resistance or even inaccessible.

Figure 1, shows schematically the extraction column identifying each zone and two plausible mass transfer options tagged as Series (Sovová, 2005) and Parallel (Marrone *et. al.*, 1998). A particle model is considered a "series model" due to the form how the mass transits from the non-free oil from inside seed cavities or tied to the internal structure to the free oil region of the seed, broken cavities or pore particles, and from here to the external fluid. Another way to model this system is by assuming that both free and non-free regions are exposed directly and simultaneously to mass transfer to the moving fluid but at different rates. Based on the control volumes of the extractor unit depicted in Figure 1 two mathematical models have been implemented, one for series and another one for parallel mass transfer. Table 1 presents the set of partial diferential equations, initial and boundary conditions which conforms the models.

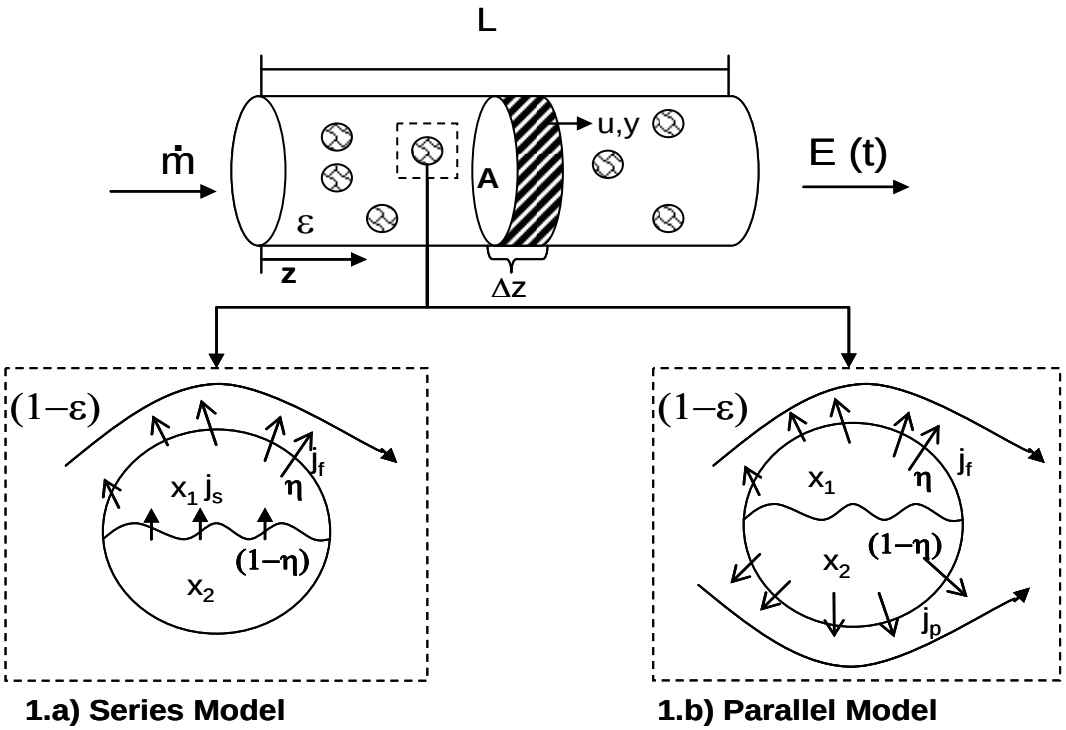

Figure 1: Scheme of the extractor column. Main control volumes used, and mass tranfer options considered: a) Flowing phase, y, occupying the void volume fraction, ε; b) biomass fraction, $(1-\varepsilon)$; where two zones are identified: free available oil, x_1; non-free oil, x_2.

Two mass transfer model options are represented in terms of: **1.a)** $j_f / \bar{j}_s$ for the series model case, and **1.b)** $j_f / \bar{j}_p$ with parallel model alternative.

A set of partial differential equations of the hyperbolic type results, which can be solved by classical numerical techniques: the Method of Lines (Shiesser, 1994) and Method of Characteristics (Acrivos, 1956; Aris and Amundson, 1973; Perrut et al., 1997). In this work, the method of lines was adopted with axial spatial coordinate discretization using upwind finite differences. Additionally, the library due to Shampine (2005) is used for solving the same model, based on central finite differences with flux correction, a variant of Lax-Wendroff scheme with a non-linear filter (SLxW), which is a versatile and specialized numerical library for hyperbolic systems of equations. All these libraries and routines are implemented in Matlab. Single extraction curves were obtained numerically spending between 2 to 6 CPU minutes, with 50 segments in the axial coordinate, running in Pentium IV 3Ghz computers.

3 Extraction Curves

The extraction curve is obtained from experimental runs by registering the mass flow of solvent fed, $\dot{m}$, normally constant, and the natural product retired from the column as a function of time. From the model, it can be readily calculated as $E(t) = \dot{m}\int_0^t y(L)dt$.

Table 1: SFE mathematical model considering two type of particle mass transfer models in alternatives.

	Mass Balances	Initial and Boundary Conditions
	Particle Series Model	
Free Oil Region	$\eta\rho_s \frac{\partial \bar{x}_1}{\partial t} = j_s - \bar{j}_f$	$\bar{x}_1(0) = x_{1,o}$
Non-Free Oil Region	$(1-\eta)\rho_s \frac{\partial \bar{\bar{x}}_2}{\partial t} = -\bar{j}_s$	$\bar{\bar{x}}_2(0) = x_{2,o} \approx x_u$
	Particle Parallel Model	
Free Oil Region	$\eta\rho_s \frac{\partial \bar{x}_1}{\partial t} = -j_f$	$\bar{\bar{x}}_1(0) = x_{1,o}$
Non-Free Oil Region	$(1-\eta)\rho_s \frac{\partial \bar{x}_2}{\partial t} = -\bar{j}_p$	$\bar{\bar{x}}_2(0) = x_{2,o} \approx x_u$
	Mass balance in Moving phase	
Moving phase	$\varepsilon\rho_f \frac{\partial y}{\partial t} = -u\rho_f \frac{\partial y}{\partial z} + (1-\varepsilon)(j_f + \bar{j}_p)$	$y(0,z) = y_o$ $y(t,0) = 0$
	Equilibrium, mass transfer, initial closure restriction and extraction curve	
Equilibrium	$y^*(\bar{x}_1) = y_s(T,P), \bar{x}_1 > x_t$ $y^*(\bar{x}_1) = K(T,P)\bar{x}_1, \bar{x}_1 \le x_t; Kx_t < y_s$	
Mass tranfer	$j_f = \rho_f k_f a_f (y^*(\bar{x}_1) - y))$ $\bar{j}_s = \rho_s k_s a_s (\bar{\bar{x}}_2 - \bar{x}_1)$ $\bar{j}_p = \rho_f k_s a_s (y^*(\bar{\bar{x}}_2) - y)$	

Initial closure restriction	$(1-\varepsilon)\rho_s x_u = \varepsilon\rho_f y_0 + (1-\varepsilon)\rho_s(\eta x_{1,0} + (1-\eta)x_{2,0})$
Extraction Curve	$E(t) = \dot{m}\int_0^t y(L)dt$

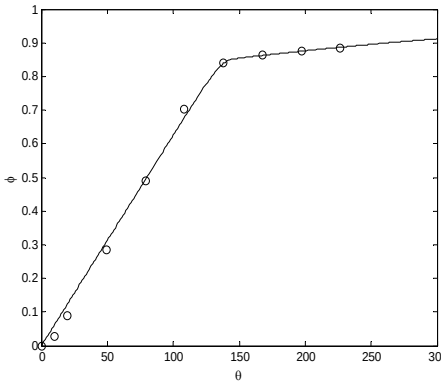

Figure 2: A dimensionless extraction curve fitted to the experimental data using the series model using upwind differences. Experimental data is from an oil grape seed extraction operating at 200 bar, 40ºC.

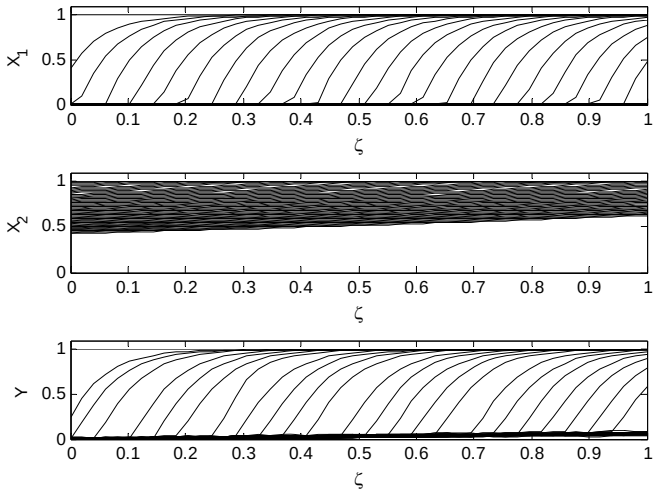

Figure 3: Axial profiles predicted in the interior of a SFE unit as a function of dimensionless time, θ, in intervals of $\Delta\theta = 6$, for dimensionless free (X_1), non-free (X_2) and solute concentration in the solvent, (Y).

In Figure 2 it is shown an experimental dimensionless extraction curve, $\Phi(\theta) = \dfrac{E(t)}{\text{Total extractable oil}}$, against dimensionless time, $\theta = \dfrac{t}{\tau}$, fitted with the mass transfer particle model and model parameters: $\varepsilon = 0.22$, $\eta = 0.796$, $x_u = 0.149$ kg/kg, $x_t = 0$ kg/kg, $x_{1,0} = 0.148$kg/kg, $y_0 \approx y_s = 0.0027$, $\tau =$,122s, $u = 0.033$ cm/s, $k_f a_f = 0.03$ s^{-1}, $k_s a_s =$ 3.6 .10^{-6}s^{-1}, $\rho_s = 688$ kg/m^3, $\rho_f = 840$ kg/m^3. The experimental extraction curve is reproduced fairly well, showing clearly two behaviors, first an equilibrium controlled regime followed by a mass transfer controlled step, after 150 dimensionless units. Figure 3 shows the progress prediction with dimensionless time of axial concentration profiles in the interior of the column for the same case, in terms of non-dimension variables, $X_1 = \dfrac{x_1}{x_{1,0}}$, free oil, $X_2 = \dfrac{x_2}{x_{1,0}}$, non free oil and $Y = \dfrac{y}{y_o}$ solute concentration in solvent gas against the spatial coordinated, $\zeta = \dfrac{z}{L}$. The two mass transfer regimes are detected again in the moving fluid phase. At the beginning, the X_1 and Y waves run together, and at the end, the Y collapses at the bottom, defining the mass transfer controlled period, where the non free oil, represented by the X_2 is the main source of the natural product. Figure 4 and 5 compares

the extraction curve and the evolution of axial profiles obtained with three different numerical methods: upwind finite differences, tank series and smoothed Lax-Wendroff (SLxW). In the equilibrium regime, all extraction curves solutions are equivalent, showing differences in the last part which reveals to be more sensible to differences in the axial profiles predicted in the interior of extractor column. They are more dispersive in tank series and more abrupt with

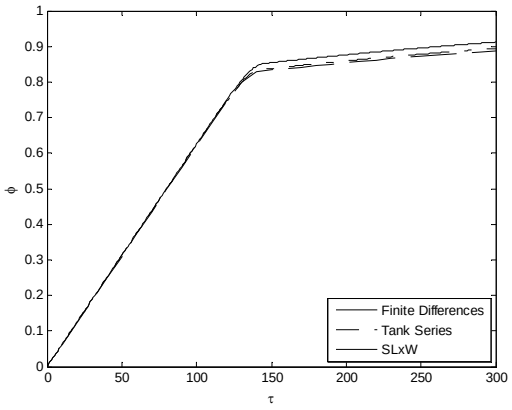

Figure 4: A dimensionless extraction curve obtained with different numerical methods: upwind finite differences, tank series (Sovová, 2005) and smoothed Lax-Wendroff (SLxW option, Shampine 2005). Modeling parameters are the same as Figure 2.

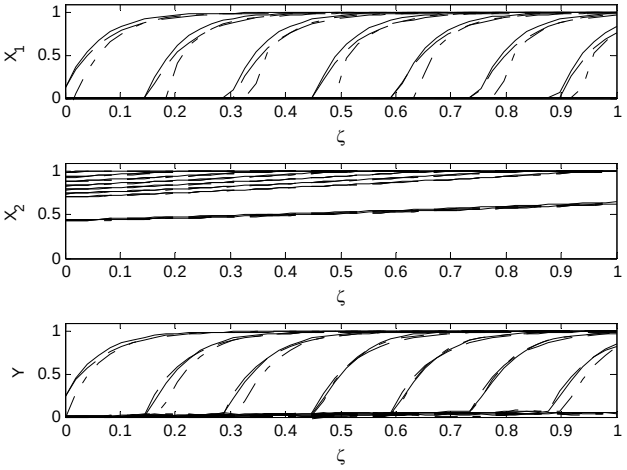

Figure 5: Dimensionless axial profiles with series model, using upwind finite differences (—), tank series (---) and SLxW (-.-) methods compared at $\theta =$ 10, 30, 50,…,130, 290 and 300.

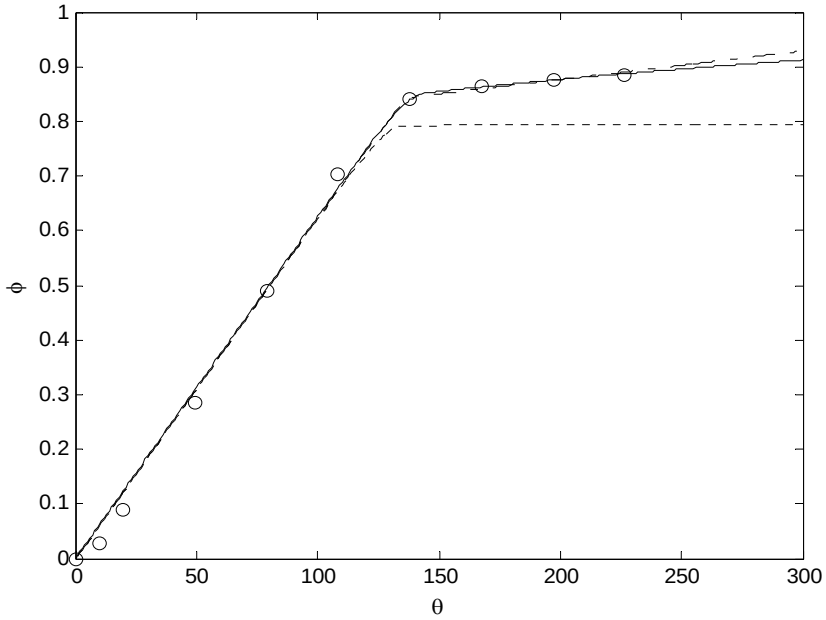

Figure 6: Extraction curve obtained with series model (—), parallel model with $k_f a_f$ =0.03s^{-1}, $k_s a_s$ = 3.6 .10^{-6}s^{-1} (---), and parallel fitted with $k_f a_f$ =0.048 s^{-1}, $k_s a_s$ = 2.7.10^{-4}s^{-1}(—·—).

the SLxW numerical option. Standard central differences of second order are not recommended because huge oscillations are obtained, damaging the axial profile and extraction curve simulation. Figure 6 compares the solutions obtained with the series model with the parallel option, using the same set of mass transfer parameters and those fitted with the parallel model. It is observed that the same set of parameters coming from the series model are not applicable to the parallel case, but this model can be easily fitted to the same experimental extraction curve, only modifying the mass transfer parameters.

4 Conclusions

A mathematical model with two alternatives for the particle mass transfer was proposed to simulate a SFE unit, solved using the method of lines with finite differences with flow correction. An experimental extraction curve is well fitted with both series and parallel mass transfer particle models only modifying the mass transfer coefficients. Two different operating regimes are detected upon the operating conditions of selected experimental data: and equilibrium and mass transfer controlled regimes. The most sensible zone of extraction curve was the mass transfer controlled regime at the end of the experiment, both to the numerical method used to discretize the axial coordinate in the column and the mass transfer approach used to represent the particle dynamic.

Topic: Systematic methods and tools for managing the complexity.

Abstract

The aim of this study is to perform a dynamic modelling and simulation of a Portuguese industrial integrated system in order to analyse the integration and feasibility of the different units, maximizing its efficiency and minimizing its environmental damage, and to study the effect of some operational and atmospheric conditions on the system.

For that purpose, a distributed dynamic model was built using *gPROMS 2.3.7* language for the integrated Process including a cogeneration system, a set of plate heat exchangers and a salt recrystallization process.

Thus it was analysed the effect of the heated brine spray system on the integrated process by considering a new three-dimensional dynamic mathematical model, which is based on the ballistic theory, and includes material and energy balances, and that allows to predict the spray system behaviour. It was studied its effect on the integrated process by comparing the global performance of the system with and without sprays. Due to air drift issues, quasi-random time daily profiles for the allowed operation of the spray system (on-off working time periods) were used. Using three distinctive atmospheric scenarios, several ponds sprays distributions schemes were analysed. A sensibility analysis of the salt production was considered by changing the fraction of the flow rate that enters in the ponds through taps and through sprays.

1 Introduction

The main goal of this study is to achieve the best operational conditions of an open air industrial integrated system including three processes, by exploiting different atmospheric scenarios, in order to maximize its global energy efficiency and to minimize the environmental impact, reducing the primary energy supply and the raw materials usage. This integrated system, located at Carriço, Pombal (Portugal), includes the following three separated processes: a natural gas storage built inside salt caverns owned by Transgás, a gas turbine cogeneration system owned by Galp Power, and a salt recrystallization process owned by Renoeste. The integration of these three independent units, improves the global system efficiency (Moita et al., 2004).

2 Dynamic modelling and simulation of the integrated system

The model of the whole integrated process was built through algebraic and differential equations taking into account the phase equilibrium thermodynamics: solid, liquid and gas phases. The integrated system includes the cogeneration system, the five plate heat

* Corresponding author. Tel + 351-21-8417639. E-mail:henrimatos@ist.utl.pt

exchangers and the salt recrystallization process. This involves, mainly, a maximum of six recrystallization ponds, a feed tank and a collecting channel.

The plate heat exchangers (PHE) are the physical connecting link between the cogeneration system and the recrystallization process. The PHE set was included using its design equation and heat balances at both sides. The mass and heat balances are axially distributed providing the expected profile inside the ponds (30 elements). The salt saturation concentration depends on brine density and salt solubility values, which vary with brine temperature.

The water evaporation rate is a function of the salt concentration, of the temperature in the brine solution and of the atmospheric conditions (air temperature, humidity and wind velocity). Both for the water evaporation rate and for the convection energy loss it was considered the maximum value obtained between natural and forced convection (mixed laminar-turbulent flow), given the importance of accounting for natural convection, specially at lower wind velocities (Moita et al., 2006).

The thermal power (TP) values are given by the cogeneration system operation. The solar energy contribution absorbed through the brine in the recrystallization ponds is the diffuse part and a fraction of the direct solar energy, which is dependent on the brine pond level.

A new heated brine spray distribution system model was also accounted for, that is an extension of the model previously presented (Moita et al., 2005), in order to study its effect on the integrated system by dynamic simulation. So, for that purpose, a three-dimensional dynamic mathematical model for the hereinabove mentioned heated brine spray system was built (Moita et al., 2008). Two models were developed: one for a single drop and the other for the spray system. The single drop model, which is based on the ballistics theory and includes material and energy balances, allows for the calculation of the trajectory and velocity of the drop once catapulted from a nozzle, as well as its temperature, salt concentration, and volume during the flight. The spray system model accounts for the effect of all the drops hits, released from a single full-cone spray-nozzle, by considering a set of random defined drops, through statistical distributions.

Some global variables for the entire spray system are determined by accounting the results for each drop i obtained with the dynamic model herein developed. For instance, it is possible to calculate the total spray volume (V_{sp}) and brine mass ($M_{brine,sp}$) obtained by unit of brine volume sent to the nozzle:

$$V_{sp} = \frac{\sum V_{drop,i}}{\sum V_{drop,i}\Big|_{t=0}} \tag{1}$$

$$M_{brine,sp} = \frac{\sum m_{brine,i}}{\sum V_{drop,i}\Big|_{t=0}} \tag{2}$$

The mean spray temperature T_{sp} is calculated through an energy balance in which the effect of all falling drops is accounted for. The total water evaporated by unit volume of the entering brine ($M_{evap,sp}$), during the spraying time, is given by:

$$M_{evap,sp} = \frac{\sum \int M_{evap,i}\, dt}{\sum V_{drop,i}\Big|_{t=0}} \tag{3}$$

The global evaporative spray efficiency (E_{ff}), which considers the convection and radiation energy losses to the open air, is determined by:

$$E_{ff} = \frac{\sum \int E_{evap,i}\, dt}{\sum \int \left(E_{evap,i} + E_{conv,i} + E_{rad,i}\right) dt} \qquad (4)$$

Using this new model the effect of several variables on the spray system behaviour was analysed. Based on the simulated results, multi-linear correlations for the water evaporation rate ($M_{evap,sp}$) and for the mean spray temperature (T_{sp}) were determined as a function of the heated brine temperature, air humidity and temperature, wind velocity and nozzle height, for a given operating pressure.

The effect of the spray system is included in the integrated system model by considering spray material and energy balances, using the mentioned correlations. A maximum of ten sprays were considered in each pond entering through its length, that is, in the axial elements of the pond model (around 30% of the total length).

The whole integrated system was modelled through the general-purpose modelling, simulation and optimization tool gPROMS 2.3.7, of the Process System Enterprise, Ltd. A flow diagram illustrating the dynamic model structure implemented in this software is shown in Figure 1. There are five sub-models, including the algebraic and differential equations needed to describe each system. Some variables are used as connecting sub-models information, such as brine flow rate (Q), concentration (X), temperature (T) and density (ρ).

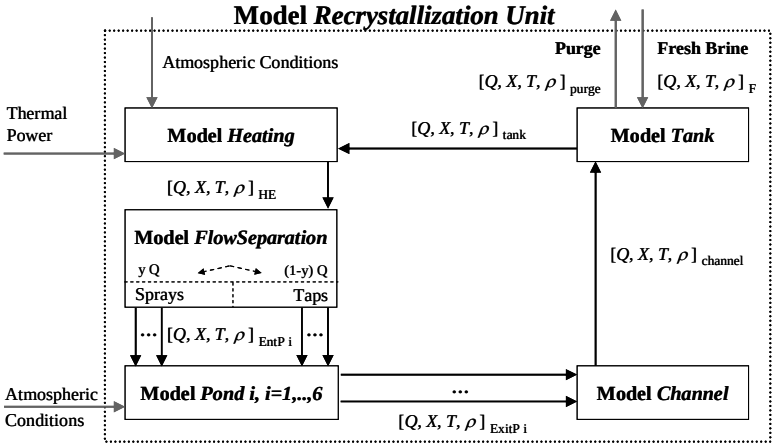

Figure 1. Structure of the dynamic model of the integrated process in gPROMS 2.3.7.

For this model the main state variables are: the number of ponds in service, the atmospheric conditions (wind velocity, air temperature and humidity), the fresh brine flow rate and concentration, the flow rate of the brine pumped into the plate heat exchangers, the thermal power profile and the solar energy input (Moita et al., 2005).

3 Influence of the brine spray system

The effect of the sprays system on the integrated process was analysed, by comparing its performance with and without sprays, using different operational and atmospheric scenarios.

Due to brine air drift issues for some wind directions the use of the spray system is prohibitive, and therefore on-off sprays working time periods must be defined. Using atmospheric data obtained from the industrial site, corresponding to 10 months (from August 2005 to May 2006), and by analysing the wind directions values, it was specified the allowed

time periods for the sprays operation. Then, for each month, it was calculated the mean hourly time percentage of allowed spray use, that is, by accounting the time intervals that sprays can be turned on in each hour of the day, and using all the data concerning that month. Using these mean hourly time percentages, it was calculated the total mean time percentage for the allowed operation of the sprays for the whole month. Based on these values, two scenarios were defined: a winter scenario, based on October to January total mean values; and a summer scenario, accounting monthly mean values of February to May, August and September. A third intermediate scenario was also considered (Moita et al., 2007).

For each scenario the global time percentage of spray use is constant. It was created a quasi-random time daily profile for the allowed operation of the sprays, which is repeated through the simulation time and respects the fixed global time percentage of spray use defined in each scenario (Table 1).

Table 1. Atmospheric conditions ($T_{air,}$ humidity, wind velocity V, solar energy E), global time percentage and random time daily profile of allowed sprays operation, for each scenario.

Scenario	**Winter**	**Intermediate**	**Summer**
Duration (h)	2830	1420	4250
Tair (ºC)	10	17	20
Humidity (%)	75	75	68
V (m/s)	1.3	3.0	2.3

nS = n hours with sprays Stopped (turned off);
mW = m hours with sprays Working.

Table 2 presents the salt production predicted by simulation, when sprays are turned on, using as a comparison the case of operation without sprays with 3 ponds in service (100 units of mass per year). The cogeneration system requires the water temperature T_2 within the operational interval of: 90± 1ºC. In order not to exceed this temperature it is not possible to work only with two ponds. The use of the spray system leads to a reduction of the ponds brine temperature, due to the cooling of the brine as the drops are sent from the nozzle to the open air. Therefore, the (v1 + v2) number of sprays can be useful since they allow operating with only two ponds, and still respect the mentioned temperature limits. For that purpose, it is required to use a 4+0, 8+0 and 10+0 ponds spray distributions in the winter, intermediate and summer scenarios, respectively. This operation scheme leads to a salt increase of almost 2%. Alternatively, the equivalent operation modes 2+2, 4+4 and 5+5 could be used.

Table 2. Salt production obtained without and with sprays for all the scenarios (um/year).

Scenario	**3P_(0+0+0)**	**2P_(0+0)**	**2P_(v1+v2)**
Winter	28.7	30.7	30.5 [a]
Intermediate	16.6	17.1	16.9 [b]
Summer	54.7	54.7	54.2 [c]
Total (u.m./year)	100.0	102.5	101.6

nP_(v_1+v_2+v_3) = n ponds, with v_1, v_2 and v_3 sprays entering in the first, second and third pond;
■ – Water temperature T_2 is higher than its upper limit (91ºC);
a: 2P_(4+0); b: 2P_(8+0); c: 2P_(10+0).

An operation scheme with 3 ponds, such as 3P_(2+0+0), could also be used. However, this leads to water temperatures values lower than its desirable lower limit. To avoid this, a brine flow rate distribution in the ponds and in the spray system should be used. Consider the heated brine flow rates distribution in the ponds and spray system illustrated in Figure 2, where y is the flow rate fraction sent to the sprays and x_n (n=2,3) is the fraction of the flow rate that was not sent to the sprays entering by taps in pond 2 or 3.

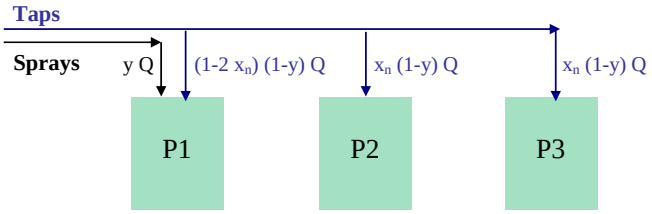

Figure 2. Brine flow rate distribution in the ponds and spray system.

Using as an example the intermediate scenario, and considering the mentioned 3P_(2+0+0) operation scheme, x_n values from 0.1 to 0.5 were considered. Reducing x_n to 0.1 increases the brine flow rate entering through the taps in the first pond, and decreases it in the two other ponds. When x_n is increased the opposite occurs, where a x_n value of 0.5 corresponds to an extreme situation in which the first pond only receives brine when the sprays are turned on, otherwise works as a “solar pond” (Figure 3).

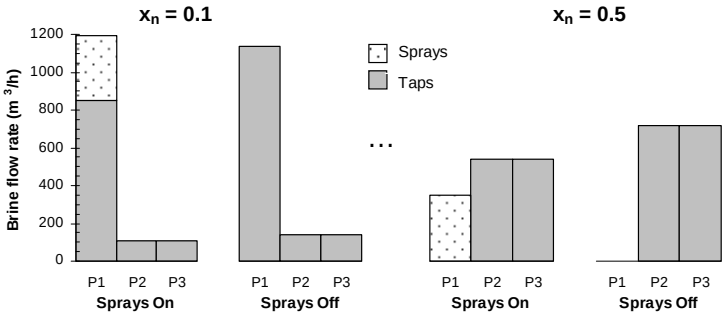

Figure 3. Flow rate distribution in (P_1, P_2, P_3) ponds with sprays on and off, considering x_n=0.1 and x_n=0.5.

Figure 4 shows the simulation results obtained from the sensibility analysis of the x_n value, namely, the hot and cold water cogeneration temperatures (T_2 and T_1), heated brine temperature and salt increase when compared to the base operation scheme (no sprays, 3 ponds).

In order to maintain the hot water temperature within the defined operational temperature interval, x_n should be between 0.15 and 0.2, or between 0.45 and 0.48, corresponding to a salt increase between 1.5 and 0.7%, or between 1.5 and 3.8%, respectively. Using the smaller values of x_n means large values of the brine flow rate in the first pond, while increasing x_n leads to a higher water temperature oscillation, due to the non-constant flow rate entering in the ponds.

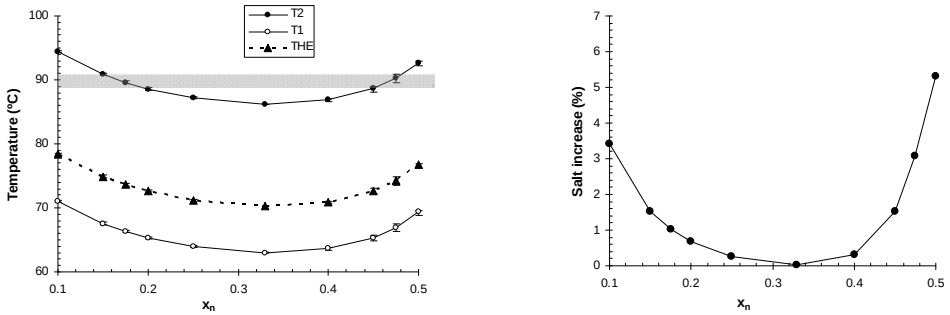

Figure 4. Hot and cold water temperatures (T_2, T_1), heated brine temperature (T_{HE}) and % of salt increase compared to the base operation (no sprays and 3 ponds), for x_n from 0.1 to 0.5; ■ – Hot water temperature (T_2) operational window.

4 Conclusions

The effect of the spray system on the integrated process was analysed through the use of a new dynamic mathematical model, by comparing its performance with and without the use of sprays. Due to air drift issues, on-off sprays working time periods were defined, by using quasi-random time daily profiles for the allowed spray operation. Using three characteristic atmospheric scenarios, several ponds sprays distributions were analysed. In order to respect the operational intervals of the temperature of the water circulating in the cogeneration system, and to work with only two ponds, the best option is to operate using two ponds with a (4+0), (8+0) and (10+0) spray system installed for the winter, intermediate and summer scenarios, respectively. This leads to a salt increase of almost 2%, if we compare with the base case of 3 ponds without sprays. Alternatively, a 3 ponds scheme with sprays can be used. For instance in the case of the intermediate atmospheric scenario, and considering that it operates with three ponds with two sprays in one of them, a heated brine flow rate ponds distribution should be implemented to increase the salt production up to 4%.

Topic: Systematic methods and tools for managing the complexity.

Abstract

The grape juice fermentation constitutes the core of the winemaking process. In this stage, complex physical, chemical and biological changes occur. Also, the presence of non-constant parameters and high non-linearities produce complex dynamic responses of the bioprocess. In this work, a non-isothermal phenomenological model for a batch alcoholic fermentation is proposed. The model predicts the main process state variables: viable cells, substrate (sugar) and ethanol concentrations, carbon dioxide released, and the bioreactor temperature. It is based on the model developed by Scaglia *et al.* (2008) which is excellent for isothermal fermentations. In this case, the main model objective has been posed on temperature, due to its control is critical to produce high quality wines and to reduce the winery cooling requirements. The model combines mass and energy balances coupled by the Arrhenius equation that describes the temperature influence on the cell growth rate. Due to the temperature inside the bioreactor must be maintained at 23±1 ºC to avoid the quality product decrease, a wide performance analysis with the model proposed was carried out. The obtained results from simulation show acceptable agreement with own experimental and published data. Therefore, the acceptable model performance will allow its application in advanced optimization and control strategies.

1 Introduction

High-quality wines are the market segment that offers the best advantages for wine production in Cuyo (Argentina). Usually, fermenters are operated in batch mode with limited control. Therefore, a strict process monitoring and control in winemaking is required (Vallejo *et al.*, 2005; Ortiz *et al.*, 2006). Also, some of the selected strains possess killer properties, which represent a guarantee for their implantation in the fermentation (Zagorc *et al.,* 2001).

The alcoholic fermentation in winemaking is characterized by complex physical, chemical and biological changes, the presence of non-constant parameters and high non-linearities, which produce complex dynamic responses of the bioprocess and determine the final quality of wine. Although many of these problems have been widely studied (Boulton *et al.*, 1996; Fleet, 1993), it still exist several that need to be solved.

In this work, a non-isothermal model for a batch alcoholic fermentation is presented. The model couple mass and energy balances predicting the behavior of the main state process variables: viable cells, substrate (sugar) and ethanol concentrations, carbon dioxide released, and the bioreactor temperature. The proposed model is based on the one developed by Scaglia *et al.* (2008), that possesses a good performance for isothermal fermentations. In this case, the main model objective has been posed on temperature, due to

* Corresponding author. E-mail: rortiz@unsj.edu.ar

its control is critical to produce fine wines with constant quality and to reduce the winery cooling requirements (Aballay *et al.*, 2006).

The proposed non-isothermal kinetic model consists of a set of ordinary differential equations (ODE) for the balances mentioned, including the heat transferred between the reactor and its cooling jacket. Balances have been coupled by means of the Arrhenius equation which describes the temperature influence on the cell growth rate (Aballay *et al.*, 2006; Phisalaphong *et al.*, 2006).

Kinetic parameters were adjusted using experimental data obtained from anaerobic lab-scale cultures of *Saccharomyces cerevisiae* (killer), and/or *Candida cantarelli* yeasts in Syrah must (grape juice) (Toro and Vazquez, 2002). In the case of the specific parameters in Arrhenius expression, they were adjusted by the least-square method (Aballay *et al.*, 2006).

Due to in practice, the temperature in the bioreactor must be maintained constant at 23±1 ºC to avoid the quality product decrease, a performance analysis by using the dynamic model developed was carried out. The most frequently found disturbances in real plants are applied on the main manipulated process variable, and the corresponding responses of the state process variables considered are showed.

Results from the proposed model simulation and its performance analysis are shown. They report acceptable agreement with own experimental and published data, predicting fermentation evolution without appreciable delays what allows to take proper control actions on the process.

The paper is organized as follow. First, the non-isothermal kinetic modeling of the bioprocess from a previously developed isothermal model is presented. Second, the experimental data from laboratory tests and, the simulation results are exhibited. Third, the model performance analysis is developed. Fourth, a discussion about the application of the obtained model in advanced optimization and control strategies and conclusions are exposed.

2 Modelling

The reductive metabolic pathway characterizes the yeast population growth in anaerobic conditions as: $S \rightarrow X + P + CO_2$

In this equation, X, S, P and CO_2 correspond to viable cells, carbon source (glucose and fructose) and ethanol concentrations, and carbonic dioxide released [kg m^{-3}], respectively.

The formation ethanol reaction from glucose is: $C_6H_{12}O_6 \rightarrow 2CH_3CH_2OH + 2CO_2$ (1)

The metabolite accumulation in the extra cellular medium has been modelled by a set of ODE based on mass balances on X, S, P and CO2 like in the isothermal model of Scaglia et al. (2008), which can be seen for further details. All the mentioned variables depend on cells concentration evolution in time t [h] and the kinetics for cell growth is mainly subject to μ_m,

$$\left\{\frac{dX}{dt}, \frac{dS}{dt}, \frac{dCO_2}{dt} and\ \frac{dP}{dt}\right\} = f(X), \text{ and } \frac{dX}{dt} = f(\mu_m) \quad (2)$$

The non-isothermal kinetic model proposed here is constituted by the previous mass balances and the energy balance in the reactor and its cooling jacket. These balances were coupled by means of Arrhenius equation that describes the main influence of the temperature on cell growth rate (Aballay *et al.*, 2006; Phisalaphong *et al.*, 2006; Coleman *et al.*, 2007). Since, in this case, a typical alcoholic fermentation in a representative operating temperature range is modelled (20~30 ºC); the effect of temperature on cellular death and other parameters like ethanol production or sugar consumption, which are significant at higher temperatures, were neglected. This latter can be observed in experimental yeast population curves vs. temperature in the winemaking fermentations of Torija *et al*. (2003). Other mass balance parameters of the model proposed by Scaglia *et al.* (2008), including pH, were supposed constant in the fermentation temperature range considered.

Taking account Eq. (2), the effect of fermentation temperature on the maximum specific cellular growth rate, μ_m, has the following form, $\mu_m = \gamma . \frac{T \cdot e^{-\frac{E_a}{R \cdot T}}}{1 + e^{-\frac{\Delta G_d}{R \cdot T}}}$ (3)

γ is the maximum cellular growth rate per Kelvin degree [$h^{-1}K^{-1}$], E_a is the activation energy [kJ $kmol^{-1}$] and ΔG_d [kJ $kmol^{-1}$] is Gibbs free energy change of the fermentation reaction. Both of the mentioned parameters were adjusted by the least-square method, using experimental data obtained from anaerobic lab-scale cultures of *Saccharomyces cerevisiae* (killer) and *Candida cantarelli* yeasts, with Syrah must in batch mode (Toro and Vazquez, 2002). The fermentation temperature is T [K] and R is general gases constant [kJ $kmol^{-1}$ K^{-1}].

In the energy balance (Eq. 4), the assumptions are: heat losses due to CO_2 evolution, water evaporation and ethanol and flavor losses were neglected; the average grape juice-wine density and all physical properties are uniform in the fermenting mass bulk. They are constant with temperature and time as well. Heat transfers by radiation and conduction are negligible. The balance for the energy accumulation in the bioreactor is,

$$\frac{d\left(\rho_r \cdot V_r \cdot Cp_r \cdot T\right)}{dt} = Y_{H/CO_2} \cdot V_r \cdot \frac{dCO_2}{dt} - Q \quad (4)$$

In Eq. (4), ρ_r [kg m^{-3}], V_r [m^3] and Cp_r [W-h kg^{-1} K^{-1}] are density, volume and specific heat of the fermenting mass in the bioreactor. Y_{H/CO_2} [W·h produced/kg CO_2 released] is the energy due to the carbon dioxide released by the bioreaction. It was obtained by stoichiometry (Eq. 1) from $Y_{H/S}$, the likely energetic yield on substrate consumed. At last, Q [W] is the exchanged heat between the fermenting mass and the cooling jacket,

$$Q = F_w \cdot Cp_w \cdot \left(T_{w,out} - T_{w,in}\right) \quad (5)$$

Where, F_w is the cooling water flow rate [kg h^{-1}] and Cp_w is specific heat of water [W-h kg^{-1} K^{-1}]; the cooling water temperature in the jacket inlet is $T_{w,in}$ [K] and in the jacket outlet is $T_{w,out}$ [K] (Perry *et al.*, 1997), $T_{w,out} = T - \frac{T - T_{w,in}}{e^{\frac{U \cdot A_t}{F_w \cdot Cp_w}}}$ (6)

Heat exchange area is A_t. Global heat transfer coefficient, U [W m^{-2} K^{-1}], mostly depends on: convective heat transfer coefficient of fermentation mass, which is assumed constant (Colombié *et al.*, 2007); and the heat transfer coefficient for forced convection of water in the cooling jacket. This one was assumed as an annulus (Kern, 2001) and it is function of F_w. Water properties variations and the fouling factor inside the jacket were neglected. Geometry of the bioreactor, equivalent heat transfer diameter of the cooling jacket annulus and fermentation mass height in the bioreactor were considered by their impact on U (Colombié *et al.*, 2007). Finally, water physicochemical properties are required: density, viscosity and thermal conductivity.

3 Simulations

First, the non-isothermal phenomenological model proposed was tested via simulation in the same nominal experimental conditions of two typical winemaking fermentations FER1 and FER2 at laboratory scale. Toro and Vazquez (2002) have described further details about experimental procedures and analytical determinations used here.

The experimental data set used was attained from cultures carried out in 5 liters capacity containers with: an effective must volume of 3 liters; a temperature control at 23 +/-1°C (296+/-1 K) during the cellular growth phase by means of a cooling water jacket; and weight loss detection. Figure 1 and 2 show two experimental fermentations and the corresponding modelled curves for temperature, viable cells and CO_2 and μ_m evolution.

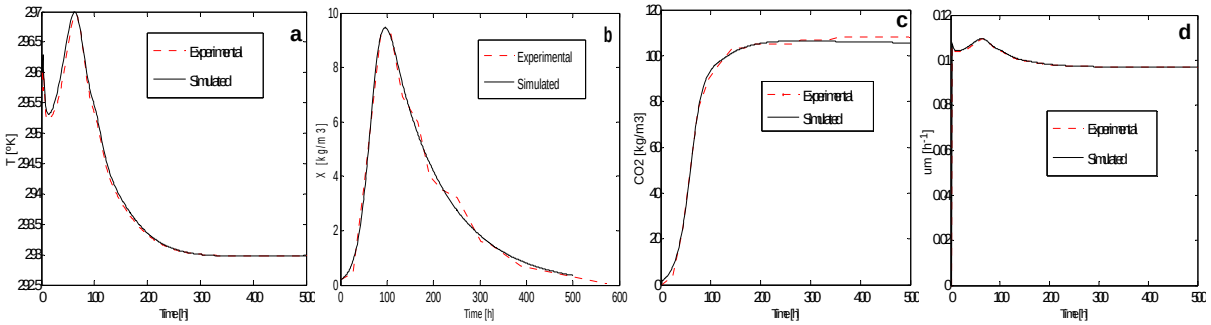

Figure 1. Experimental and modelled curves for fermentation FER1. (a) Fermentation temperature. (b) Viable cells. (c) Carbon dioxide released. (d) Maximum specific growth rate. Experiment at initial (X_0 = 2x10^6 CFU ml^{-1}, S_0 = 208.5 kg m^{-3}, P_0 = $CO_{2,0}$ = 0 kg m^{-3}, T_0 = 296 K) and operating conditions ($F_{w,nominal} \cong$ 0.448 kg h^{-1}, $T_{w,in}$ = 293 K) with *Saccharomyces cerevisiae and/or Candida cantarellii yeasts* inocculated in Syrah must.

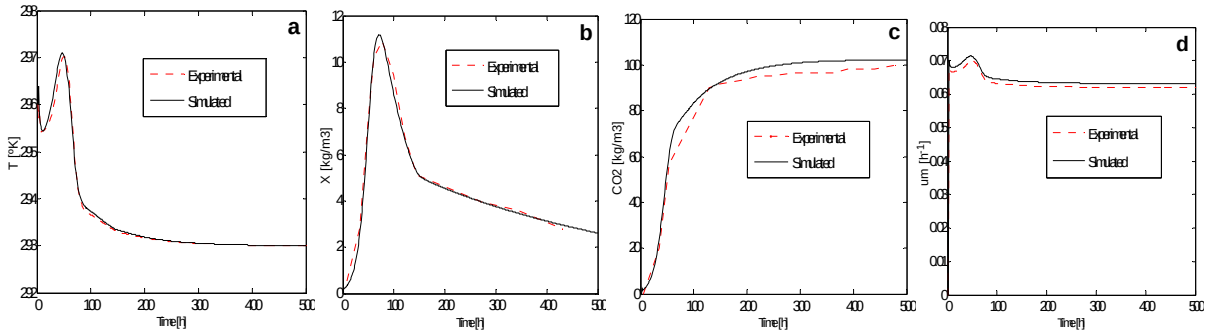

Figure 2. Experimental and modelled curves for fermentation FER2. (a),(b),(c),(d), Idem than Fig. 1. Experiment at similar initial conditions (S_0 = 213.5 kg m^{-3}), same yeasts and must than FER1, with operating conditions ($F_{w,nominal} \cong$ 0.403 kg h^{-1}, $T_{w,in}$ = 293 K).

Second, the model validation was carried out by simulation using different experimental data sets at different constant values of cooling water flow rate and temperature.

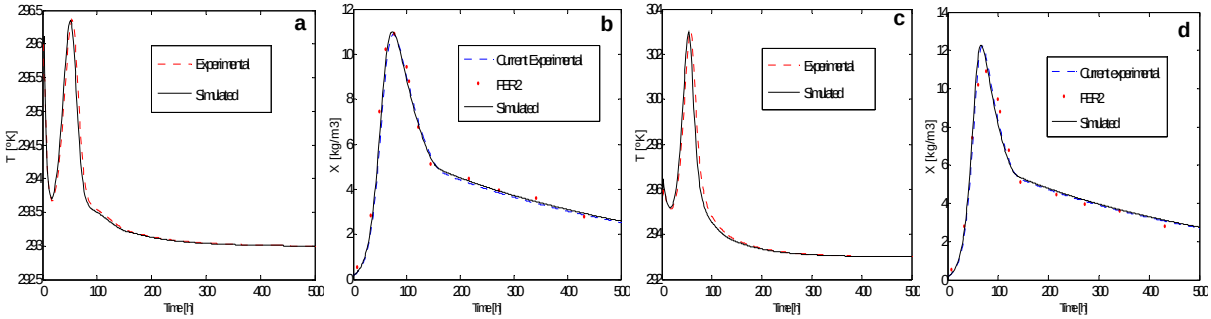

Figure 3. Experimental and modelled curves for fermentation FER3. (a) and (c) Fermentation temperature. (b) and (d) Viable cells concentration. Experiment at same initial conditions, yeasts and must than FER2, but with operating conditions: $T_{w,in}$=293 K in all cases. (a) and (b), F_w = 0.475 kg h^{-1}= constant. (c) and (d), F_w = 0.171 kg h^{-1}= constant.

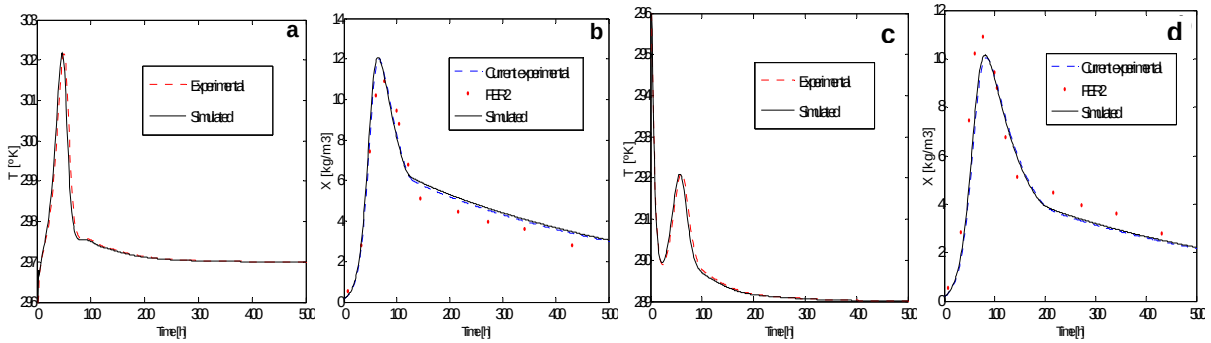

Figure 4. Experimental and modelled curves for fermentation FER4. (a) and (c) Fermentation temperature. (b) and (d) Viable cells concentration. Experiment performed with the same initial conditions, yeasts and must than FER2, but with operating conditions: F_w = 0.403 kg h^{-1} in all cases. (a) and (b) with $T_{w,in}$ = 297 K = constant. (c) and (d) with $T_{w,in}$ = 289 K = constant.

Figures 1 to 4 show the approximation between the experimental and simulated curves for T, X, CO_2 and μ_m. As can be seen, the model proposed has a satisfactory prediction of up to 4 hours in advance regarding experimental fermentation temperature. In addition, all figures reveal that the model is suitable because its error is into an acceptable maximum limit of 3% in respect of variables data ranges, which is compensated with an experimental measurement error of around the same value. Also, all simulations agree with the experimental variables behavior. On the other hand, a fermentation temperature increase occurs due to using a lower flow rate (-60%) or a higher temperature of cooling water (+20%), (Fig. 3c, 3d or 4a, 4b) and vice versa (Fig. 3a, 3b or 4c, 4d) if this is compared with nominal conditions. Finally, the previous considerations are in agreement with experimental published data (Coleman *et al.*, 2007; Colombié *et al.*, 2007; Martínez *et al.*, 1999).

4 Performance analysis

The non-isothermal model was studied in presence of disturbances. Steps changes on most probable manipulated variable in practice, such as the cooling water flow rate, were introduced. A decrease or a shut-down in the cooling water flow can affect the most critical state variable for wine quality, the fermentation temperature. Then, the model performance was evaluated considering responses of μ_m, fermentation temperature and CO_2 evolution (key fermentation measure) to negative step changes, -33% and -70% of nominal F_w (Fig. 5).

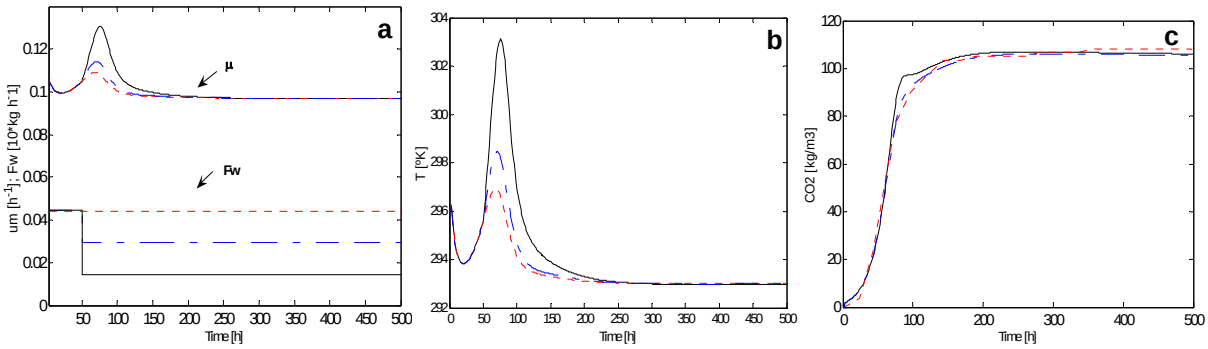

Figure 5. Model responses to steps on the cooling water flow rate. $F_{w,nominal}$ = 0.448 kg h^{-1} (- - -); $F_{w,}$ = 0.30 kg h^{-1} (— - —); $F_{w,}$ = 0.143 kg h^{-1} (—). (a) Maximum specific growth rate and water flow rate. (b) Fermentation temperature. (c) Carbon dioxide released.

In Figure 5, responses to more negative steps on water flow rate each time, up to -70%, can be seen. They produce a positive increase on: maximum growth rate (up to +20%), (a), and maximum fermentation temperature (up to +25%), (b). Moreover, an early positive increase in carbon dioxide released (+14%) at t = 88 hours can be observed, (c); then, a come back to the typical CO_2 trajectory (d). At last, F_w step responses on μ_m and fermentation temperature have a delay of up to 8 hours in both cases, and 14 hours for CO_2 = 86.0 kg m^{-3}. All cases are referred to the nominal simulation with F_w = 0.448 kg h^{-1}; $T_{w,\,in}$ = 293 K was kept constant.

5 Conclusions

An accurate non-isothermal phenomenological model for alcoholic fermentation in winemaking conditions has been presented in this contribution. It is based on a previously developed for the mass balances in isothermal conditions; these were coupled with an energy balance in the bioreactor and its cooling jacket by means of Arrhenius expression. In this sense, cellular growth rate dependence on temperature, at usual operating conditions for typical fermentations, has been considered to improve the prediction. These latter was done to predict key state variables as: viable cells, substrate (sugar) and ethanol concentrations, CO_2 released, and the bioreactor temperature as well. Even so, some model limitation such

the prediction of mentioned variables at fermentation temperatures higher than 30ºC, must be still enhanced.

The proposed model has been adequately validated via simulation with published and own experimental data, showing a suitable behavior and leading to predict in advance the fermentation evolution. Also, a satisfactory performance analysis has been carried out. This allows disposing of a reliable model to approximate state variables trajectories and take suitable control actions on the bioprocess. Hence, its use in different control algorithms can be promising and will be addressed in next works.

Model aided design of gas-lift reactor for oxidation reaction with fast reversible catalyst deactivation

Zuzana Gogová*, Jiří Hanika
Institute of Chemical Process Fundamentals, AS CR, v.v.i., Rozvojová 135/2, 165 02 Prague 6 - Suchdol, Czech Republic

Keywords: Gas-lift reactor, Model, Glucose, Palladium, Catalyst deactivation
Topic: Process synthesis & design

Abstract

Tanks-in-series based model was applied to aid design of gas-lift reactor (GLR), where oxidation reaction along with catalyst reversible deactivation proceeds.

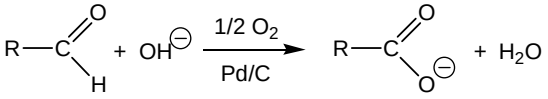
Heterogeneously catalyzed wet air oxidation of glucose dissolved in aqueous alkaline solution served as model reaction. Commercial 2.8% Pd/C catalyst was used in this study. Its advantage is activity at mild conditions with high selectivity towards salt of gluconic acid. But it gets deactivated by the action of oxygen quickly during the reaction course.

Multifunctional gas-lift reactor allows the desired reaction, as well as the catalyst reactivation. Optimal design of the gas-lift reactor makes it possible to keep high and stable activity of the catalyst.

1 Introduction

The model reaction

Glucose (Glc) wet air oxidation is used as the model reaction. It takes place in three-phase medium. The overall reaction can be schematically drawn as follows:



Palladium on activated carbon was used as the catalyst in this study. Results of the model system kinetics study can be found in ref. [1]. The palladium catalyst advantage is the ability to catalyze the reaction at mild conditions selectively towards gluconic acid (Glcac). Its drawback is fast deactivation during the oxidation reaction. This is due to oxidation of the active component surface when oxygen penetrates to Pd subsurface layer [2, 3]. Typically, in one hour the catalyst activity can drop to less than 40% of its original value depending on the reaction conditions. Although the deactivation was proved reversible [4], the rate it takes would present a crucial problem for industrial implementation of the process.

Activation and reactivation of the catalyst is based on reduction the catalyst active sites. Any substance ready to offer its hydrogen can be used for this purpose [5]. Depending on the reductive properties of the particular chemicals to be oxidized in the process, these can be used for the catalyst activation under inert atmosphere. Glucose is good reduction agent to pre-reduce the catalyst.

Solution to the catalyst deactivation problem

Solution to the problem with the catalyst fast reversible deactivation is offered by employment of multifunctional gas-lift reactor (GLR). In GLR, the main reaction, as well as

* Corresponding author. Tel + 420 220 390 349. E-mail:gogova@icpf.cas.cz

the catalyst reactivation proceeds within one reactor unit. In principle, GLR operation is based on spontaneous circulation of catalyst dispersion in liquid, which results from difference in apparent density of the reaction mixture present in riser and downcomer of the reactor. Therefore, if complete separation of the gas phase is ensured after the reaction media passes the riser where the main reaction (and the catalyst deactivation) takes part, the downcomer serves as reactivation zone of the reactor.

The goal of this study was to design a target GLR with optimal geometry for given input conditions, so that the highest possible reactor productivity can be achieved.

2 Theoretical

Mathematical model of gas-lift reactor

GLR mathematical model was derived and applied to aid the target reactor design. Gas-lift reactor is not a simple unit; the GLR mathematical model therefore takes into account that the overall reactor performance is a sum of contributions of each section: the riser, the gas separator, the downcomer and the bottom of the reactor. Each of these sections has its distinct hydrodynamics and its own specific chemistry that is a consequence of different media coming into contact in them. Therefore, the GLR model, as previously introduced by the authors (see reference [6] for more details), consists of two main parts – the first one (hydrodynamics iteration cycle) is to calculate hydrodynamics and optimal geometry based on input adjustable parameters, and second part (reactor performance iteration cycle) uses the results of the first part and calculates the actual GLR performance.

Tanks-in-series model (Figure 1) was employed in the second part of the GLR mathematical model to grasp the way of mixing in real GLR. Every single tank of the tanks-in-series model was described by a set of equations combining hydrodynamics and chemistry that are supposed to hold for the individual section of GLR reactor. The number of tanks that form each section (the riser and downcomer mainly) in the tanks-in-series model corresponds to the extent of axial dispersion in these sections [7, 8], and is set as one of input parameters.

The GLR model was used to firstly aid the target GLR design for given input conditions, and secondly to predict either steady state characteristics of the target reactor, or to find out about transient characteristics as a response to disturbances of its control parameters. Therefore, set of either NAE or ODE is used to mathematically describe the tanks-in-series model [6] depending on the desired outcome from the modelling.

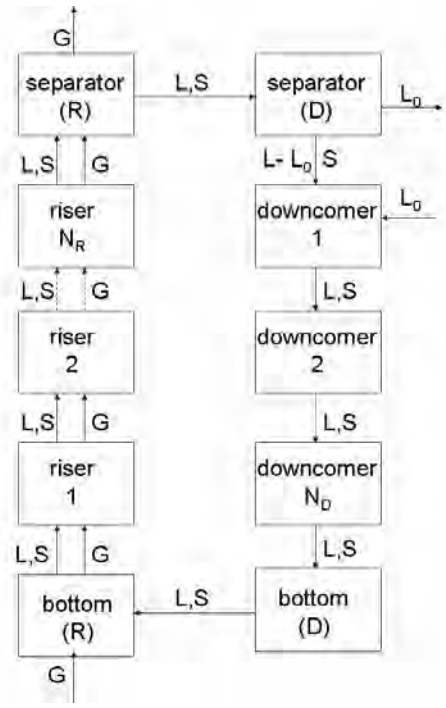


Figure 1: Scheme of tanks-in-series model employed in the "reactor performance iteration cycle" of the GLR mathematical model (see the text above). It enables combining the hydrodynamics and chemistry that are supposed to hold for the individual sections of gas-lift reactor. The tanks-in-series model is employed in continuous mode of operation See the ref. [6] for the GLR model detailed description.

The GLR model parameters

The GLR model parameters form two categories: adjustable operating parameters and non-adjustable parameters. The input adjustable parameters are: degree of Glc conversion, feed (and start-up) concentrations, amount of the catalyst, superficial gas velocity, number of tanks in series, kinetics parameters [1], temperature (30℃), operation pressure (atmospheric). Basic geometrical parameters were adopted from GLR, volume 40L (see [7, 9-11]). This particular reactor has been a source of many correlations employed in the model. Following the procedure described in detail in ref. [6], the input adjustable parameters form a basis to calculate the non-adjustable parameters.

The GLR model assumptions

1) The GLR operates in the region of homogeneous bubbly flow.
2) The downcomer gas hold-up is zero; this can be achieved by appropriate design of separator [12].
3) The number of tanks that form riser and downcomer corresponds to the extent of axial dispersion in these sections. Plus, there are two tanks for each – the bottom and the separator. In the latter two tandems, the sizes of the individual twin tanks vary depending on the respective volumes taken up by either liquid (then they become functional part of downcomer) or G-L dispersion (and then act as a part of riser).
4) Each of the tanks in series operates isothermally at 30℃ and is perfectly mixed.
5) The mathematical model combines description of the GLR hydrodynamics with the kinetics of the glucose oxidation reaction and the catalyst deactivation and reactivation.
6) The reactor operates at low Glc conversions so that 100% selectivity towards gluconic acid can be presumed; based on conclusions of Kunz and Recker [13].
7) The Pd/C catalyst particles (size about 45 μm) are assumed to be homogeneously dispersed in liquid phase. Then it is feasible, for the mathematical description purpose, to accept a concept of pseudo-liquid reaction phase.
8) Constant liquid volumetric flow rate within the reactor sections is assumed i.e. liquid density is constant – independent on the conversion.

3 Results and discussion

The task was to design a target GLR with optimal geometry for given input conditions, so that the highest possible reactor productivity can be achieved. The GLR model was used for this purpose. The presented simulations were run by using commercial software Matlab.

For each set of the input adjustable parameters the location of optimum geometry shifts as a consequence of change in deactivation extent of the catalyst after it passes riser of the GLR. For any deactivation extent always an optimum activation time exists. If the reactivation time is lower, the reactivation process is insufficient. If the reactivation time exceeds its optimum, the time the main reaction could have proceeded is wasted and the reactor productivity drops down. In Figures 2 and 3 the effects of superficial gas velocity and concentration of reactants on the GLR optimum geometry location is shown. The geometrical coordinate is represented by the downcomer-to-riser cross sectional area ratio, A_D/A_R. The GLR productivity is represented by cycle-time-averaged reaction rate, $\bar{\dot{\xi}}_w$, that reaches maximum in the point of the GLR optimal geometry.

During the model reaction kinetics study [1] it was found that the reaction rate is inhibited by oxygen. Moreover, oxygen affects the extent of the catalyst deactivation. The variation range of oxygen concentration is therefore limited in gas feed stream to the GLR. Figure 2 covers major part of the target GLR operational window in terms of U_{GR} and $Y_{OG\text{-}feed}$. It can be seen from Figure 2, that change in $Y_{OG\text{-}feed}$ is compensated to large extent by change in A_D/A_R and the reaction rate responds only slightly to it. In the case of increasing Glc con-

centration (Figure 3), the GLR productivity increases significantly (in the point of the GLR optimal geometry). This is in agreement with the observations from the model reaction kinetics study [1]. As the Glc concentration rises up, the rate of the catalyst reactivation increases as a result of quicker consumption of oxygen. Consequently, the downcomer zone of GLR required for the catalyst reactivation shrinks, too.

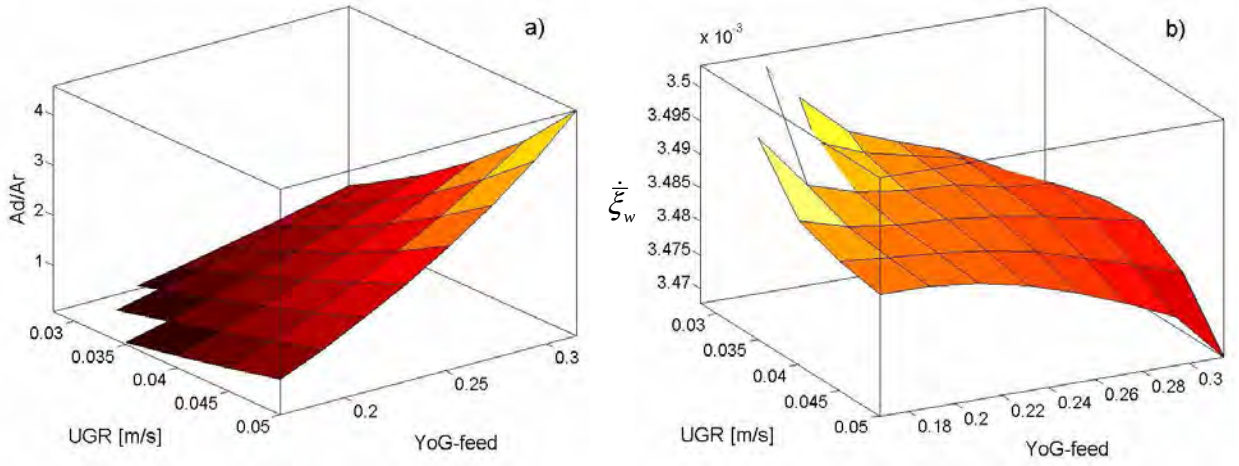

Figure 2: Influence of oxygen concentration in the gas feed ($Y_{OG\text{-}feed}$) stream at various U_{GR} levels on **a)** location of the target GLR optimum geometry; **b)** cycle-time-averaged reaction rate in the point of optimal geometry. Conditions: $C_{Glc\text{-}feed}$=100mol/m^3; $C_{Glcac\text{-}feed}$=0; X_{Glc}=2%.

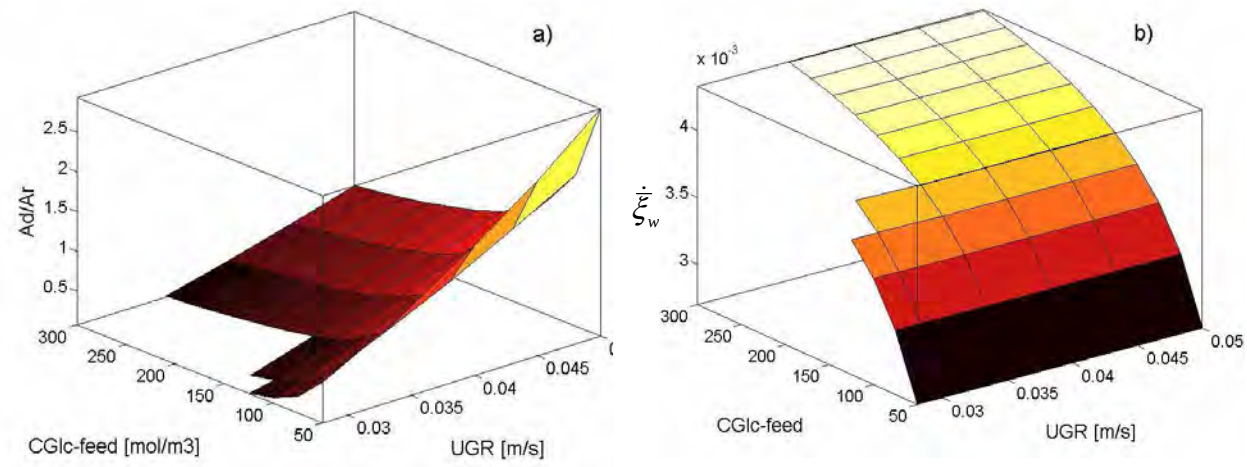

Figure 3: Effect of glucose concentration in the liquid feed stream at various U_{GR} levels on **a)** location of the target GLR optimum geometry; **b)** cycle-time-averaged reaction rate in the point of optimal geometry. Conditions: $Y_{OG\text{-}feed}$=0.21; $C_{Glcac\text{-}feed}$=0; X_{Glc}=2%.

For the input parameters given by the points on the U_{GR}-C_i coordinates in Figures 2a and 3a, the 3D-plane of solutions represents the optimum geometry with the only possible reaction-reactivation time-share to achieve the highest possible cycle-time-averaged reaction rate in the target GLR. Every geometrical solution either above or below the optimum plane would lead to either too long or too short reactivation time, respectively. Any of these two deviations from the optimum geometry result in lower cycle-time-averaged reaction rate than the one achieved in GLR of optimal geometry (Figures 2b and 3b).

In Figure 4, profiles of the actual concentrations and reaction rates along the tanks-in-series are presented for given set of input parameters. Depending on the input conditions the

optimum reaction-reactivation time-share varies and so do the profiles of the reaction rate and the concentrations along the tanks of the tanks-in-series model. As mentioned before, the target GLR operates continuously and these profiles are linked with the points of inlet and discharge from the reactor (see Figure 1). Change in the catalyst fractional coverage by inactive oxygen species, θ_{so}, in Figure 4 indicates change in the catalyst activity. The higher the θ_{so} is, the more the catalyst's activity drops. For more explanation see ref. [1].

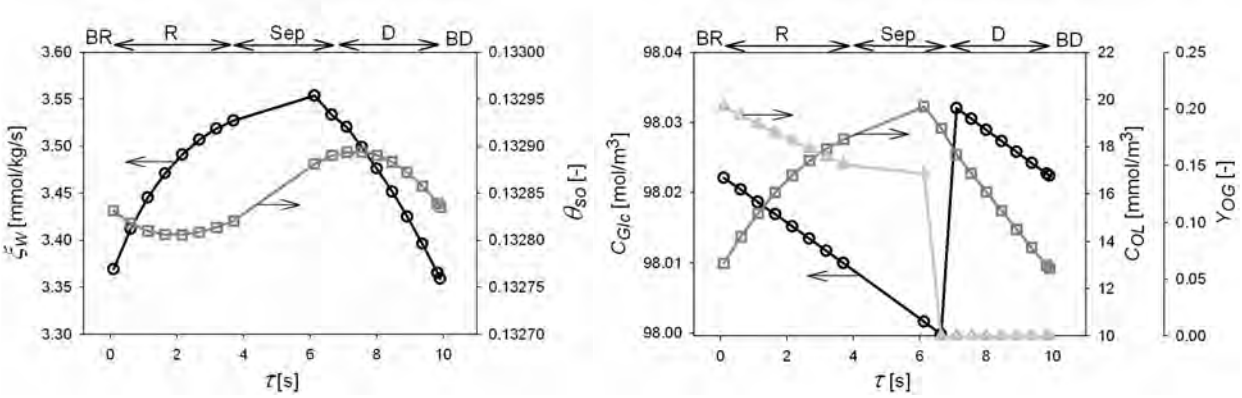

Figure 4: Profiles of the actual reaction rates (circles) and fractional coverage by inactive oxygen (squares) – **left**; Glc (circles) and dissolved oxygen concentrations (squares) and molar fraction of oxygen in the gas phase (triangles) – **right**; in the tanks of the tanks-in-series model (see Figure 1 and the text above for more explanation). Conditions: $C_{Glcac\text{-}feed}$=0; $C_{Glc\text{-}feed}$=100mol/m^3; $Y_{OG\text{-}feed}$=0.21; X_{Glc}=2%; U_{GR}=0.04 m/s; N_R=N_D=7; N_{Sep}=N_B=2; W=80%.

4 Conclusions

GLR mathematical model was used to aid design of target reactor for reaction of heterogeneously catalyzed glucose oxidation. The derived model helps to overcome the problem of the catalyst's fast reversible deactivation by appropriate calculation of the target GLR geometry for any given input conditions.

Topic: Systematic methods and tools for managing the complexity

Abstract

In this paper a novel methodology for biosystems dynamic modelling is presented in which discrete time series, namely AutoRegressive (eXogenous) models are incorporated in the traditional parametric/nonparametric hybrid modelling framework. This results in a set of Delay Differential Equations (DDE) which describe the material balances of a bioreactor system in which dynamic kinetics are mimicked by a parametric/nonparametric submodel. The idea is to display better consistency with the nature of biological systems by associating the dynamics of a cellular metabolism to a parametric/nonparametric subsystem. The proposed hybrid structure is evaluated with fed-batch experimental data taken from a process for antibody expression by recombinant *Pichia pastoris* in addition to two simulation case studies. The first of these assumes a discrete time delay and the second assumes a distributed delay between kinetics. In this paper, it is shown that the proposed hybrid model is capable of modelling discrete and distributed delays between kinetics and outperforms the standard hybrid modelling methods with static kinetic models.

1 Introduction

Time delays have been observed in many bioprocesses and, as is well known, they can be source of instabilities and oscillations. In most cases, however, only a certain time delay between the substrate uptake, biomass growth and product formation is observed such as the case of the growth phase of fed-batch *Saccharomyces cerevisiae* or the *Pichia pastoris* cultivations (Ren et al, 2003). Many phenomenological models that consider discrete delays (Wolkowicz et al, 1997), distributed delays (Daugulis et al, 1997, Wolkowicz and Xia, 1997), ordinary differential equations (ODE) of kinetic rates (Ren et al, 2003) or other time delay considering techniques have been reported. They are usually based on the general mathematical concept of Retarded Functional Differential Equations (RFDE), Bocharov and Rihan (2000). On the one hand, these models are capable of explaining stability of processes and are suitable for the estimation of process key variables. However, on the other hand, their application to other cell systems is limited and their development is cost expensive. In contrast, hybrid modelling has been reported to be a suitable, cost effective alternative capable of being applied to a number of cell systems, Oliveira (2004). Hybrid models combine mechanistic knowledge and process knowledge in form of mechanistic models and data-base nonparametric models. Mechanistic and nonparametric models can be arranged in two possible manners: parallel or serial. In the serial structure, which has been applied in this study, the process dynamics are described by time differentials of process classifying variables and the cell system is mimicked by a parametric/nonparametric submodel. However, until now, cell system dynamics have not been taken into account by these submodels, but it is known that cell systems are sources of time delays. Thus, in this paper, the dynamics of the cell system will be ascribed to the parametric/nonparametric

submodel. Similar techniques as in the case of phenomenological models could be used, for example discrete delays or distributed delays of state variables in the kinetics or differential equations of the kinetics. The latter is not appropriate, because both the kinetic function and the kinetic values remain unknown. Therefore, a solution or estimation of the kinetics is not a straightforward process. Distributed delays are also rather unlikely to be used, due to the fact that a mathematical postulation of arbitrarily large delays for unknown weighting functions of the delayed variable would have to be assumed and this mathematical convenience is in limit biologically unrealistic (Bocharov and Rihan, 2000). Instead, the use of discrete delays in the hybrid model estimated values and in additional measurements, when available, is proposed in this paper. This is analogous to the application of discrete time series, namely AR(X) models. Whereas, in theory, an endless number of time lagged values of one variable can be used as inputs to the nonparametric function, in practice this would lead to long training times and to identification problems of the network structure and parameters (Haykin (1999)). Hence an optimal number of time lagged values exists which represent the proportion between redundancy and the additional gain of information in the inputs. This has been neglected by this paper and instead it has been shown that a limited number of time lagged variable values significantly enhances the prediction capacity of the model and that time lags and the number of time lags have been chosen by trial, which was for example also the case of Parlos et al (2000).

The remainder of the paper is organized as follows. Section 2 presents the embedding of discrete time series into the hybrid parametric/nonparametric structure proposed by Oliveira (2004) along with the changes to the sensitivity equations. The evaluation of the structure which has been presented through the analysis of two simulation cases in addition to experimental fed-batch data of a *Pichia pastoris* process is carried out in section 3. Finally, conclusions are presented in section 4.

2 Hybrid Model Structure

The serial parametric/nonparametric hybrid model structure presented in this paper is shown in figure 1. The structure is based on the originally proposed model by Oliveira (2004). However, in this paper, discrete time series, namely AR(X), are incorporated into the hybrid framework, resulting in a set of DDE for the bioreactor system. Then, the identification of the parameters of the nonparametric function is carried out.

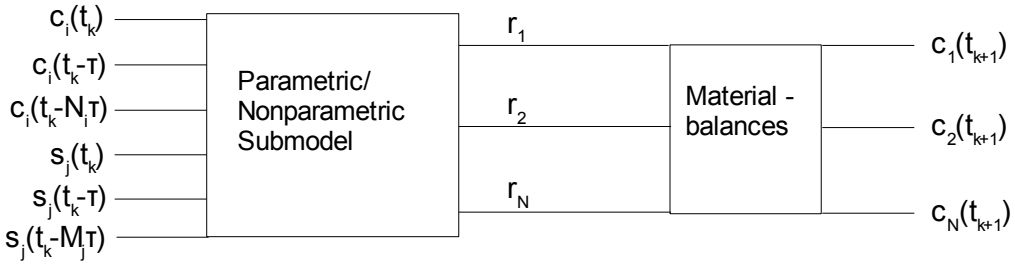

Figure 1: Structure of the proposed serial parametric/nonparametric hybrid model structure

2.1 General hybrid parametric/nonparametric structure

A bioreactor model can be expressed through a set of material balance equations, which describe the dynamics of state variables such as biomass, substrate, product, etc.,

$$\frac{dc}{dt} = r - D \cdot c + u \,. \qquad (1)$$

Here c is a vector of state variables, D is the dilution rate, u is a vector of volumetric control inputs, and r is the kinetic rate vector. The vector of kinetic rates combines, when available, first principle knowledge with nonparametric functions and according to Oliveira (2004) is:

$$r(c,w) = K(\psi_j(c) * \rho_j(X,w)) \,, \qquad (2)$$

where K is a $n \times m$ yield coefficient matrix, ψ_j are m kinetic functions from mechanistic knowledge and where ρ_j are m unknown kinetic functions which have been modelled with nonparametric techniques, X stands for the vector of inputs and w represents the vector of parameters. Nonparametric techniques have the ability of accounting for nonlinear mappings between inputs and outputs. Yet, this nonparametric modelling of the kinetic functions has barely taken the dynamics of the cell system into account, i.e. the input vector only contemplated the current concentration values $c(t)$ and/or the current exogenous inputs $s(t)$. In this study, and in analogy to the AR(X) models, discrete past values of the model outputs and the exogenous input are also contemplated as inputs to the nonparametric function, resulting in the following equation

$$X = \begin{bmatrix} c_i(t), c_i(t-\tau_i), c_i(t-2\cdot\tau_i), \ldots, c_i(t-N_i\cdot\tau_i), \\ s_j(t), s_j(t-\tau_j), s_j(t-2\cdot\tau_j), \ldots, s_j(t-M_j\cdot\tau_j) \end{bmatrix} . \quad (3)$$

In this equation c_i represents the i[th] value of vector c, τ_i is the associated time lag, N_i defines the number of time lags assumed for each value c_i of vector c, s_j is the j[th] exogenous input, τ_j the associated time lag and its lag number is defined by M_j. Note that the time lags and the numbers of time lags, τ_i, τ_i, N_i, and M_j have been chosen by trial as was previously referred to in the introduction. The nonparametric model adopted here is a three layer back propagation ANN with hyperbolic tangent activation function formulated as ρ_j:

$$\rho_j(X, w) = w_2 \cdot g(w_1 \cdot X + b_1) + b_2 , \quad (4)$$

where w is the vector form of the weights and biases, w_1, w_2, and b_1, b_2, respectively. The hyperbolic tangent activation function $g(\cdot)$ is,

$$g(x) = \frac{2}{(1+\exp(-2\cdot x))} - 1 . \quad (5)$$

By merging Equations (1) – (5) it becomes clear that these model equations which describe a bioreactor system with intracellular dynamics are DDEs as “retarded” or “lagged” phenomena are accounted by the nonparametric submodel.

2. The identification of the parameters of the nonparametric submodel

In this study, a least squares criteria of residual concentrations has been adopted to identify the nonparametric model parameters vector w through process data. This criteria is formulated by the following expression:

$$min\left(E = \frac{1}{P \times n} \sum_{l=1}^{P} \sum_{i=1}^{n} \frac{(c_{m,i}(t) - c_i(t, w))^2}{c_{max,i}} \right) , \quad (6)$$

where P represents the number of measured patterns, n is the number of state variables, $c_{m,i}$ are measured state variables, $c_i(w, t)$ represent calculated state variables and $c_{max,i}$ are the scaling factors. The serial hybrid structure of ANN and material balances has been proven to be trained most effectively when using sensitivity approach along with analytical gradients, Oliveira (2004). The analytical gradients are obtained differentiating equation (1) with respect to w while taking the time lagged differential variables into consideration which reads as follows,

$$\frac{d}{dt} \cdot \frac{\partial c}{\partial w} = \sum_{k=0}^{N_i} \left(\frac{\partial (K \cdot \psi \cdot \rho)}{\partial c(t-k\cdot\tau)} \cdot \frac{\partial c(t-k\cdot\tau)}{\partial w} \right) + \frac{\partial K \cdot \psi \cdot \rho}{\partial w} + D \cdot I_n . \quad (7)$$

This least square problem is solved by using the “lsqnonlin” Matlab function which uses a subspace trust region method and is based on the interior-reflective Newton method (Matlab Optimization toolbox) and which favours analytical gradients. The sensitivity equation (7) is integrated along with the delay differential model equations (1)–(5). For integration the differential equations are linearly approximated which results in a time inexpensive algorithm. Unfortunately, some error has been introduced due to this simplification, but if average kinetic rates are estimated for each time step, the error is significantly minimized. Initial

values of sensitivity equations are $(\partial c/\partial w)_{t=0}=0$, as the initial state variables are independent of w and as the gradients $(\partial c/\partial w)_{t<0}=0$ for $t<0$. The residual gradients are then obtained by using the corresponding sensitivity values. It is important to stress that the lagged values of either state variables and exogenous inputs are assumed to be equal to the initial values for all $t-\upsilon\cdot\tau<0$.

3 Results and Discussion

The evaluation of the original and the proposed (DDE) Hybrid Model has been carried out through the analysis of two fed-batch simulation cases in addition to fed-batch experimental data of a *Pichia pastoris* fermentation.

3.1 Simulation cases

In both simulation cases the bioreactor system is modelled by material balances, resulting in a set of differential equations of biomass, substrate and product concentrations and also of the reactor volume, in which the kinetics are expressed as follows. The substrate uptake rate is modelled with Monod kinetics and depends on the current substrate concentration. Specific growth is composed from some bias which accounts for maintenance and the Monod kinetics of a lag variable. Product formation depends linearly on the specific biomass growth. For the lag variable two different approaches have been adopted. The first, was inspired by Wolkowicz and Xia (1997), and it considers a discrete time lag in the substrate concentration as the lag variable. The second, which was inspired by Daugulis et al (1997), Wolkowicz et al (1997), considers distributed delays in the substrate concentration to be the lag variable. The substrate feeding in both cases is linearly controlled in regards to user desired set points of substrate concentrations.

For the evaluation of the DDE hybrid structure, three sets of data, namely training, validation and test data, have been used. This data consist of simulated fed-batches in which concentrations of biomass, substrate and product, the reactor volume and as well the feeding concentration are assumed to be the measured data.

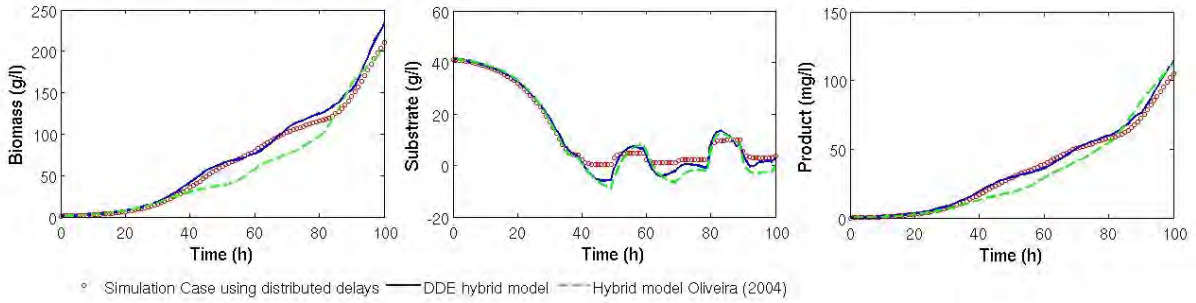

Figure 2: Plot of concentrations over time for data obtained with the DDE hybrid model (solid line, blue), the hybrid model Oliveira (2004) (dashed line, green) and the true simulation using the distributed delay model (o, no line, red)

3.1.1 Hybrid Model Structures

The standard hybrid model structure (Oliveira (2004)) and the DDE hybrid model structure describe three state variables: biomass, product and substrate concentration. The kinetics of each of them are estimated by training an Artificial Neural Network (ANN) with the training set. The estimated substrate concentration, in the standard hybrid model, is the only input to the Artificial Neural Network. In contrast, a series of time delays in the estimated substrate concentrations are considered as being inputs to the ANN for the DDE hybrid model.

The training and identification of the best network structure is carried out according to the best value, namely the greatest value, for the Bayesian Information Criteria (BIC) (Burnham and Anderson (2004)), obtained for the validation set. The test set is used to explore the model generalization capabilities.

3.1.2 Results of Simulation Cases

In Table 1 a selection of the best results obtained for both simulation cases with the standard and the DDE hybrid model are presented. The BIC values for the DDE hybrid model are found to be better than those of the standard hybrid model for both simulation cases. The consistency of all the BIC values obtained for different model structures is elevated although it is not presented here. In fact, the enhancement in model prediction has also been reflected in plots of estimated concentrations and "true" concentrations over time, as being exemplary shown for predictions of a fed-batch considering distributed delays in Fig. 2. Therefore, it is possible to conclude that the proposed DDE hybrid model is capable of accounting for all kinds of time delays observed in process by allowing series of time lagged values of state variables as inputs to the nonparametric model. Thus, a significant enhancement is to be expected for the modelling of experimental data.

3.2 Experimental data of antibody expression of recombinant *Pichia pastoris*

Pichia pastoris fermentation finds application here, as time delays between substrate uptake, biomass growth and product formation have been observed (Ren et al (2003)). Data of Temperature, pH, biomass and product concentrations and the accumulated mass of glycerol and methanol were measured as described in Cunha et al (2004). The bioreactor system is modelled by differential equations of biomass and product concentrations and of the reactor volume while other measurements are considered for the identification of kinetics.

3.2.1 Hybrid Model Structure

In total, four data sets of fed-batch fermentations have been recorded, three of which are used for the training of the hybrid model and the last which is used for its validation. Biomass and product concentrations and the reactor volume are used as state variables. Substrate concentrations, ie glycerol and methanol concentrations have unfortunately not been measured, but instead measurements of accumulated mass of feeding of glycerol and methanol were available. The estimated biomass concentration along with measurements of substrates, such as the sum of mass of glycerol and methanol, temperature and pH, at time t, are inputs for the standard hybrid model. It was assumed that the accumulated mass of feeds along with the estimated biomass concentration could compensate for the lack of substrate concentrations. However measured glycerol and methanol concentrations might have lead to an even more accurate representation of the complexity of the system under analysis. For partial compensation of time delayed substrate concentrations, a time delay in the biomass concentration was taken into account. This is due to the assumption that the delay appearing in the cell metabolism is somewhat similar to a time delay of the cell. Such, in addition to the standard hybrid model, the influences of time lags in the estimated biomass concentration and the measuring of temperature, pH, the sum of mass of glycerol and of methanol on the DDE model estimates have been studied separately and subsequently, a joint delay model for the most significant variables and time delays was studied, namely biomass concentration, temperature and the accumulated mass of glycerol and methanol. The identification of the best network structure was carried out as before.

3.2.2 Results for experimental data

A selection of results is presented in Table 1, revealing the best BIC values for the standard hybrid model and the best BIC values of the DDE hybrid model for lagged inputs of biomass concentration, pH and temperature. The influence of time lags on the estimates, when each variable was studied separately, did not result in significant enhancements of the BIC values in comparison to the standard hybrid model and have therefore not been presented here. The BIC values for the combinations of delayed variables, namely biomass concentration, pH and temperature have been found to be significantly better than the ones of the standard hybrid model, see Table 1. The enhancement of combinations of delayed variables in comparison to the separate delayed variables can be explained by the complexity of the system under study. The state of a system is generally characterized by a set of variables. The time delays in the kinetics are provoked by the cell metabolism which experiences a

change of the state of the system with time. Therefore, combinations of time delays in state characterizing variables lead to better BIC values in contrast to when they are analysed separately. In addition they are also biologically more realistic. However it has been clearly demonstrated that the use of some time lagged values of concentration estimations and exogenous measurements significantly enhances the hybrid model's process predictions.

Simulation Case	Model	NN	Time lag (h)	N_i	BIC train	BIC valid	BIC test
Discrete Delays	Standard hybrid model	2	-	-	-12332	-3256	-3399
Discrete Delays	DDE hybrid model	3	5	1	-11115	-2883	-2882

Table 1: Best BIC results of both simulation cases and experimental data for the standard and DDE hybrid model, where NN is the number of nodes in the hidden layer of the ANN

4 Conclusions

In order to account for dynamics in the cell metabolism, discrete time series have been incorporated into the hybrid model originally proposed by Oliveira (2004), leading to Delayed Differential Equations (DDE). More accurate prediction qualities of the DDE hybrid model than those obtained through the standard hybrid model have been achieved when applied to two simulation cases containing either discrete or distributed delays between the kinetics. Therefore, it has been concluded that the DDE hybrid model is capable of accounting for all the time delays observed in bioprocess systems. Expectations in regards to the application to the antibody expression of recombinant *Pichia pastoris* have been met, where a significant enhancement of process prediction has been achieved, in which a limited number of time lagged values of predicted concentration and exogenous measurements have been used.

Topic: Systematic methods and tools for managing the complexity

Abstract

Industry poses different separations problems for diverse compounds recovery. Separation stage is very important for the product cost; it is especially true for the biotechnological products. Liquid-liquid extraction is a widely used separation operation; however it requires separation agents that must fulfill conditions such as low toxicity, high distribution coefficient and selectivity, among others. Therefore, different approaches have been developed to tackle this problem, being computer aided molecular design the most promising alternative. It is an optimization process looking for the best group combination to successfully perform some objective in a given process, including some physical, feasibility and process restrictions. To solve this problem we present a new genetic algorithm that does not show some limitations present in earlier works.

1 Introduction

Computer aided molecular design is an inverse engineering methodology, it has been successfully used by some authors for the generation of different molecules. The molecular design could be understood as an optimization process with various kinds of restrictions: physical, structural properties, etc; defined in function of the molecule structural groups. The CAMD methodology is based on different property estimation methods coupled with an optimization method. In despite of their limitations, the more used alternative for property estimation are group contribution methods.

The optimization problem involved in molecular design is formulated as a mixed integer non linear programming model (MINLP) (Churi & Achenie, 1996, Duvedi & Achenie, 1996, Stefanis, et al., 1996, Hostrup, et al., 1999), but some authors use non linear programming. Due to the high level of complexity, deterministic methods not always find the global optimum and are very susceptible to get trapped in local minima. In contrast, stochastic methods have a greater possibility to find the global optimum and their form of use is very flexible. These are reasons that lead to use of genetic algorithms in this work.

Thanks to the advantages of the genetic algorithms over the other stochastic methods, authors as van Dyk (van Dyk & Nieuwoudt, 2002), Venkatasubramanian (Venkatasabrumanian, et al., 1994) and Xu (Xu & Diwekar, 2005) has used them for solvent design. However, their implementations have some limitations: a) the molecules representation is diverse and often allows the construction of molecules with a low complexity (due to the representation itself and the low maximum number of groups that form the molecule); additionally, almost in all cases the representation permits multiple molecules b) there is a non uniform use of the restrictions of the problem, especially the structural feasibility restrictions, and it is unknown the effect of the problem formulation on the results, c) in despite of the genetic operators used are similar, their probability of use in the algorithm is a parameter to be adjusted by the user, no warranting convergence nor optimality, and d)

the use of different property estimation methods makes difficult the results evaluation and introduces a high uncertainty level in the problem that could change the results.
This work presents an alternative software that aims to alleviate the aforementioned difficulties.

2 Solvent Design

The CAMD software for solvent design is divided in the following way: a routine to construct molecules structurally feasible, another to estimate properties, and a final that encompasses the others and makes the optimization. Every part is described in the following lines.

2.1 Molecule's Construction

The required molecules to initialize the software are constructed in the following way: once the user has defined how many groups are allowed in a molecule (Np), the software chooses the number of terminal groups randomly. That number varies between 1 and Np/2. Terminal groups have a valence of 1. Then, other group with a valence higher than 1 is selected randomly and is connected to some terminal groups according to its valence, leaving a number of bonds free. These connected groups are joined with other random selected groups up to the molecule valence is zero.
For aromatic and cyclic compounds a special routine is used. The software determines the cycle size randomly and it is constructed using only special cyclic groups. For aromatics construction the cycle size is fixed to 6 and it is constructed using only aromatics groups. When appears a cyclic-aliphatic or aromatic-aliphatic group, the aliphatic branch is constructed by the same random selection used before and it is finished with a terminal group. The maximum number of functional groups is restricted to three, considering easy of synthesis heuristic. Constructed molecules must fulfill the Odele-Machietto restrictions (GANI and BRIGNOLE 1983).

2.2 Properties Estimation

The principal properties needed for the estimation of solvent performance are distribution coefficient and selectivity. Melting point, boiling point, Gibbs free energy, solvent loss and density are also included in the design.

2.2.1. Activity coefficient Distribution coefficient, selectivity and solvent loss are functions of activity coefficients. These coefficients are calculated using the Unifac-Dortmund model (Gmehling et al. 1993; Gmehling et al. 2002). In this method, the activity coefficients are estimated as the sum of residual and combinatorial contributions.

$$\ln\gamma_{\mathrm{i}} = \ln\gamma_{\mathrm{i}}^{\mathrm{C}} + \ln\gamma_{\mathrm{i}}^{\mathrm{R}}$$

The combinatorial contribution considers compounds with very different sizes and forms, and it is calculated as:

$$\ln\gamma_{\mathrm{i}}^{\mathrm{C}} = 1 - V_i^{'} + \ln V_i^{'} - 5q_i\left(1 - \frac{V_i}{F_i} + \ln\left(\frac{V_i}{F_i}\right)\right)$$

The parameters $V^{'}_{i,}$ V_i, q_i, r_i y F_i are calculated by the following equations and are functions of the relative van der Waals volumes and areas (R_k y Q_k) for the different groups:

$$V_i^{'} = \frac{r_i^{3/4}}{\sum_j x_j r_j^{3/4}} \qquad V_i = \frac{r_i}{\sum_j x_j r_j} \qquad F_i = \frac{q_i}{\sum_j x_j q_j}$$

$$r_{\mathrm{i}} = \sum \upsilon_k^{(i)} R_k \qquad q_{\mathrm{i}} = \sum \upsilon_k^{(i)} Q_k$$

The residual contribution is calculated as:

$$\ln \gamma_i^R = \sum_k \upsilon_k^{(i)} \left(\ln \Gamma_k - \ln \Gamma_k^{(i)}\right)$$

$$\ln\Gamma_k = Q_k\left(1 - \ln\left(\sum_m \theta_m \Psi_{mk}\right) - \sum_m \frac{\theta_m \Psi_{km}}{\sum_n \theta_n \Psi_{nm}}\right)$$

The group area fraction (Φ_m) and the group mole fraction (X_m) are given by the following equations:

$$\theta_m = \frac{\theta_m X_m}{\sum_n \theta_n X_n} \qquad X_m = \frac{\sum_j \upsilon_m^{(j)} x_j}{\sum_j \sum_n \upsilon_n^{(j)} x_j}$$

The group interaction parameters are temperature dependent by the following expression:

$$\Psi_{nm} = \exp\left[-\frac{\left(a_{nm} + b_{nm}T + c_{nm}T^2\right)}{T}\right]$$

The relative van der Waals volumes and areas, and some group interaction parameters can be found in literature (Gmehling et al. 1993; Gmehling et al. 2002; Weidlich and Gmehling 1987).

2.2.2 **Other estimated properties** Melting and boiling points, density and Gibbs free energy are used as restrictions in the design process. For its estimation the last version of the GCVOL method for density (Ihmels and Gmehling 2003) and the Constantinou and Gani methods for melting point, boiling point and Gibbs free energy are used. To include these restrictions in the design, the method of fitness function penalization is used. Sigmoidal and Gaussian functions were utilized to normalize the constraints. These functions included a special form to take into account the uncertainty on the evaluated properties.

2.3 Genetic Algorithm

For the solution of the problem, an adaptive genetic algorithm called HAEA [42] was used. Genetic search methods have their basis in Darwinian models of natural selection and evolution. Introduced by Holland, the general idea behind genetic algorithms is the evolutionary creation of a new population of individuals from an earlier generation through genetic processes, such as crossover and mutation, and by passing on the better offsprings to the next generation. In general, individuals that are better adapted to their environment will have a better chance of survival and thus pass on their genetic material to the succeeding generations. This approach is expected to lead to generations that become more and more fitted through evolution thus achieving the desired design objective.

2.3.1. Fitness Function Distribution coefficient is the fundamental property studying liquid-liquid extraction; it shows how a compound is distributed between two phases. However, generally a solvent with good extraction capacity shows low selectivity, and the inverse relation is also true. Therefore in this work, the fitness function for solvent design is the product of the distribution coefficient and the selectivity. Selectivity is calculated with the equation suggested by Pretel [41]:

$$\beta = \frac{\gamma_{B,S}^{\infty}}{\gamma_{A,S}^{\infty}} \frac{MW_A}{MW_B}$$

The distribution coefficient is calculated by the following equation:

$$k = \frac{\gamma^{\infty}_{A,B}}{\gamma^{\infty}_{A,S}} \frac{MW_B}{MW_S}$$

Both properties are functions of activity coefficients and molecular weights. The former property is calculated by the Unifac method described above.

2.3.2. Representation Every population individual or molecule is represented in two ways, genotype and phenotype. A tree representation for molecule genotype is employed; in it every node represents a group and the branches, the bonds of every group with other groups. An array of groups of the same molecule is utilized as phenotype; it is used for the genetic operators. Phenotype is an array of groups of the same molecule; it is employed for properties estimation. For example, lactic acid whose structure is CH3CH(OH)COOH, is represented by its genotype (figure 1):

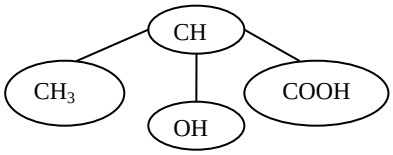

Figure 1. Lactic acid representation

Its phenotype is given by the array (1, 3, 15, 43), where the numbers are the corresponding groups codes (Gmehling et al. 1993).

2.3.3. Population An initial population of 100 individuals was used. The molecules have variable length and a maximum length of 10 groups. In order to achieve a good diversity of the initial population, 10 % of the molecules created are cyclic, 10 % aromatics, and the others aliphatic.

2.3.4. Reproduction For the generation of new individuals four genetic operators were used: mutation, crossover, group insertion y deletion. The operator's probabilities were adjusted with the problem using the adaptive algorithm HAEA.

2.3.4.1. Mutation Initially the program chooses a parent individual randomly, then choose the mutation point and the group to insert according to the residual valence of the fragment (randomly) and make the interchange. Figure 2 shows an example.

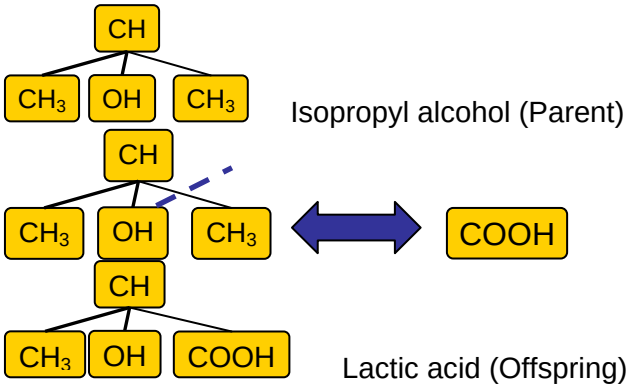

Figure 2. Molecule's mutation example.

2.3.4.2. Cross To do a cross, the program chooses randomly two parent individuals by their fitness and two operation points, one for molecule. Then it makes the fragment interchange, to construct the new molecules. An example is given in figure 3:

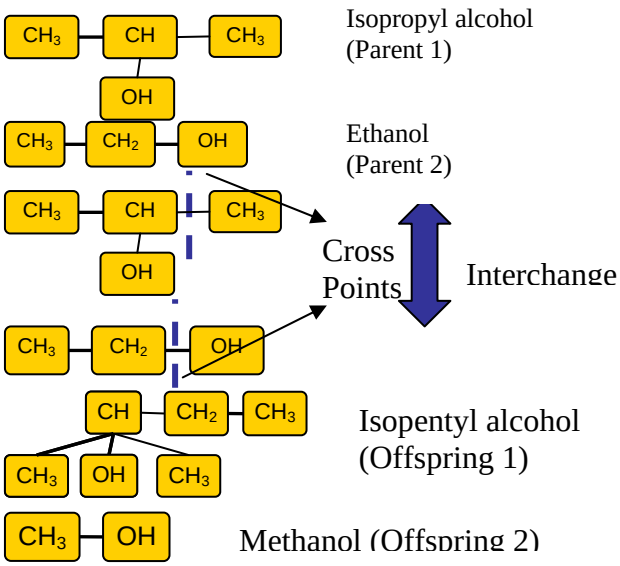

Figure 3. Molecules cross example.

2.3.5. Selection The individual's selection was performed by tournament.

3 Results and Analysis

The design of extractants for acetic acid from an aqueous solution as model problem, and for lactic acid as a biotechnological application was done. The results depicted in figures 4 and 5 are the best compounds obtained in 50 runs of the solvent design problem for each case.

In acetic acid solvent design problem, the designed molecules with the best fitness contain esters, ethers and very often chloride groups. These results are in agreement with the results of Wang and Achenie (Wang and Achenie 2002), Kim Diwekar and Tomazi (KIM et al. 2004) (Kim and Diwekar 2002), and are oxygenated groups such as the groups suggested by Harper (Harper et al. 1999). However, it is clear that a higher number of functional groups into a molecule would give a higher fitness value. Our program does not limit the number of functional groups into a molecule; therefore our solvents are more complex than methyl dimethyl ester and diisobutyl ketone reported previously. However, our molecules have the right groups. Normally, the authors exclude the chloride groups for the design due to their well-know toxic properties. Although we did not exclude these groups, our results indicate a strong affinity between the acetic acid and this kind of compounds. In a future publication we will exclude these groups to design more environmental friendly solvents.

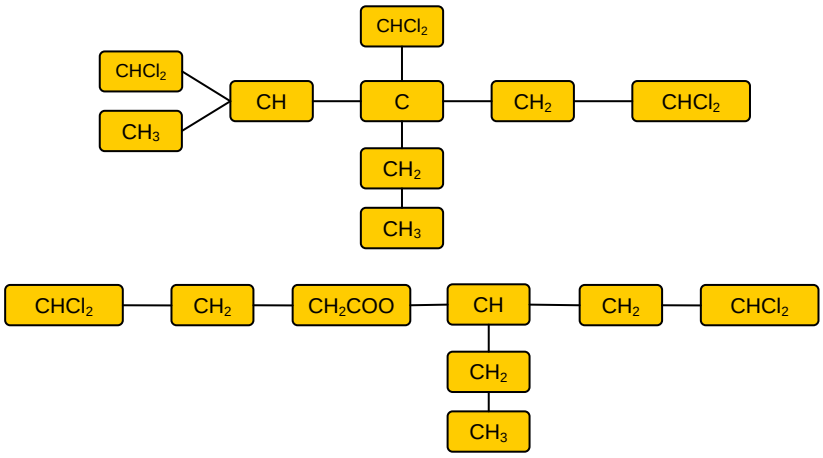

Figure 4. Designed solvents for acetic acid

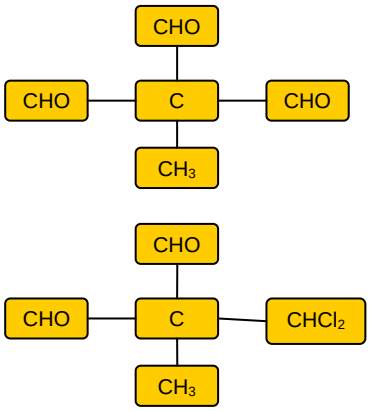

Figure 5. Designed solvents for lactic acid

To our knowledge these are the first published compounds for the extraction of lactic acid. It is apparent that the aldehyde and chloride groups are important part of good solvent molecules. Experimental verification of these results is under development.

4 Conclusions

A solvent design program was constructed and evaluated using two problems.
Our results for acetic acid shows the inclusion in the designed solvents of groups already reported in the literature. The chloride groups are important for this application but its toxic properties excluded them from further consideration.
We present new solvents for lactic acid extraction, they include aldehyde and chloride groups as the most important groups in the design.
New runs of our program without toxics groups are necessary to find better solvents.

Heuristic methods to scheduling operations in parallel machines

José A.V. Oliveira[1*]
[1] DPS – Department of Production and Systems Engineering, University of Minho, Campus de Gualtar, 4710–057 Braga, Portugal.

Keywords: Parallel Machines, Scheduling, Heuristics, Dyeing
Topic: Systematic methods and tools for managing the complexity.

Abstract

This paper presents a study about scheduling a set of tasks in a set of parallel machines. The tasks have setup times that are dependent of the sequence. The problem of planning parallel machines is frequent in the textile industry and this particular case arises in the dyeing section.

This paper presents a constructive algorithm and also a local search procedure. This study also addresses the neighbourhood schemes developed for the problem. Computational results obtained with adapted public instances are presented and discussed.

1 Introduction

Processing in parallel machines is frequent in the textile industry, particularly in the dyeing sector. Figure 1 presents a set of identical parallel dye machines that is a common situation in the textile industry.

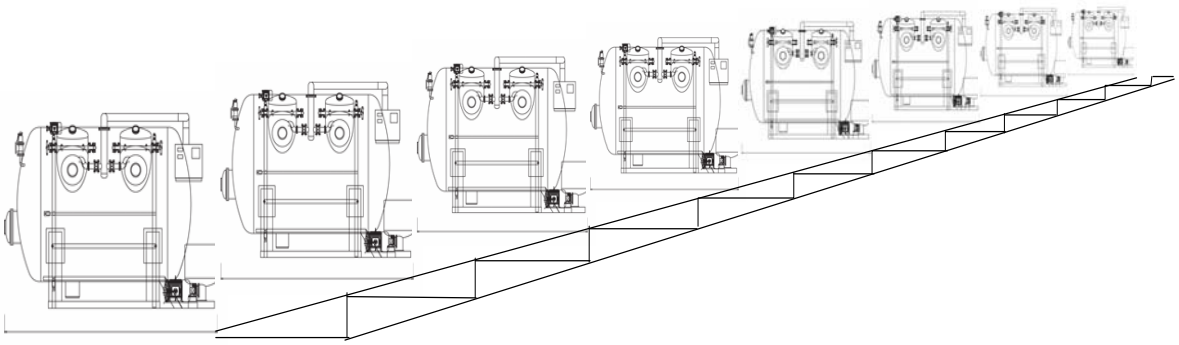

Figure 1 – Dyeing machines

In this paper, a scheduling problem of identical parallel machines is presented in that the orders, with due dates, have different processing times and different priorities. It is still considered the existence of dependent setup times of the sequence. The objective is to minimize the total weighted tardiness of delivering the orders.

This is a difficult problem to solve. It belongs to the NP-hard problems. By that, the use of heuristic methodology is justified. The objective of this study is to test and evaluate the efficiency and the effectiveness of the heuristic methods developed specifically for this problem, and to extend their use in general situations.

* Corresponding author. Tel + 351-253-604763. E-mail:zan@dps.uminho.pt

2 Model Description

The problem of scheduling parallel machines is defined by the set of tasks T to be processed and by the set of machines M available for their processing. Let be:

- the set of *n* tasks, $T = \{t_1, t_2, \ldots, t_i, t_j, \ldots, t_n\}$
- the set of *m* machines, $M = \{M_1, M_2, \ldots, M_k, \ldots, M_m\}$

In this problem the aim is to find a solution that assigns the tasks in T to a machine in M in such a way to complete their processing while respecting the set of imposed constraints. Scheduling problems have the following two main constraints to respect: (1) a machine can only process one task at a time; and (2) a task can be processed only in one machine at a time. Also, it is assumed when a task is started, their processing cannot be interrupted until completed.

The machines are identical and parallel; they perform the same type of operations and have equal processing speed.

At every time it is possible to obtain the following information about the machines:

- the set of instants when the machines M_k became available, represented by the vector $A = [a_1, a_2, \ldots, a_k, \ldots, a_m]^T$;
- the set of tasks that are being processed on the machines M_k, represented by the vector $B = [b_1, b_2, \ldots, b_k, \ldots, b_m]^T$.

The vectors A and B form the matrix $F[A, B, k]$.

The set of tasks T is characterized by the following data:

- the set of processing times, that is necessary to complete the set of tasks t_j, is represented by the vector $P = [p_1, p_2, \ldots, p_j, \ldots, p_n]^T$;
- the set of due dates, that is necessary to delivery the set of tasks t_j without being delayed, is represented by the vector $D = [d_1, d_2, \ldots, d_j, \ldots, d_n]^T$.
- the set of weights that describes the importance of tasks t_j is represented by the vector $W = [w_1, w_2, \ldots, w_j, \ldots, w_n]^T$.

The vectors P, D and W are integrated in the matrix $E = [P, W, D, j]$.

Depending on the sequence of processing the set of tasks, there are different setup times to prepare the machines. The set of setup times is given by the matrix $S = [s_{1j}, s_{2j}, \ldots, s_{nj}]$, for $j = 1, 2, \ldots, n$, where s_{ij} is the setup time of the machine, if the task j follows immediately the task i in terms of sequence. When a task j uses the same dyeing process of task i, $s_{ij} = 0$, i.e. there is no need to prepare the machine. When a task j uses a different dyeing process of task i, $s_{ij} = K$. K represents the amount of time that is necessary to clean the dye machine to be ready for the next task.

Aiming the simplification, this paper considers that all relevant data are integer values, all tasks are available at instant 0, and the processing of the task j is independent of the processing of the task i.

For each task can be calculated the following values:

- instant of conclusion of the processing of the task j, C_j;
- lateness of task j, $L_j = C_j - d_j$;
- tardiness of task j, $T_j = \max\left(0, C_j - d_j\right)$.

With these variables it is built the objective function that represents the total weighted tardiness:

$$\min \sum_{j=1}^{n} w_j T_j$$

3 Constructive Algorithm

In this work, a heuristic of constructive type is presented, that is based in the processing list that assigns the tasks in sequential order to the machines that are available earlier. This list is an ordering of all tasks. Sequentially, the tasks will be assigned one by one to the machine that is available earlier by attending to the ordering defined in the list of processing. In this constructive algorithm, the processing list is defined by the dispatch rule Earliest Due Date (EDD).

Constructive Algorithm

0. Define the processing vector. Use the EDD rule to order the tasks.
1. Choose the task with minimum due date; select a machine that will be available earlier, i.e. a machine with the minimum a_k. Let be j the selected task, k the selected machine, and i the last task processed by k;

   Do:

   $$C^{(n)} = p_j^{(n)} + a_k^{(n)} + s_{ij}^{(n)}$$

   $$L^{(n)} = C^{(n)} - d_j^{(n)}$$

   $$T^{(n)} = w_j^{(n)} \times \max\left(0, L^{(n)}\right)$$

2. Rewrite the line in the matrix F corresponding to the machine k;

   $$F^{(n)} = \left[C^{(n)} \quad j^{(n)} \quad k^{(n)} \right];$$

3. Construct the matrix sol:

   $$sol = \begin{bmatrix} C^{(1)} & j^{(1)} & k^{(1)} & T^{(1)} \\ \vdots & \vdots & \vdots & \vdots \\ C^{(n)} & j^{(n)} & k^{(n)} & T^{(n)} \end{bmatrix}$$

4. Add $T^{(n)}$.

End

4 Local Search

To improve the quality of the results obtained by the constructive algorithm, a local search procedure is implemented. Starting from an initial complete solution, replacing the current

solution by the best solution existing in the neighbourhood of the current solution will be tried iteratively.

The initial solution is obtained by the constructive algorithm based in EDD rule. Starting from the current solution, a swap process is initiated within the list by which the tasks are assigned to the machines. The swap procedure consists in changing the order of two consecutive tasks in the processing list. From this swap results a new solution that is evaluated by the constructive algorithm. Now, instead of using the EDD rule, the tasks are sequenced by the new order defined in the list that respects the operations exchange.

Given a current solution, all solutions that are possible to be obtained by the sway procedure are generated. The solution that produces the lowest value of total weighted tardiness becomes the current solution if it is better than the actual current solution; if not, the search ends, giving the current solution as the local optimum solution. When a current solution is replaced by a new one, the procedure for a generation of a new set of solutions is initiated. This strategy is defined as the best improvement. The adoption of this strategy is justified by the number of new solutions that is possible to be generated by the swap procedure of consecutive tasks. This strategy allows obtaining acceptable computing times.

5 Computational Results

Instances were used based in the instances for the single machine problem available in OR Library from J.E. Beasley. The information for the setup times was added using random values based on the following proportions: 75% of tasks use common chemist processes to clean the dyeing machine; and 25% of tasks use a different process that takes more time to setup the machine, and it was used $K = 24$.

The due date information was updated, dividing by the number of parallel machines. This option intends to keep the same level of congestion that exists in the single machine instances. There were selected instances of size 40, 50, and 100 tasks with different levels of congestion. Also, a small instance with 6 tasks was added. In all greatest instances, it was considered 6 parallel machines; and only 2 machines for the smallest one.

The experiments were performed into two computers. One computer has a CPU Intel Pentium M, processor 760 (2.0 GHz, 533 MHz FSB, 2 MB L2 cache) with 1,00 GB of RAM; the other computer has a CPU Intel Pentium D, processor 3,0 GHz and 0,99 GB of RAM. Both computers use the operative system Microsoft Windows XP with SP2. The results are presented at Table 1.

6 Conclusions

This paper proposes two efficient heuristics to minimise the total weighted tardiness of a set of tasks with known processing times, due dates, weights and family types for identical parallel machines. The exact methods are not appropriate to solve large instances of this problem. The alternative is the use of efficient heuristics methods.

On average, for the used instances, the local search procedure allows for 56% of the total weighted tardiness to be reduced; and for some instances, the local search obtained the optimum solution. Furthermore, the increasing in computation time was not significant.

For this problem it is possible to develop meta-heuristics to improve the objective function values of the solutions. This kind of methods necessarily involves an increase of the computational efforts that can be compensated with the quality improvement of the solutions. As a further work, a genetic algorithm with random keys will be developed.

Topic: Systematic methods and tools for managing the complexity

Abstract

The oil supply chain has a large impact on world wide economics. Therefore, the optimization of each operation in the supply chain will cause impact on the final profit margin. One of the final operations of this chain is the distribution of products, which makes products available to the consumer markets. Thus, it is a challenge to provide an efficient and cost effective distribution so as to enhance the operation profit value as well as the global supply chain value. Such operation often involves pipelines as a reliable and cost effective equipment to transport the final products but, on the other hand, their scheduling appears as a complex problem to be solved so as to answer to market demands coping with transportation and quality approval timings. This work considers an oil products distribution system comprising a refinery, one pipeline and a distribution centre. The objective is to develop a pipeline schedule from a continuous time MILP model that answers to local market demands and distribution centre's conditionings. The prototype of a decioson support tool is presented. This was applied to a real world scenario of Companhia Logística de Combustíveis.

1 Introduction

Supply chain management has continually attracted much attention from several service and industry organizations; due to the fact that companies are constantly looking for new opportunities to cut costs, improve profit margins while maintaining customer satisfaction. Being the oil supply chain one of the most important entities in world wide economy, it is crucial to develop advanced decision support tools to efficiently manage such system. This chain comprises several types of operations, several sites and several workers, at different levels. If, on the one hand, integrated planning and scheduling provides solutions with a wide vision, on the other hand such management tool would be rather complex to build and to use over the complete chain.

Several authors have proposed methodologies addressing different business areas within this chain, from exploration to distribution. Refinery operations remain as the core field, but the left over functions are crucial to take the maximum benefit from the chain. One of these cases is the logistics operations that play an important role in the definition of an efficient flow of goods, services and information.Within such operations, pipelines are widely used in distribution between chain nodes, being reliable equipment for oil and oil products transportation, with reduced costs for a long term solution. Pipeline transportation scheduling has been addressed by some authors through both continuous and discrete mathematical programming models, such as Rejowski and Pinto (2008), Magatão *et al.* (2004), Cafaro and Cerdá (2008). In these works, pipelines are already fairly represented, but no effort has been done to represent tank farms with all physical tanks and mandatory inventory management procedures, which was first proposed by Relvas *et al.* (2006).

* Corresponding author. Tel +351 214 233 550. E-mail: susanaicr@ist.utl.pt

Furthermore, the complexity of this type of systems also includes a high level of uncertainty. In this sense, scheduling plans must be flexible to accommodate unforeseen situations that dictate new restrictions. Reactive scheduling procedures have been proposed for general production plants and situations, having a significant gap to be applied to pipeline systems. Within this context, Relvas *et al.* (2007) proposed a reactive scheduling procedure for pipeline systems, tackling several specific situations that are likely to happen. These situations were modelled through a Mixed-Integer Linear Programming (MILP) formulation.

In order to tackle an effective inventory management, a detailed MILP model was developed, which uses as basis the model develop by Relvas *et al.* (2006). In this way, individual tanks are represented rather than aggregated storage capacities. Finally, being the approach directed for real world applicability, it was necessary to develop a sequencing heuristic that provides pumping sequences of products so as to reduce model complexity.

In this work, it is proposed a framework for a decision support tool that defines pipeline operations and inventory management at final distribution centres, combining the MILP model proposed by Relvas *et al.* (2006) and the reactive scheduling approach proposed by Relvas *et al.* (2007), being validated by Companhia Logística de Combustíveis case study.

2 Problem Characteristics

This work addresses the system described in Figure 1, comprising a pipeline transporting several oil products between one refinery and one distribution centre positioned in a local market. The transportation within the pipeline has to respect possible sequences of products and flowrate constraints. At the distribution centre each tank as fixed product service. Each new batch discharged from the pipeline has to settle for a minimum amount of time, varying with the product. Clients are satisfied on site and forecasts are available on a daily basis. The pipeline schedule should accomplish the availabilities at the distribution centre, and satisfy the complete set of demands.

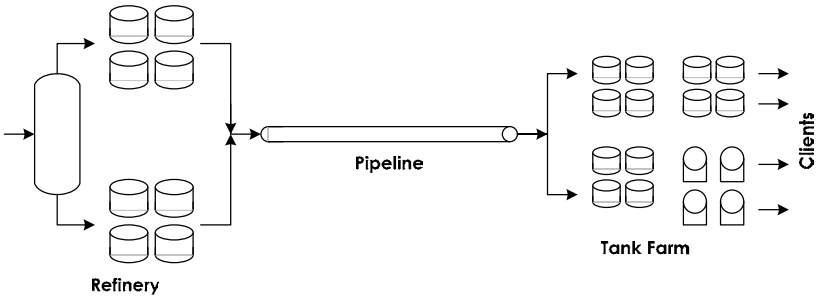

Figure 1 – Operating system

Given: a) the number of products to be transported, b) the matrix of possible/forbidden sequences between pairs of products in pipeline transit, c) the allocation of products to tanks, d) the maximum storage capacity for each product and for each tank, e) the pipeline capacity, f) the pumping rate limits, g) the minimum settling period for each product, h) the time horizon extent and the total number of days to be considered, i) the maximum number of allowable batches to be pumped to the pipeline during the time horizon, j) the initial inventory of each product in each tank, k) the initial state of each tank, l) the daily clients' demands for each product, m) the planned pipeline stoppages;

It is desired to determine: 1) the optimal pipeline schedule, with sequence of products, batches' volumes, pumping rates and pumping/discharging timings and 2) the inventory management at the distribution centre, including daily volume balances by product/tank, monitoring of arrivals, settling and approving tasks and satisfaction of daily clients' demands.

Subject to: an objective function that optimizes operational variables, such as minimising medium flowrate, maximising pipeline usage and the product with lowest final inventory level.

3 MILP Models

To tackle the problem defined above two models have been developed. The model develop by Relvas *et al.* (2006, 2007) adopts a strategy of aggregating storage capacity, i.e., each product is stored in a single tank that has a capacity equal to the total capacity available in the real tanks. This model is referred as Aggregated Tanks' Formulation (ATF). On the other hand, if a detailed inventory management representation is required, a second model developed from the ATF is proposed where each real thank is a single model entity. This is the Disaggregated Tanks' Formulation (DTF).

The main characteristics of these models remain in the time and volume scales, demand and settling period representations. Both models use a continuous time and volume representations. The time scale is build from the sequencing variables that represent the pumping sequence. The volume scale is updated at each time interval where each product located inside of the pipeline moves towards the pipeline end in an amount equal to the volume of the most recent pumped product.

The demand is usually provided on a discrete basis. Thus, it is necessary to translate this information in continuous form. This is done through a time operator that compares both time scales, allocating discrete time points to continuous time intervals.

The settling period is one if the system conditions that restricts the pipeline operation. Settling periods are mandatory for each new batch that is discharged from the pipeline to the tank farm. Within this time intervals, product quality is improved due to settling and meanwhile product approval is obtained.

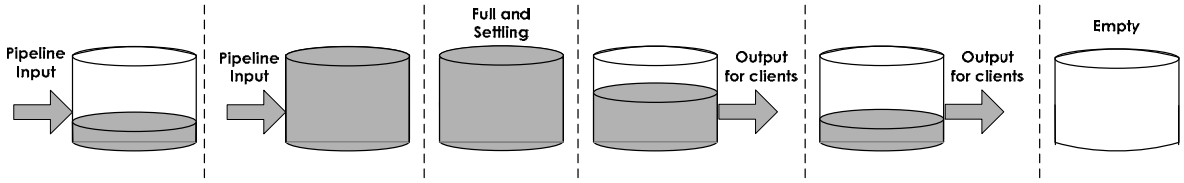

Figure 2 - Individual tank's operational cycle

The approach used to represent the settling period differs between the ATF and the DTF. In the ATF it is mandatory that the fraction of product that corresponds to new batch is maintained in settling (not suitable for clients' demands fulfilment) until the minimum period is reached. On the other hand, as the DTF undertakes individual tank representation, the receiving tank is kept settling until the minimum amount of time is reached.

The DTF uses binary variables that represent and control tank states, which are detailed in Figure 2. A regular tank cycle is composed by a period of pipeline input that fulfils tank capacity. At this point the tank starts to settle until the minimum settling period is reached. At this point it is ready to fulfil market demands until it is totally empty, returning to the starting point. Despite being a more complex model, the detail level of the DTF enables an efficient inventory management at the distribution centre, enabling schedulers precise information of tanks states and how to operate the pipeline reception and product delivery operations.

4 Support Tools: Reactive Scheduling Procedure and Sequencing Heuristic

The implementation of such models in real world scenarios requires attention on two essential points: system dynamics and to obtain results in real time. System dynamics motivates the development of a reactive scheduling procedure that receives an unforeseen situation and integrates it in a new schedule with minimum deviation from the previous one. Six possible causes for rescheduling are presented in Table 1, which have been typified through the analysis of real plant occurrences. These situations are modelled through a MILP representation. Whenever a situation occurs, the corresponding formulation is included in the model formulation. The objective is to readjust the current schedule and incorporate the new situation minimising the amount of changes required. This is a critical step because it

ensures to the refinery production that the changes required are minimal and accommodated in the current plant production and storage profiles.

On the other hand, to obtain results in real time it is essential to explore support techniques that reduce complexity, minimising the solution search effort, such as an initialization heuristic. This heuristic is used prior to model run and reduces the search space. The heuristic receives as input the initial inventory and market demands. The objective is to find the product that would stock out in first place if no pipeline discharges occur. In this way, priorities are established and a sequence of products is developed, corresponding to the given scenario. A second result can be obtain from this heuristic. Given market demands and medium batch volume by product, it can be obtained in advance the number of batches to pump from each product so as to restore product inventory levels.

Table 1 – Rescheduling situations

Situation		Description
S1	Clients' demands	Adjustments on demands on a periodic basis, e.g. weekly.
S2	Imposition on products' sequence	Due to inventory management reasons (at the refinery or tank farm).
S3	Unpredicted pipeline stoppages	Due to product shortage at the refinery or operational conditions (at the refinery or tank farm).
S4	Lots' volumes changes	Mainly due to refinery imposition (e.g. product shortage).
S5	Flowrate adjustments	Mainly due to answering quickly to an unexpected client demand.
S6	Variation on maximum storage capacity	Due to tanks' maintenance, which take place when the tank is empty.

5 Decision Support Framework

The integration of the current models with the proposed supporting tools enables the development of the decision support system architecture presented in Figure 3. Information can be used in a shared way to take advantages from the synergies between modules.

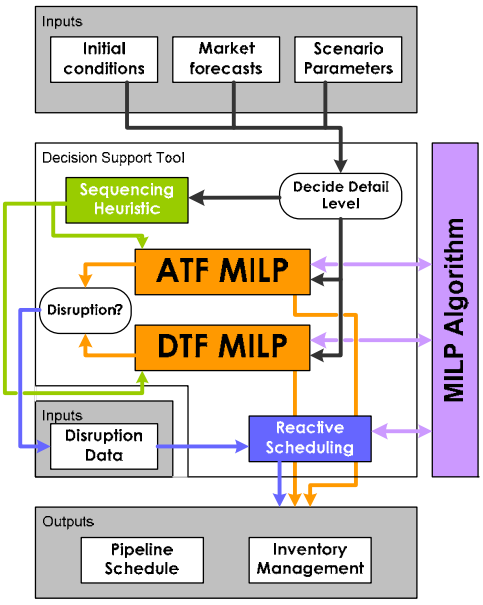

Figure 3 – Decision Support System Architecture

Inputs required are initial conditions (inventory, tank states, pipeline contents), market forecasts and scenario parameters (e.g. flowrate limits, time horizon) while outputs are the pipeline schedule and tank management prodedures with two different levels of detail.

Before running the model, it is necessary to define whether the sequencing heuristic is used and which level of detail is required. The ATF is suitable for medium term horizons, providing

pipeline schedules for refinery production plans and giving an overview for chain management. The DTF detail has high interest to the distribution schedulers, combining the pipeline schedule with an effective inventory management between available individual tanks being suitable for short-term periods. Whenever a disruption occurs, the reactive scheduling procedure is activated, providing a new schedule that incorporates the new occurences. Both MILP models are run in a MILP algorithm.

6 Model Implementation and Results

The real world scenario of CLC – Companhia Logística de Combustíveis has been used as a case study. This company transports six oil products (P1-P6) from Galpenergia Sines' Refinery and distributes them in the central region of Portugal. The distribution centre comprises 29 tanks, whose product service is fixed. The MILP models were implemented in GAMS/CPLEX and results were obtained for medium and short term horizons. The reactive scheduling has been used to address several types of occurrences, while a sequencing heuristic provides valid pumping sequences, which are given to the model as parameters.

As scenario it will be taken the month of July 2007, where several studies were made i) develop several pumping sequences using the sequencing heuristic and implement them in the ATF model, ii) the chosen sequence will be used in the pipeline schedule, giving origin to a detailed inventory management for the first week with the DTF model and iii) the reactive scheduling procedure so as to face unforeseen situations occurring during July 2007.

- When implementing the sequencing heuristic it was verified that product P2 was the one with highest priority to be pumped. In this way, pumping sequences were developed placing this product as earlier as possible in the pipeline transportation schedule. The termination criteria is to finish the monthly schedule with the pipeline filled up with P1. Five sequences were developed, being the final decision taken over the operational indicators results as presented in Table 2. Sequence 5, with a total of 41 batches, was the selected candidate due to fact that operational results are the most consistent (lowest medium flowrate or flexible minimum inventories by product).

Table 2 – Operational indicators by sequence candidate

Sequence	2	3	4	5	CLC
Medium Flowrate (m^3/h)	510.63	511.04	511.04	**510.49**	557.59
∆Inventário (m^3)	+380	+680	+680	**+280**	+19580
Pipeline Usage (%)	**98.66**	**98.66**	**98.66**	**98.66**	94.97
Total Final Inventory (%)	55.34	**55.50**	**55.50**	55.29	65.46
Minimum global inventory (%, product)	16.40 (P3)	18.44 (P3)	18.80 (P3)	**21.19 (P3)**	5.31 (P3)
Minimum Final Inventory (%, product)	51.67 (P1)	**52.53 (P1)**	**52.53 (P1)**	**52.53 (P1)**	20.51 (P3)
Time of computation (min)	**8.7**	120.5	120.5	120.5	-

- The comparison between the ATF and DTF models can be done through the model statistics presented in Table 3, where it is clearly shown the different model sizes and computational effort when considering the first week of operation of July 2007 and the optimal solutions. For the same problem, the number of binary variables increases significantly as well as the computational effort. On the other hand it is obtained a broader set of results comprising specific and detailed procedures for inventory management.

Table 3 – Model statistics

Model	DTF	ATF
# Continuous Variables	3112	3190
# Binary Variables	2199	890
# Equations	11474	7273
# Nodes	3533	0
Time of computation (s)	310.875	0.312

- The reactive scheduling procedure was applied in five situations during the month, where one or more situations can be combined in the same reschedule. CLC's schedulers developed six schedule revisions. Table 4 presents the operational results after the last revision undertaken. The model managed to return a lower medium final inventory while using a larger portion of the total time horizon to pump products. However, the balance between inputs and outputs is higher than the one achieved by CLC's schedulers. The number of interfaces inside of the pipeline when pipeline stoppages occurs is an important factor, because it is likely to decrease adjacent product quality.

Table 4 – Reactive scheduling results

Approach	Revision 5 (ATF)	Revision 6 (CLC)
Medium Flowrate (m^3/h)	508.32	518.17
∆Inventário (m^3)	+8899	+3477
Pipeline Usage (%)	96.91	93.66
Total Final Inventory (%)	59.85	56.98
Minimum global inventory (%, product)	23.63 (P6)	10.09 (P6)
Minimum Final Inventory (%, product)	28.21 (P3)	31.97 (P4)
# Interfaces while pipeline is stopped	1	2

7 Conclusions and Further Work

In this paper it was presented a framework composed of several tools developed to improve the scheduling and management tasks of an oil products distribution centre with pipeline feed. From the real world implementation at CLC, the set of approaches has shown significant improvements in achieving optimal schedules and inventory management plans, while offering a wide range of solutions to explore.

As future work it is proposed to enhance the mathematical formulation of the DTF, reducing model complexity by describing real and complete tank operations in the model formulation. Furthermore, it is proposed to develop a decomposition framework that uses both MILP models in a rolling horizon procedure.

This framework is currently under improvement and testing, through a technological cooperation between Instituto Superior Técnico (IST) and CLC where the main objective is the development of a user-ready software for daily operations management at CLC.

WATER USE OPTIMIZATION IN WINE INDUSTRY. DESIGN OF THE WATER AND THE WASTEWATER TREATMENT NETWORK

Patricia Oliver[1], Rosa A. Rodriguez[1*], Stella M. Udaquiola[1]
(1) Instituto de Ingeniería Química -Facultad de Ingeniería -Universidad Nacional de San Juan
Libertador 1109 (O) CEP 5400, San Juan, Argentina

Keywords: winery industry, effluent treatment, integer linear programming, water pinch
Topic: Sustainable process-product development through green chemistry

Abstract

In San Juan, Argentina, one of the main industrial activities is the wine production. Wineries use large quantities of fresh water for cleaning tasks especially during the wine vintage. This study presents two parts: the design of the water and wastewater network. These proposals have been carried out in a winery of San Juan, Argentina. The results proved that a water reduction of 30 % can be achieved, approximately.
The second part of this work attempts to demonstrate that a distributed effluent treatment network leads to reduction of the effluent flowrate to be treated in order to fulfill the permitted contaminant level for discharging in the sewage or a natural water course. The present work combines this technology with an equation system that leads to design a distributed effluent treatment network for batch processes. The obtained network reduces the global treatment flowrate by collecting streams in different groups according to their contaminant concentrations and processing them separately.

1. Introduction

Nowadays water has become a very valuable resource, not only in those regions where it is scarce, but also in those where water is abundant. The origin problem is due to the contamination of natural water sources. In this context it is necessary to develop tools to allow for the design of urban and industrial water networks that optimize water use. If the water requirements are minimized, the water effluent generation will decrease and natural water course contamination will be reduced. That is to say the best way to minimize treatment costs is beginning the analysis at the water input to the industrial plant instead of applying end of pipe methods. In San Juan, Argentina, one of the main industrial activities is the agroindustry, producing olive oil, wine, dried fruits, sweetmeats and canned goods. All of them are seasonal activities, characterized by multibatch processes, with peaks of water and energy requirements. This work presents two parts: the design of the water and wastewater network. These proposals have been carried out in a winery of San Juan, Argentina. Wineries use large quantities of fresh water for cleaning tasks especially during the wine vintage, the season in which the largest amount of water is consumed in the entire region takes place. This work presents a combination of the water pinch technology, which is a graphical tool, with the mathematical modelling, to synthesize the winery water network. Taking into account the wastewater and the results obtained in the previous work, in a centralized treatment system, even if two streams require different treatment operations, they are combined, and both streams undergo each treatment, increasing both capital and operating costs. In a distributed effluent treatment system, in contrast, the streams are segregated and treated separately (Mann G. and Liu Y., 1999). The present work combines this technology with an equation system that leads to design a distributed effluent treatment network for batch processes. The obtained network reduces the global treatment flowrate by collecting streams in different groups according to their contaminant concentrations and processing them separately.

2. Minimum Pure Water Flowrate Determination for an Integrated Process with Reuse

The limiting contaminants are the ones that restrict the reuse possibilities. The selection is made based on the wastewater characteristics of the industry under study, so that its concentration allows to determine if the output of some water using operation can be reused at the input of others. The chemical oxygen demand (COD) and the total suspended solids (TSS) are important water quality parameters. They do not indicate if there are toxic compounds or pathogen microorganisms in water but, given that the main water use in wineries is cleanliness, they have been considered sufficiently representative of the water quality. In the context of this work, the word "contaminant", refers to the parameters mentioned above. The data provided is based on actual site measured data using measuring instruments and are average values based on readings taken throughout the day and/or several tests carried out in a big winery in San Juan Capital.

The input and output water flowrate of every water-using operation is considered constant and independent of the input concentration. This means there are no flowrate changes caused by process operations, only changes in the limiting contaminant concentration. The equations for the calculation presented by Mann G.; Liu Y (1999) are the following:

$$\Delta m_{i,tot} = \frac{f_i}{\left(C^{w}_{i,out} - C^{w}_{i,in}\right)} * \frac{1}{10^3} \qquad (1) \qquad C^{\lim}_{i,out} = C^{\lim}_{i,in} + \frac{\Delta m_{i,tot}}{f_i} * 10^3 \qquad (2)$$

Where $C^{w}_{i,in}$ y $C^{w}_{i,out}$, are the contaminant concentrations of the water supply and water stream that leaves operation i, respectively; f_i, is the water flowrate required by operation i; $C^{lim}_{i,in}$ y C^{lim}_{out},, are the limiting contaminant concentrations at the input and output of operation i, respectively; and $\Delta m_{i,tot}$, is the total contaminant mass load transferred from operation i. The reuse possibilities are determined considering all the water using operations of the process simultaneously and, water reuse is preferred instead of freshwater use in each stage. The effluent of a water using operation can be reused into another only if the contaminant level of the first one does not interfere with the second one. In those systems where two contaminants are considered for the analysis, the mass transfer between them is considered proportional as Eq. (3) points out.

$$\frac{C_{iA,n} - C_{iA,in}}{C_{iAout} - C_{iAin}} = \frac{C_{iB,n} - C_{iBin}}{C_{iB,out} - C_{iB,in}} \qquad (3)$$

Where $C_{i,A,in}$, $C_{i,A,out}$, and $C_{i,A,n}$, are the contaminant A concentrations of operation i at the input, at the output and, at the concentration interval n, respectively. The concentration interval boundaries are determined from the limiting inlet and outlet concentrations for each water using operation from the limiting process data. The same definitions apply for contaminant B. The flowrates determined above are apparent minimum freshwater flowrates since they have been determined without considering the contaminants influence on each other. The solution of the following equation system for every concentration interval leads to the determination of reuse flowrates and limiting contaminants concentrations of each water using operations.

$$f^{*}_{i,n} = \theta_{i,n} f_i \qquad \text{(Necessary water flowrate for operation } i\text{)} \qquad (4)$$

Where $f^{*}_{i,n}$, is the actual flowrate of operation i at the concentration interval boundary n; $\theta_{i,n}$, is a fraction from 0 to 1 and; f_i, is the limiting flowrate of operation i.

Global water balance in interval *n*.

$$f^{*}_{i,n} = T_{i,n} + q_{li,m \le n} + F_{i,n} = \theta_{i,n} f_i \qquad (5) \qquad \text{where } \theta_{i,n} = \max_j \left[\frac{C_{ij,n+1} - C_{ij,n}}{C_{ij,n+1} - \overline{W}_{ij,n}} \right] \qquad (6)$$

Flowrate-weighted average concentration of the three sources of water considered in the global balance.

$$\overline{W}_{ij,n} = \frac{T_{i,n}W_{ij,n} + \sum_{l} q_{li,m\leq n}W_{lj,m\leq n}}{T_{i,n} + \sum_{l} q_{li,m\leq n} + F_{i,n}} \quad (7)$$

In Eq. (5) to (7), $T_{i,n}$, is the flowrate of water available for reuse within operation i at concentration interval boundary and $W_{ij,n}$ is the correponding concentration of contaminant j; $q_{li,m\leq n}$, is the flowrate of water from operation i at the concentration interval boundary n that is reused from operation l at concentration interval boundary m smaller than n and $W_{lj,m\leq n}$ is the correponding concentration of contaminant j; $F_{i,n}$, is the flowrate of freshwater supplied to operation i at concentration interval boundary n. The water network obtained after applying the water pinch analysis could be used only if storage tanks are utilized. In this case, 26 storage tanks are necessary; an extremely high number considering the cost implied.

3. Mathematical Optimization. Batch process

To achieve the real water network for a batch process on the industrial scale, water storage tanks must be included in the network. This would allow water supply in due form and time to each water-using operation depending on the quantity and quality requirements.The objective function could be expressed by the following equation:

Objective Function $\min \sum_{i} F_i$ (8)

In order to design a water network for discontinuous process in relation to water use, some constraints must be included in the mathematical model:

1. If the output of operation j can be reused by operation i, then stream j will direct to storage tank t. If operation j' admits water reuse from operation i, then operation j' will be supplied by tank t, which is sink of stream i.
2. Water using operation can be supplied only by a single tank. If water available by tank t for operation i is insufficient, then the lacking flowrate will be supplied with freshwater, Fi. This additional freshwater flowrate, previously, will enter tank t.
3. The excess flowrate available for reuse coming from operation i that is stored in tank t is sent to effluent treatment. There are no streams from tank to tank.

Water mass balances. Input/output balances on operation i

$$F_i + \sum_{j} f_{j,i} + f_{t,i} = f_i^{in} \text{ (Real Mixing Node)} \quad (9)$$

$$E_i + \sum_{j'} f_{i,j'} + f_{i,t'} = f_i^{out} \text{ (Real Splitting Node)} \quad (10) \qquad f_i^{in} = f_i^{out} = f_i \quad (11)$$

Input/output balances on tank t

$$\sum_{i} f_{i,t} + F_t + f_{k,t} = f_t^{in} \text{ (Imaginary Mixing Node)} \quad (12)$$

$$E_t + \sum_{i'} f_{t,i'} + f_{t,k'} = f_t^{out} \text{ (Imaginary Splitting Node)} \quad (13) \qquad f_t^{in} - f_t^{out} = f_{Ac} \quad (14)$$

$$x_{i,t} = \frac{f_{i,t}}{f_t^{in}} \quad (15) \qquad x_t^{w} = \frac{F_t}{f_t^{in}} \quad (16)$$

$$x_{t,i'} = \frac{f_{t,i'}}{f_t^{out}} \quad (17) \qquad x_t^{ww} = \frac{E_t}{f_t^{out}} \quad (18)$$

$$\sum_{i} x_{i,t} + x_t^{w} = 1 \quad (19) \qquad \sum_{i'} x_{t,i'} + x_t^{ww} = 1 \quad (20)$$

Contaminant mass balances. Balances on operation i

$$f_i * c_i^{in} = \sum_j \left(f_{j,i} * c_{j,i}^{out} \right) + f_{t,i}^{out} * c_{t,i}^{out} \quad (21) \qquad f_i * c_i^{out} = f_i * c_i^{in} + \Delta m_i \quad (22)$$

$$\Delta m_i = f_i^{fixed} * \left(c_i^{out,\max} - c_i^{in,\max} \right) \quad (23)$$

Balances on tank t

$$c_t^{out} = c_t^{in} = c_t \quad (24) \qquad f_t^{in} * c_t^{in} = \sum_i \left(f_{i,t} * c_i^{out} \right) \quad (25)$$

Restrictions

$$f_i \geq f_i^{fixed} \quad (26) \qquad c_{j,i}^{out} \leq c_i^{in,\max} \quad \forall i \neq j \quad (27)$$

$$c_{t,i}^{out} \leq c_i^{in,\max} \quad (28) \qquad c_t = \max \left(c_{j,t}^{out}, c_k \right)_t \quad \forall k \neq t \quad (29)$$

$$c_i^{in} = \max \left(c_j^{out}; c_t \right)_i \quad \forall j \neq i \quad (30)$$

Fig. 1 shows the water network obtained considering the discontinuous use of water in the wine industry.

4. Minimum Treatment Flowrate

The treatment cost is optimized minimizing the inlet flowrate to the treatment process. The effluent flowrate is assumed to be constant. To begin with the analysis, the following heuristics have been considered.

1. Those effluent streams with contaminant concentration higher than that of the treatment pinch are only partially-treated, and those effluent streams with contaminant concentration equal to that of the treatment pinch must be treated completely.
2. Those effluent streams with contaminant concentration lower than that of the treatment pinch can bypass the treatment.
3. The treatment cost is proportional to the effluent flowrate to depurate. The treatment process that admits the highest contaminant concentration at the input must be the first one. The least expensive treatment must be run at the maximum possible flowrate. Physical and chemical treatments must come before the biological ones.The easiest treatment to control must be run at the maximum possible flowrate.

Input/output concentrations, removed contaminant mass loads and treatment flowrates, are determined solving the following equation system:

$$f^I = máx \left(\frac{m_i}{\Delta c_i} \right) \quad (38) \qquad c_{in}^I = c_e + \left(\frac{\Delta m_{total}}{f^I} \right) * 10^3 \quad (39)$$

$$c_{out}^I = c_{in}^I * \left(1 - r^I \right) \quad (40)$$

$$\Delta m^I = \frac{f^I * \left(c_{in}^I - c_{out}^I \right)}{10^3} \quad (41) \qquad c_{in}^{II} = c_{out}^I \quad (42)$$

$$c_{out}^{II} = c_{in}^{II} * \left(1 - r^{II} \right) \quad (43) \qquad c_{i,out}^I = c_{i,in}^I * \left(1 - r^I \right) \quad (44)$$

$$c_{i,in}^{II} = c_{i,out}^I \quad (45) \qquad c_{i,out}^{II} = c_{i,in}^{II} * \left(1 - r^{II} \right) \quad (46)$$

The ratio of stream i that can bypass treatment II is determined solving equation 10 iteratively up to $f_{(n-x)}^{II} < f_{(n-x)}$, which means until one stream has to be divided into two smaller ones, one of which is processed by the two available treatments and the other one, just by treatment I.

$$c_e = \left[\frac{f_1^{II} * c_{1,out}^{II} + f_2^{II} * c_{2,out}^{II} + \ldots + f_{(n-2)}^{II} * c_{(n-2),out}^{II} + \left(f_{(n-2)} - f_{(n-2)}^{II}\right) * c_{(n-2),out}^{I} + f_{(n-1)} * c_{(n-1),out}^{I} + f_n * c_{n,out}^{I}}{\sum_{i=1}^{n} f_i} \right] \quad (47)$$

In multiple contaminants and multiple treatment process systems, for a given treatment process h, a good estimate of the minimum flowrate is the maximum flowrate among the minimum treatment flowrates for all contaminants, that is(Mann G. and Y. A. Liu, 1999):

$$f_{\min}^{h} = \max_{k}\left(f_{k,\min}^{h}\right) \quad \text{(minimum treatment flowrate for treatment process h and contaminant k)} \quad (48)$$

The following results correspond to the second part of a study to optimize the water use, made in a winery in San Juan, Argentina. The maximum concentrations permitted for discharging in a natural water course are: TSS: 40 ppm and COD: 75 ppm. The starting point to design a multiple treatment network is the synthesis of subnetworks for each contaminant according to the minimum flowrates determined above. Then, these subnetworks are merged and once all simplifications are made, the optimal treatment network design is achieved. Fig. 2 shows the resulted network.

5. Conclusions

An approach to synthesize the optimal water network for batch processes has been developed. The new formulation combines the water pinch technology, to determine the minimum water requirement, with the mathematical modelling, to design the water network for batch processes that satisfies the minimum water requirement and requires the minimum amount of tanks. The percentages in which the freshwater flowrates can be reduced compared with those of the actual situation of the plant is 30.22%. With regard to the effluents, it has been proved that optimizing the treatment network the treatment flowrates are minimized. These reductions, besides to make smaller the treatment installations, facilitate the treatment because, the smaller the flowrate to depurate, the easier the treatment.The methodology applied in this work is a feasible and useful tool to implement in the processing plants that generate several effluents that vary greatly in their contaminant concentrations.The distributed effluent treatment network offers the advantage of determining in which treatment unit will be each effluent stream processed so that, in case those that should be treated in the same device were not generated, the corresponding unit operations would not be operated.

Keywords: Heat exchanger network, particle swarm optimisation, Superstructure model, shell and tube heat exchangers design, Bell-Delaware method
Topic: Systematic methods and tools for managing the complexity.

Abstract

Many studies and methodologies to the Heat Exchanger Network (HEN) synthesis were proposed to make possible the energy recovery between process streams, minimizing the utilities consumption and the number of heat transfer equipment.

Most of these formulations assume constant heat-transfer coefficients and counter current arrangement for all stream matches, which can lead to non-optimal results. In the present contribution an optimisation model for the synthesis of HEN that includes a detailed design for each heat exchanger in the network is proposed.

Particle Swarm Optimisation approach has been applied to determine the HEN that minimizes the total annual cost, considering capital costs of heat exchangers, energy costs for utilities and pumping duties. The algorithm combines two distinct models, a superstructure simultaneous optimization model for the HEN synthesis considering stream splitting and a model for the detailed equipment design following rigorously the standards of TEMA.

One example from the literature were used to show the application of the proposed algorithm, and the results confirm the achievement of the optimum HEN configuration with the detailed heat exchangers design using little computational effort.

1 Introduction

One of the most frequent problems in industrial plants is the excessive energy consumption. Heat Exchanger Network (HEN) synthesis has been a well-studied subject over the past decades to solve these problems. Many studies and methodologies were proposed to make possible the energy recovery between process streams, minimizing the utilities consumption, the number of heat transfer equipment and the gaseous and liquid pollutant emissions from the combustible burn and water usage.

Furman and Sahinidis (2002) published a complete review on HEN synthesis. The majority of published papers in HEN synthesis consider constant heat transfer coefficients and countercurrent arrangement for all stream matches. This consideration can achieve solutions very far from the point of view of industrial application because heat transfer coefficients are strongly influenced by the heat exchanger geometry and operational constraints.

A few papers incorporate the design of the heat exchangers in the HEN synthesis. Ravagnani, et al. (2003) presented a methodology for the synthesis of HEN including the thermo-hydraulic design of the heat exchangers. The HEN synthesis is accomplished by using Pinch Analysis. After the synthesis, the network equipment are designed considering pressure drops and fouling with the Bell-Delaware method (Taborek, 1983) for the shell side.

Mizutani et al. (2003b) developed a model for the synthesis of HEN based on a heat exchanger design model (Mizutani et al., 2003a). To the network synthesis, the logic based outer approximation method of Turkay and Grossmann (1996) was used.

Ravagnani and Caballero (2007a) proposed a mathematical model to find the best shell-and-tube heat exchanger configuration, using the Bell-Delaware method for the shell side thermal-hydraulic calculation and following rigorously the standards of the Tubular Exchangers Manufacturers Association (TEMA, 1998).

In this contribution, an optimization procedure for the synthesis of HEN including a detailed design for each heat exchanger in the network is proposed, as presented in Silva et al. (2008). The model takes into account the optimization of the equipments and their geometric and operational constraints from the synthesis stage. Shell and tube pressure drops and fouling are considered, as well as mechanical aspects, like shell and tube bundle diameters, internal and external diameter of tubes, number of tubes, number of baffles, baffles spacing, number of shells, tube length, tube pitch, tube arrangement and the fluid allocation in the heat exchanger.

The approach is based on the use of Particle Swarm Optimization to determine the HEN that minimizes the total annualized cost, accounting for capital costs of heat exchangers and the energy costs for utilities and pumping duties, following the model proposed by Ravagnani et al. (2008). The algorithm combines two distinct models: a superstructure simultaneous optimization model for the HEN synthesis considering stream splitting and by-pass without isothermal mixing similar to the proposed by Yee and Grossmann (1990); and a model for the detailed equipment design, following rigorously the standards of the TEMA.

Mechanical design features and thermal-hydraulic variables (heat, area, individual and global heat transfer coefficient, shell and tube pressure drops and fouling) are variables to be optimized. The equipments are designed under pressure drop and fouling limits. The great contribution of this paper is the incorporation of the equipment detailed design and the achievement of optimal mechanical and thermo-hydraulical variables and the warrantee of the use of the standards of TEMA.

One example from the literature were used to show the application of the proposed method, and the results confirm the achievement of the optimum HEN configuration with the detailed heat exchangers design, following the TEMA standards.

2 Problem Definition

The problem consists of finding the HEN that minimizes the total annual investment plus operating costs. The investment term includes the cost of exchangers and pumps, and the operating costs comprise the energy for utilities and pumps.

Given a set of hot and cold streams with their supply and target temperatures, flowrates and physical properties (density, viscosity, heat capacity and thermal conductivity), pressure drop and fouling limits, as well as hot and cold utilities with their temperatures and corresponding costs, the objective is to find the best HEN configuration with the detailed heat exchangers design concerning the minimum global annual cost, considering utility, area and pumping costs.

For the HEN synthesis an algorithm similar to the stage-wise superstructure representation of Yee and Grossmmann (1990) is proposed. Heaters and coolers are placed at the ends of the streams. This algorithm (main problem) is combined with the heat exchangers design model presented in Ravagnani and Caballero (2007b) for each network equipment, to find the minimum global annual cost, comprising area, utilities and pumping costs. The design of heat exchangers is solved as an inner optimisation loop.

At the HEN optimization problem an objective function to minimize global annual cost is proposed, presented at Eq. (1). The constraints are the thermodynamics restrictions of the heat exchanges, showed in Eq. (2).

The problem to be formulated as an optimisation problem is the design of the optimum shell and tube equipment to exchange heat between a cold and a hot stream. The objective is to find the heat exchanger that presents the minimum cost including exchange area and pumping costs, following the TEMA standards constrained to allowable pressure drops and fouling limits, Eq. (3) and (4).

Minimize: $$C_{GLOBAL} = C_{utilities} + \sum_{k}^{unit} (C_{total})_k \quad (1)$$

Subject to: $$\begin{cases} (Th_{in})_k > (Tc_{out})_k \\ (Th_{out})_k > (Tc_{in})_k \end{cases} \quad k=1,\ldots,\text{number of heatexchangers} \quad (2)$$

Where, k are the heat transfer equipments; Th_{in} and Th_{out} are the inlet and outlet temperatures of the hot streams; Tc_{in} and Tc_{out} are the inlet and outlet temperatures of the cold streams.

Minimize: $$C_{total} = C_{area} + C_{pump} \quad (3)$$

Subject to: $$\Delta P_t \le \Delta P_{max};\ \Delta P_s \le \Delta P_{max};\ r_d \ge r_{d,design};\ F_t \ge 0.75 \quad (4)$$

3 Particle Swarm Optimization

The proposed HEN synthesis problem is solved with Particle Swarm Optimisation (PSO). PSO is a stochastic optimisation technique developed by Kennedy and Elberhart (2001), inspired in the social behaviour of bird flocking or fish schooling. PSO as an optimisation tool provides a population-based search procedure in which individuals called particles change their position (state) with time. In a PSO system, particles fly around a multidimensional search space. During flight, each particle adjusts its position according to its own experience, and according to the experience of a neighbouring particle, making use of the best position encountered by itself and its neighbour.

In the last years, PSO has been successfully applied in many research and application areas. One of the reasons that PSO is attractive is that there are few parameters to adjust. In this work, it was used a PSO proposed by Vieira and Biscaia (2002). The particles and the velocity of each particle are actualized according to Eq. (3) and (4).

$$v_{k+1}^{(i)} = \omega_k v_{k+1}^{(i)} + c_1 r_1 \left(p_k^{(i)} - x_k^{(i)}\right) + c_2 r_2 \left(p_k^{global} - x_k^{(i)}\right) \quad (5)$$

$$x_{k+1}^{(i)} = x_k^{(i)} + v_{k+1}^{(i)} \quad (6)$$

Where $\boldsymbol{x}_k^{(i)}$ and $\boldsymbol{v}_k^{(i)}$ are, respectively, position and velocity vectors of the particle *i*, ω_k is the inertia weight, c_1 and c_2 are constants, r_1 and r_2 are two random vectors, $\boldsymbol{p}_k^{(i)}$ is the position with the best result of particle *i* and $\boldsymbol{p}_k^{global}$ is the position with the best result of the group. In above equations subscript *k* refers to the iteration number.

In a HEN synthesis problem, the variables considered independents are randomly generated at the optimization beginning and are modified in each iteration by the Eqs. (5) and (6). At the main optimisation, each particle is formed by the follow variables: fraction of hot stream splitting, fraction of cold stream splitting, number of stages and heat exchanged in each equipment. At the inner optimisation, each *particle* is composed by the variables: tube length,

hot fluid allocation, position in the TEMA table (that automatically defines the shell diameter, tube bundle diameter, internal and external tube diameter, tube arrangement, tube pitch, number of tube passes and number of tubes).

After the generation of the particle, the heat exchangers areas are calculated, as well as the hot and cold utilities demand. This is done to all particles even they are not a problem solution. The objective function value (global cost of the HEN) is obtained. If the particle is not a solution of the problem (any restriction is violated), the objective function is penalized.

The PSO parameters used in this work are presented in Table 1.

Table 1. PSO Parameters

4 Illustrative Example

An example, first used in Castillo et. Al (1998), is presented to illustrate the applicability of the proposed methodology. Six hot and five cold process streams are considered, as well as a hot and a cold utility. Streams, utilities and cost data are shown on Table 2. Physical properties of the streams and utilities and pumping cost data are not presented to the authors, so they are ficticious.

The value of the HEN global annual cost without the detailed heat exchangers design is 139,675 $/year. By applying the proposed methodology, the HEN cost is 152,120 $/year considering the pumping cost. The cost considering just the area and utilities cost is 137,466 $/year, that is smaller than that with no design is considered. The optimal network configuration obtained is presented in Fig. 1. Table 3 presents the details of the equipments design. Also, the designed heat exchangers are in accordance with TEMA standards. Table 4 shows the comparison with literature.

Area cost=9094 + 485$A^{0.81}$, A in m^2. Pumping cost = 0.7 ($\Delta P^t m^t/\rho^t + \Delta P^s m^s/\rho^s$), ΔP in Pa, m in kg/s and ρ in kg/m^3. Hot utility cost = 110 $/kW year. Cold utility cost = 15 $/kW year.

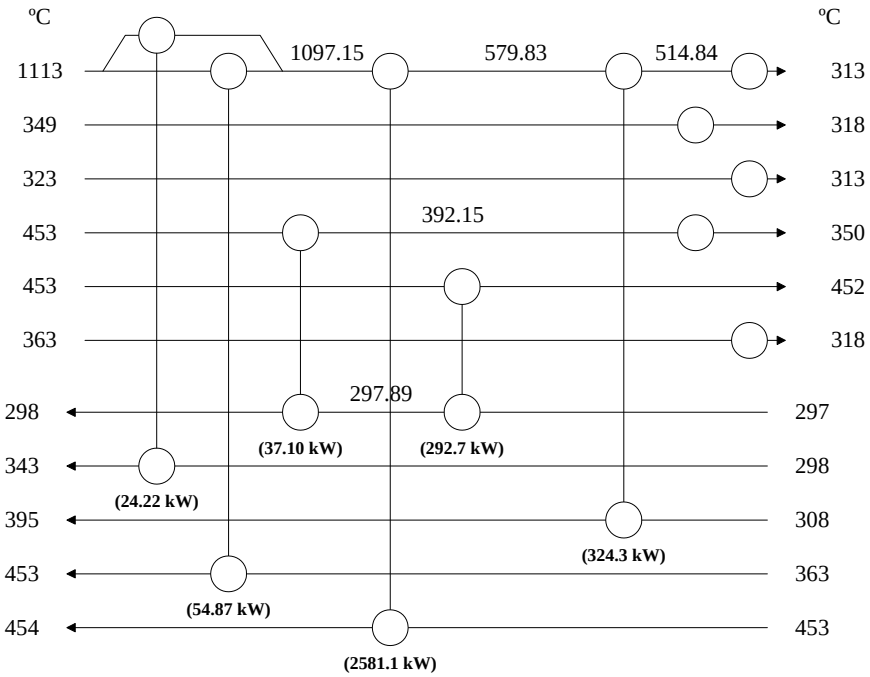

Figure 1 – Optimal HEN

5 Conclusions

In the present paper an algorithm for the synthesis of HEN including the detailed design of the equipments is proposed. It is based in a model similar to the stage-wise superstructure considering stream splitting and by-pass and a model for the optimal design of a shell and tube heat exchanger design, following rigorously the TEMA standards. The global annual cost objective function takes into account investment and utility costs.

An example were used to describe the algorithm applicability. The final results obtained in this paper are consistent with the presented in the literature and lower than those showed for Castillo et. al (1998) when considering no equipment design. The problem was optimised with PSO method, which is a reliable way compared with other methods, because it suits well to MINLP problems. Although with a very reasonable computational time of 540 minutes, the results are better and more realistic than the presented in literature.

Using Neural Network Predictive Control for Riser- Slugging Suppression

R. Eslamloueyan [*], **E. Hosseinzadeh** [†]
Petroleum and Chemical Engineering Department, Shiraz University, Shiraz, Iran

Keywords: Slug Flow, Neural Network, Nonlinear Model, Control Structure Design
Topic: Systematic methods and tools for managing the complexity (Process control & operations)

Abstract

Riser-slugging is a flow regime that can occur in multiphase pipeline-riser systems, and is characterized by severe flow and pressure oscillations. Reducing undesired slugging effects can have great economic benefits. Recently, control methods have been proposed to conquer slugging flow problems in pipeline risers. The advantages of using a control system are that it can be installed on existing oil and gas production facilities with no need to expensive equipment and that no significant pressure drop is imposed to the system.

In this work, a predictive control system based on Neural Network (NN) model of process is developed for handling and suppressing riser-slugging. An ANN model of the plant is used to predict future response of the nonlinear process. Storkaas dynamic model (Storkaas and Skogestad,2002) is employed for process simulation. Comparison of the results of this research to that of other works, indicates a significant improvement in setpoint tracking.

1 Introduction

Riser-slugging produce a cyclic variation of flow and pressure in pipeline risers. This phenomenon can be divided into four stages. At the first stage, slug begins to form because of low velocity of gas. During this period, the liquid is no longer carried over by the gas and begins to fall down and to make blockage in the riser bottom. The pipeline pressure increases until the liquid level in the riser reaches to the top. The second stage, which is called slug production, starts when the liquid level reaches the top of the riser, and the liquid slug is produced until the gas reaches the riser base. At the third stage, i.e. bubble penetration, gas permeates the liquid in the riser, so the hydrostatic pressure decreases and gas flow rate increases. The fourth stage is called gas blowdown. If the gas produced at the riser base reaches the top then the pressure is minimum and the liquid is no longer gas-lifted. The liquid downfall is repeated and a new cycle begins (Mokhatab et al.,2007).

The challenge of handling intermittent flow with liquid slugs followed by gas pockets in multiphase flow lines becomes more important when the number of production wells increases. Oil, gas and water are transported from the offshore wells through long pipelines (several kilometres) along the seabed and go up through a riser to the production platform. Slugging may have undesirable effects on the oil and gas production process. Severe slugging will cause fluctuations in the inlet separator liquid level. This may lead to poor separation or even in some cases to separator flooding. The oscillating pressure can increase the wear and tear in the processing equipment and will reduce the lifetime and increase the maintenance costs (Godhavn et al.,2005). Designing the topside facilities to tolerate these disturbances may involve large and expensive slug catchers as well as compressor packages with fast responding control systems. Hence, using a simpler

[*] Fax:+98-711-6287294 , Email: eslamlo@shirazu.ac.ir ; reslamloueyan@yahoo.com
[†] E-mail: elham_hosssienzadeh@yahoo.com

preventive system to alleviate or eliminate severe slugging phenomenon becomes very essential. Control systems have been widely proposed to tackle the slugging problem in pipeline risers. For a complete review of current technologies for severe slugging remediation, see Mokhatab et al. (2007).

Fard et al.(2003) show that a cascade-control strategy with feedback from bottom pressure and flow rate at the top of the riser is adequate to suppressing the slugs. However this control strategy requires pressure measurements at the bottom of the riser. Storkaas and Skogestad (2002) developed a simple dynamic nonlinear model for riser-slugging in pipeline-riser system and presented controllability analysis and conventional controller design for linearized model around equilibrium point. Hardy B. Siahaan proposed a state feedback design method for attenuating severe slugging in multiphase flow pipeline-riser systems. The algorithm is designed based on the input output linearization method, and incorporates the saturation effect on the input. The designed state feedback can suppress the slugging phenomenon provided some conditions are satisfied.

The nonlinearity of the slugging cycle in pipeline risers can motivate researchers to use nonlinear model based controllers. Nonlinear model predictive control (NMPC) allows direct consideration of a nonlinear process model as well as state and input constraints. Thus NMPC seems to be well suited for this kind of processes. MPC have been used for control of various systems including process industries (Findeisen et al., 2001; Majanne, 2005). The term MPC does not specify a specific controller but a wide range of control strategies which use a model of process to obtain the optimum values of manipulated signals by minimizing an objective function. Most predictive control algorithms are based on a linear model of the process. However, industrial processes usually contain complex nonlinearities and a linear model may be acceptable only when the process is operating around an equilibrium point. If the process is highly nonlinear a nonlinear model will be necessary to describe the behaviour of the process. Recently, neural networks have been used in some predictive control algorithms that utilize nonlinear process models. In this work, the process model of the proposed MPC is a non stationary neural network with one hidden layer. The following section is devoted to the process model and Neural Network MPC method.

2 Process Model

A simple nonlinear model with only three dynamic states was developed by Storkaas and Skogestad (2002) to simulate the dynamic behaviour of slug formation in pipeline risers. This model covers both riser-slugging, and, more importantly, the unstable but preferred non-oscillatory flow regime that exists at the same boundary condition. Conservation equations are given in equation 1.

$$\begin{aligned} \frac{d}{dt} m_L &= \dot{m}_{L,in} - \dot{m}_{L,out} \\ \frac{d}{dt} m_{G_1} &= \dot{m}_{G,in} - \dot{m}_{G_1} \\ \frac{d}{dt} m_{G_2} &= \dot{m}_{G_1} - \dot{m}_{G,out} \end{aligned} \tag{1}$$

The three-state model is well suited for analysis and controller design because of its limited complexity and its ability to predict the essential system characteristics for control purposes, and can be used for designing anti-slug controllers. Figure 1 illustrates pipeline-riser system at the situation of riser-slugging. The model has only three dynamic states: the gas and liquid holdups in the riser (i.e. m_L, m_{G_2}), and the holdup of gas in the upstream pipeline(m_{G_1}).The most important adjustable parameters are the ”valve constant” for the flow of gas into the riser and two parameters describing the fluid distribution in the riser. For the details of modelling see Storkaas and Skogestad (2002).

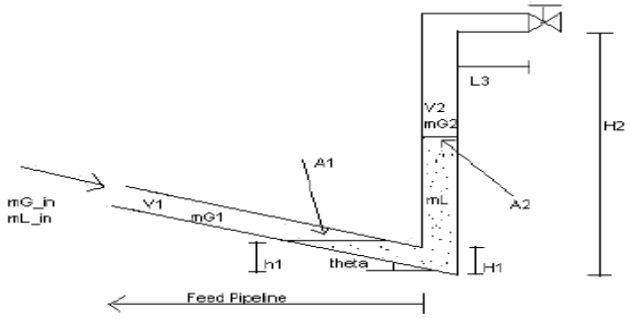

Figure 1- Illustration of pipeline-riser system

3 NN Predictive Controller Design

Neural networks have been applied very successfully in the identification and control of dynamic systems. The universal approximation capabilities of the multilayer perceptron make it a popular choice for modelling nonlinear systems and for implementing general-purpose nonlinear controllers. The progress in computer technology has made a significant advancement in neural network research. Artificial neural network (ANN) is an mathematical expression of the neural aspect of the human brain. The process of learning in ANN's is based on experience and repetition rather than the application of rule-based principles and formulas. ANN provides capabilities such as learning, self-organization, generalization (response to new problems using incomplete information), and training (Hagan et al.,1996).
Two steps are carried out when using neural networks for control:
- System Identification
- Control Design

In the system identification step, a neural network model of the plant is developed. In the control design stage, the neural network model is used to design (or train) the controller.

For the model predictive control, the plant model is used to predict future behaviour of the plant, and an optimization algorithm is used to select the control input that optimizes future performance. The fundamental idea in predictive control is to predict the vector of future tracking errors and minimize its norm over a given number of future control horizons. It is therefore clear that predictive controller design mainly consists of two parts: prediction and minimization. An optimization algorithm computes the control signals that optimize future plant performance. The neural network plant model is trained offline, using one of the training algorithms based on backpropagation.The controller, however, requires a significant amount of on-line computation, since an optimization algorithm is performed at each sample time to compute the optimal control input.

3.1 System Identification

The first stage of model predictive control is to train a neural network to represent the forward dynamics of the plant. The prediction error between the plant output and the neural network output is used as the neural network training signal. The process is represented in figure 2. A neural network consists of layers of simple processing units coupled by weighted interconnections. The neural network plant model uses previous inputs and previous plant outputs to predict future values of the plant output. The structure of the neural network plant model is given in figure 3.

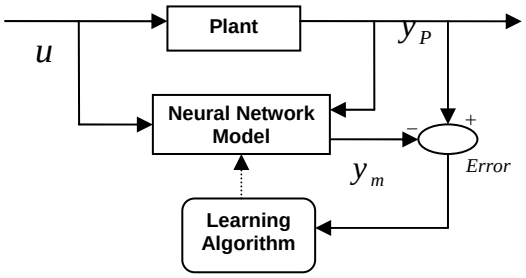

Figure 2- System identification with neural network

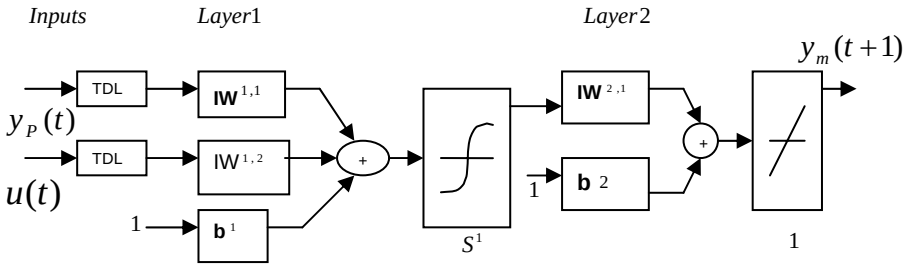

Figure 3- Structure of the neural network plant model

This multi layer perceptron (MLP) network can be trained offline in batch mode, using data collected from the operation of the plant. Any of the training backpropagation algorithms can be used for network training.

The plant model neural network has one hidden layer with 7 neurons. Levenberg-Marquardt algorithm was used for training the network. The application of Levenberg-Marquardt to neural network training is described by Hagan et al. (1996). Tangent sigmoid transfer functions were selected for neurons. The required training data was generated by by applying a series of random step inputs to the process simulation.

3. 2 Predictive Control

The model predictive control method is based on the receding horizon technique (Soloway and Haley,1996). The neural network model predicts the plant response over a specified time horizon. The predictions are used by a numerical optimization program to determine the control signal that minimizes the following performance criterion over the specified horizon.

$$J = \sum_{j=N_1}^{N_2} (y_r(t+j) - y_m(t+j))^2 + \rho \sum_{j=1}^{N_u} (u'(t+j-1) - u'(t+j-2)) \quad (2)$$

Where N_1, N_2 and N_u define the horizons over which the tracking error and the control increments are evaluated. The variable u' is the tentative control signal, y_r is the desired response and y_m is the network model response. The value ρ determines the contribution that the sum of the squares of the control increments has on the performance index. Figure 4 illustrates the block diagram of the model predictive control process. The controller consists of the neural network model and the optimization block. The optimization block determines the values of u' that minimize J, and then the optimal u is input to the plant. Backtracking technique was used as a linear search routine for optimization algorithm. It searches in a given direction with search parameter α to locate the minimum of the performance function in that direction (Dennis et al., 1983).

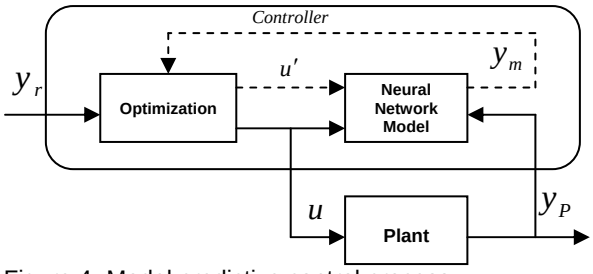

Figure 4- Model predictive control process

The controller horizons N_2 and N_u. (N_1 is fixed at 1, $N_2 > N_u$) and weighting parameter can be defined based on optimization algorithm.

4 Results

As shown in Fig. 5, the control objective is to maintain flow regime at desired condition to avoid pressure oscillations by manipulating the valve opening at top of the riser. The controlled variable is P1, the pressure of feed-pipeline, and the manipulated variable is the percentage of valve opening.

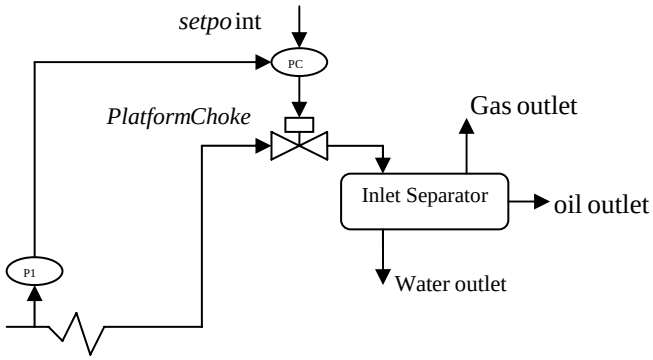

figure5- control structure with feedback from pressure at the bottom

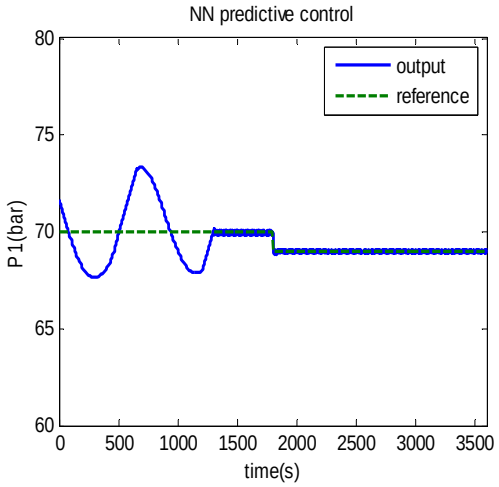

Figure 6- simulation result for NN predictive control

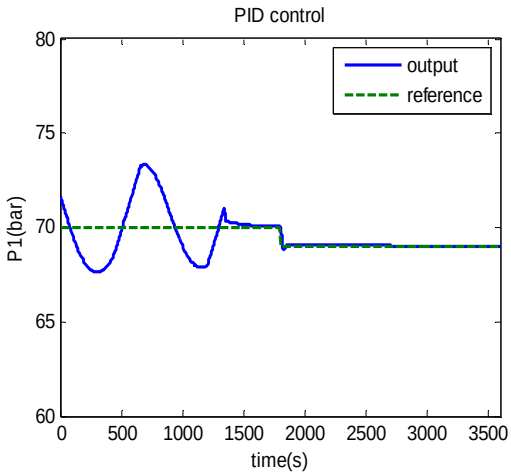

Figure 7- simulation result for PID control

The closed loop responses of the developed NN-MPC and a conventional PI controller are indicated in Fig. 6 and 7 respectively. The controllers are triggered after 1200 seconds and a unit step decrease in reference signal is introduced after 1800 seconds. The tuning parameters of Storkaas were used for the PI controller. In another scenario, while both controllers are active, a unit step change in reference signal is introduced after 60 seconds. Figures 8 and 9 illustrate the responses of the controllers in this case.

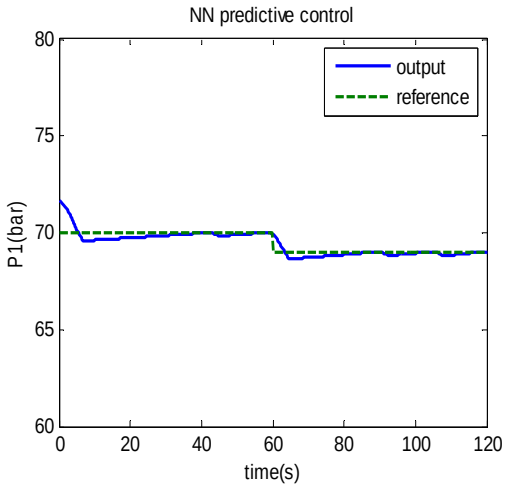

Figure 8- detailed result for NN predictive control

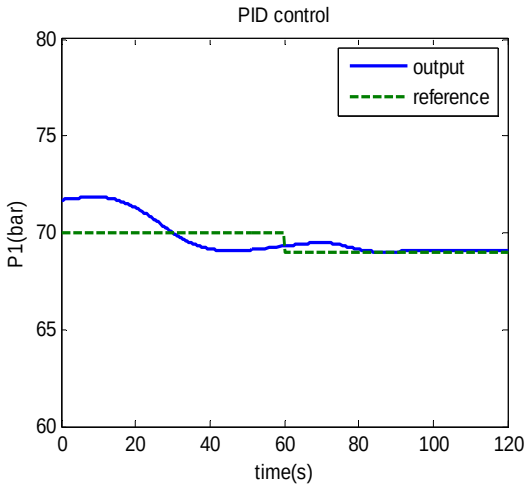

Figure 9- detailed result for PID control

The integral of absolute errors (IAE) for the NN MPC and the PI controller are respectively, 22.9 and 72.6. Figures 6-9 and IAE performance index indicate that the response of NN MPC is considerably better than that of the PI controller.

5 Conclusion

This paper introduced NN predictive control for handling flow regime in pipeline-riser systems to avoid riser-slugging phenomenon. In comparison with conventional control, NN predictive control acts early with better set point tracking. Simulation proved that in case of higher step change or reversing the change direction, the capability of the developed NN predictive control in comparision to the PI controller becomes much more apparent.

Topic: Integration of life sciences & engineering

Abstract: This paper presents an approach of artificial neural networks to predict the sensorial quality of wines. A Kohonen network has been used as a software tool in order to increase the human skills in this kind of application. An initial prototype was implemented using the artificial neural networks technology, together with the Visual Basic software from Microsoft, for evaluation of sensorial qualities of seven samples of acerola (*Malpighia glabra* L.) wine. 50 consumers chosen to perhaps had been used to obtain the sensorial data using a hedonic scale of 1-9 times. Sensorial values of flavor, aroma and appearance obtained of the hedonic dating were compared. The characteristic of wine, as flavor and color were similar to the acerola fresh fruit. The consumers evaluated the wines as very good, all sensorial qualities were more than 5 in hedonic scale. Results showed that Kohonen network classified the acerola wines in distinct group, for frequency among yours sensorial responses. Kohonen network results were similar or better than statistical classification, this shows that the use of Kohonen algorithm in the sensorial analysis of wines is valid. Kohonen algorithm is very good in clustering of acerola wine samples and it uses in sensorial analyses of wines is promises.

1. Introduction

The wine commercialization undergoes long and traditional trajectories until it arrives at the table for consumption. However, the product undergoes stabilization treatments and packaging that transforms it into a quality product although at many times, turns it to be quite original and personalized. Thus being, the wines should constant improvements in its characteristics and these must be perfectly stabilized and submitted to severe rules which assure product protection against frauds, whereby guarantee the consumer (Delanoe et al., 1989).

Although the wines better appreciated are made from grapes yet other fruits could be utilized as raw material for the manufacture of wines. These fruits could be orange, pineapple, strawberry, acerola, cashew apple and other exotic fruits such as cupuacu (Freitas et al., 2001; Garrutti, 2001). Generally, the wines made from these fruits result in flavor and aroma characteristics of the original fruit utilized and if due care is taken, could last for long time storage.

Evaluations of sensorial analysis are made, commonly, by statistical methods. These methods are wide used to evaluate the consumer acceptance on the food qualities, as: the appearance, aroma, color and flavor of several products. In fruit wines these methods had be also applied. Costa et al. (2006) had made a sensorial analysis with 30 consumers to compare statistically the

* Author for correspondence, E-mail: eliastam@feq.unicamp.br Phone: 55+19+35213952

wine from cashew apple (*Anacardium occidentale* L.) against the peach and grape wines. Severo Júnior et al. (2007) had made the statistical sensorial evaluation of wines produced from cajá (*Spondias mombin L.*) pulp; to evaluate the effects of clarification methods, one by sedimentation and other by membrane separation process.

Artificial neural networks technology had been applied in simulation and optimization of several industrial processes (Kohonen, 1989). Actually, Kohonen algorithm was applied to help in the pediatrics diagnosis area, considering particular issues noticed in newborns and suckling, usually with non-specific clinical trial (Dias and Radonsky, 2003). This paper presents an approach of artificial neural networks to predict the sensorial quality of wines. A Kohonen network has been used as a software tool in order to increase the human skills in this kind of application. An initial prototype was implemented using the artificial neural networks technology, together with the Visual Basic software from Microsoft, for evaluation of sensorial qualities of seven samples of acerola (*Malpighia glabra* L.) wine.

2. Material and Methods

2.1 Preparation of Must

The acerola fruit at stage of maturity were selected, cleaned with chlorine (2 ppm of active Cl_2) water and triturated in mixer, thus obtaining the pulp which was stored in a refrigerator. For the preparation of must, the pulp quantity of acerola fruits and total soluble solids (°Brix) content were varied according to the experimental planning design of 2^2, presented in Table 1. The inorganic nutrients were added in the concentrations of 1 g/L of $NH_4H_2PO_4$ and 0.1 g/L of $MgSO_4$. The pH of the medium was later corrected in the range of 4 to 5 with Na_2CO_3. Fractions of total volume of these were separated in different flasks, from the principal vat as being to approximately 4 L, 500 ml and 10 ml, which were denominated as vessels. These were pasteurized by heating in an autoclave and cooling rapidly in running water having the sole objective of sterilization of medium (Delanoe et al., 1989; Garruti, Evangelista et al., 2005; 2001).

In order to better evaluate the effect of total solids (°Brix, g sugar/l00 mL of must) and fruit pulp mass (%Mass, kg acerola pulp/ liter of must) on the wines acceptability in relation to flavor, color and aroma.

Table 1. Experimental conditions of manufacture of acerola wines.

Wine samples	Factors	
	°Brix (g sugar/100mL)	% Mass (kg acerola pulp/liter of must)
A	22	1/6
B	26	1/6
C	22	1/3
D	26	1/3
E	24	¼
F	24	¼
G	24	¼

2.2 Preparation of wines

Fermentation: the yeast *Saccharomyces cerevisiae* was inoculated in the lowest volume of vessel at a concentration of 70 to 80 g/L, where it remained between 20 - 24 h for adaptation of the medium. It was later transferred to the next vessel and maintained for 48 h, after which it was transferred to the principal vat, in which it remained for the final days of its fermentation. After fermentation, the wines were clarified by added of bentonit clay at 1% solution. Later

filtration for complete separation of the two phases (liquid and solid) was achieved, resulting in a clear wine (Delanoe et al., 1989; Garruti, 2001; Lima et al., 2001). The wines were packed in amber-colored bottles of 1.0 L capacity which were sealed with cork. The closed wine bottles were pasteurized by heating in an autoclave at 115°C and 1.5 kg/cm^2 for 15 min, cooled later in running water and stored in refrigerator at 5°C for a period of 6 months for posterior evaluation of its quality (Gava, 1986).

2.3. Sensory analyses

The acceptability of samples of fermented musts were evaluated using sensory affective tests, comparing with the aroma of sparkling wine. The samples were served to the 50 consumers in codified tulip-shaped glasses covered with watch glasses, using a monadic presentation and a hedonic scale distributed on 9-times. The consumers also registered their purchasing intentions for each sample on the same score sheet, using a five-point attitude scale (Mamede et al., 2005; Teixeira et al., 1987). Sensorial characteristics such as flavor, color and aroma of wines were evaluated. The experimental research on quantitative basis was undertaken wherein a standard form for sensorial analysis was used and random sampling was applied for each of the above attributes using a hedonic scale (1-9 times). Based on frequency of responses, the sensorial data were compared by average values and Kohonen neural network.

2.4. Wine classification by Kohonen algorithms

An initial prototype was implemented using the artificial neural networks technology, together with the Visual Basic software from Microsoft, for evaluation of sensorial qualities of seven samples of acerola (*Malpighia glabra* L.) wine. Similarities among wine samples were classified into groups by Kohonen algorithms. The sensorial values attributed by consumers to the same wine samples were cataloged in tabled form, as it showed in Table 2. The subscript index ap, ar and fl are corresponding respectively to the appearance, aroma and flavor sensorial qualities from A, B, C, D, E, F and G wine samples. The Kohonen neural network makes a screen of the lines and columns of this table, clustering the sensorial values of one sample against the sensorial values of other samples (Dias and Radonsky, 2003; Kohonen, 1989).

Table 2. Example of the weight distribution (Wn) to screen of sensorial values by Kohonen neural network.

Samples	W1	W2	…….	W50
Aar	2	9	.....	9
Bar	3	8	.....	7
Car	4	7	.....	8
Dar	5	6	.....	8
Ear	6	5	.....	2
Far	7	7	.....	3
Gar	8	6	.....	1

3. Results and Discussion

The wines obtained in this work had color, aroma and flavor characteristics from acerola fruit and it was classified as suave. Its alcoholic gradation was approximately 11 °GL and had all other physical-chemical characteristics within the norms specified by Brazilian legislation.

The sensorial analysis demonstrated that there was no significant difference among the various wines manufactured and their mean acceptance was about 6 point. It showed that the wines

which were produced with the must of higher °Brix and lower quantity of pulp mass were more acceptable by panel members.

Figure 1 shows the results obtained for clustering of the sensorial quality, appearance. Sensorial values for some wine samples after comparison were grouping by similarity via Kohonen neural network and its average values (statistic method). It notes that the groups obtained by Kohonen methods are identical to the statistical method group.

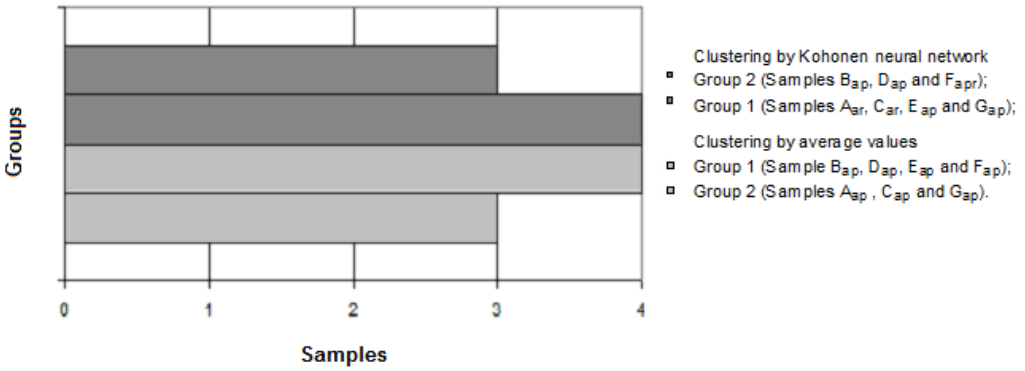

Figure 1. Classification for grumping by the similarity among wine samples; for the appearance sensorial quality.

Figure 2 shows the results obtained for clustering of the sensorial quality, flavor. It notes that Kohonen neural network had obtained four groups and statistical method (average values) only three groups. Kohonen neural network had find difference among the samples of statistic Group 2; and re-grouping in two new Groups (Kohonen Group 2 and 4). This occurred due to Kohonen algorithm found smaller differences among samples. Also, there were similarities among Kohonen Group 1 to the statistical Group 3 and Kohonen Group 3 to the statistical Group 1; and difference among the others.

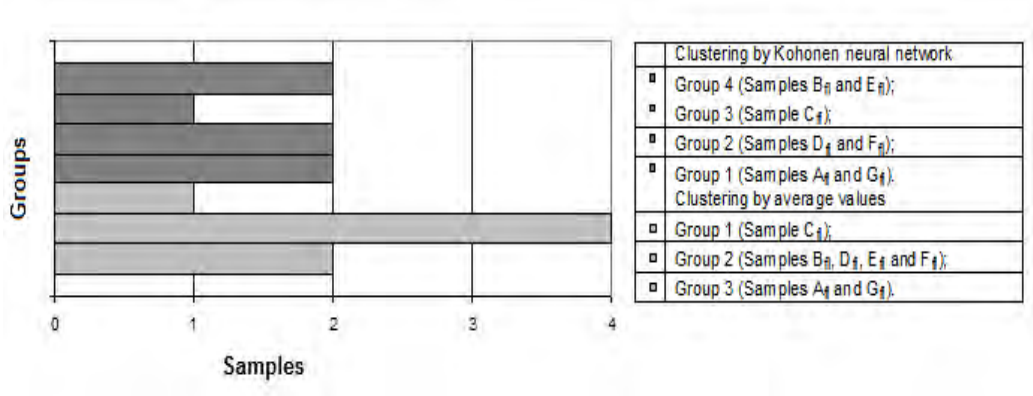

Figure 2. Classification for grumping by the similarity among wine samples; for the flavor sensorial quality.

Figure 3 shows the results obtained for clustering of the sensorial quality, aroma. It notes that Kohonen neural network had obtained three groups and statistical method (average values) only

two groups. Kohonen neural network had find differences among all statistical Groups. From statistical Group 1, Kohonen neural network had separated E_{ar} sample in one Group (Kohonen Group 3); from statistical Group 2, Kohonen neural network had separated Aar, while it was grouping in Kohonen Group 1. The other samples were similar. It emphasizes that Kohonen neural networks can be evaluate a conjunct of great quantities of values and finding differences among its samples; this is torn a good tool to clustering of beverage samples by sensorial comparison.

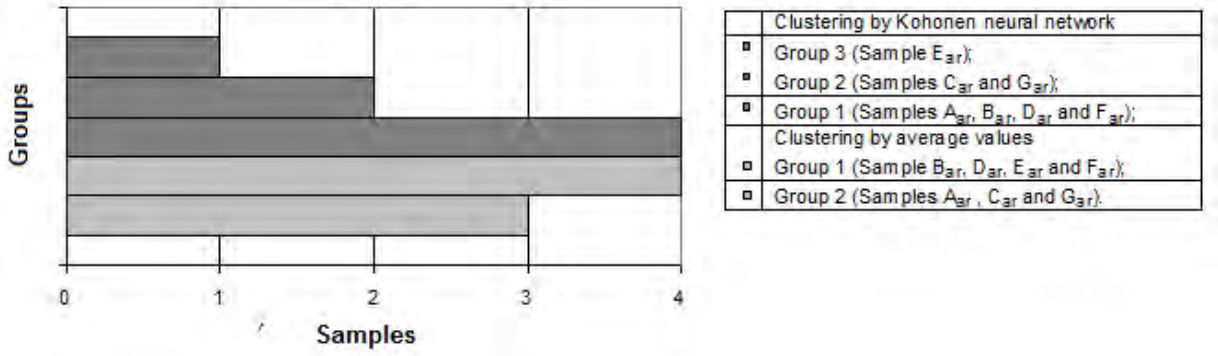

Figure 3. Classification for grumping by the similarity among wine samples; for the aroma sensorial quality.

4. Conclusions

The wines obtained in this work had color, aroma and flavor characteristics of acerola and it was classified as suave. Its alcoholic gradation was approximately 11 °GL and had all other physical-chemical characteristics within the norms specified by Brazilian legislation. Their mean acceptance was about 6 point in hedonic scale. Wines which were produced with the must of higher °Brix and lower quantity of pulp mass were more acceptable by panel members.

Kohonen network classified the acerola wines in distinct group, for frequency among yours sensorial responses. Kohonen network results were similar or better than statistical classification, this shows that the use of Kohonen algorithm in the sensorial analysis of wines is valid. Kohonen algorithm is very good in clustering of acerola wine samples and it uses in sensorial analyses of wines is promises.

Topic: Systematic methods and tools for managing the complexity

Abstract

The feasibility to use an extractive distillation process to replace liquid-liquid extraction unit (Arosolvan) at Galp Energia plant in Leça da Palmeira was studied. The simulations were performed using Aspen Plus® simulation modules, and NRTL model was used to predict thermodinamic data. Simulation results allowed to conclude that aromatics recovery increases comparatively to actual operation data. An economic study was performed determining the investiment and operating costs.

Introduction

Nowadays, Chemical and Petrochemical industries are facing a growing need for cheaper and higher quality raw materials. Aromatic compounds, such as benzene and toluene, are examples of such important feedstocks. Traditionally, these substances are produced from petroleum distillation cuts by liquid-liquid extraction, which was, for many years,the first choice for the mentioned industries to recover aromatic compounds, due to the fact that the available solvents were not suitable for the separation processes based in extractive destillation.

However, the technology for producing new solvents has suffered an improvement and the availability of new solvent mixtures makes more profitable the implementation of extractive distillation for aromatic recovery.

Extractive distillation is the state of art of distillation since it allows to optimize the production and purity of the required products at low operation costs. The main difference between this technology and liquid–liquid extraction is the addition of a third component, a highly selective solvent that changes the separation caracteristics between the substances by increasing relative volatility values.

Aromatics can be produced through the reformate, which is a mixture of aromatic and aliphatic hydrocarbons. This is a complex and very difficult mixture to separate in different compounds due to the existence of components with volatility nearly the same as azeotropic components. In extractive distillation the addition of a solvent alters the relative volatilities of the components, thus increasing the difference between them and thereby promoting their separation (Wankat, 2007). These interations occur mainly in the liquid phase, being the solvent continuosly added close to the top of the extractive column, allowing that a significant amount is present in the liquid phase on all trays. The reformate is added near the middle of the column and the component with greater volatility (non-aromatic compounds) is taken overhead as a quite pure distillate. This causes the solvent to go downwards in the column while the non-aromatics travels upwards, and on each tray both phases are closely contacted and re-separated as shown in Figure 1.

Non-aromatic compounds are removed on the top of the column and condensed, constituting the raffinate product. A portion of the condensate liquid is refluxed to the column and this reflux determinates also the ratio of separation. The aromatics and the solvent leave

the bottom of the column and are sent to the solvent recovery column. In this column the aromatics are separated from the solvent by a simple distillation process. Aromatic vapors from the solvent recovery column are condensed and this liquid is the extract product. The bottom product of this column is aromatic-free solvent and returns to the extractive distillation column, passing through an heat exchanger. The efficiency of the solvent recovery column is a very important factor, not only because of the quantity and purity of the produced aromatics, but also because of the recovered solvent. This allows to minimize the fresh solvent needs (Ko *et al.*, 2002).

Beside the improvement of new solvent production technology, extractive distillation systems now use better heat integration, enhanced mass transfer devices, as a way to maximize production capacities with reduced operation costs and lower environmental impacts.

The purpose of this project was to verify the aplicability of extractive distillation in Arosolvan Unit at the Aromatics Plant of Leça da Palmeira's refinery (Galp Energia), using Aspen Plus® simulator. A comparison between simulator and operating data from the refinery was also performed.

Following this study, an economic analysis was performed, to assess the investment needed in the replacement of the liquid-liquid extraction plant by a extractive distillation unit. The number of years of return of investment was also determined.

Simulation

The implementation of a extractive distillation process begins with the choice of an appropriate solvent. The parameters to consider are its selectivity, stability and toxicity, cost effectiveness to use in commercial operation and compatibility with plant operations. After a literature review, the solvent Sulfolane was chosen. This solvent is already used by UOP company (www.uop.com) and it has the particularity of promoting a good separation at acceptable costs for an industrial application (Choi *et al.,* 2002).

Sulfolane solvent was developed in the early 1960's but it still remains as one of the most efficient solvent available for aromatics recovery. Studies (Gentry *et al.*, 2004) made, using this solvent to separate the binary mixture C-7/benzene, which is a rough approach to the feed conditions, revealed that it alters the relative volatility of the components by a margin large enough to obtain a successful result. This solvent is easy separable from the bottom product and doesn't react chemically with none of the components in the reformate, or causes corrosion in the equipment.

The extractive distillation was designed and simulated using Aspen Plus® simulator, one of AspenONE ™ Process Engineering modules, developed by AspenTech. The thermodynamic model used was the Non-Random-Two-Liquid (NRTL), found to give a better aproach to a real system (Ko *et al.*, 2002).

The basic configuration of a extractive distillation process, as shown in Figure 1, requires two separation columns, while the existing liquid–liquid extraction unit (Arosolvan) has three columns.

The first column is the Extractive Distillation column, where the separation between the aromatics and non-aromatics occurs. The second column is the Solvent recovery column, where the separation of the solvent from the aromatics occurs, producing the main product and clean solvent.

As a way to design the extractive distillation column, Distl and DSTWU models were used. These two models are used in simple distillations, differing only in the method of calculation, the first one uses the Winn-Underwood-Gilliland method and the second one the Edmister method. Both models consider one column with just one feed and two exit products, as well as a total or partial condenser.

Thereby, the DSTWU model was used to estimate the operating conditions and on the basis

of these results we simulated the desired conditions in RadFrac model.

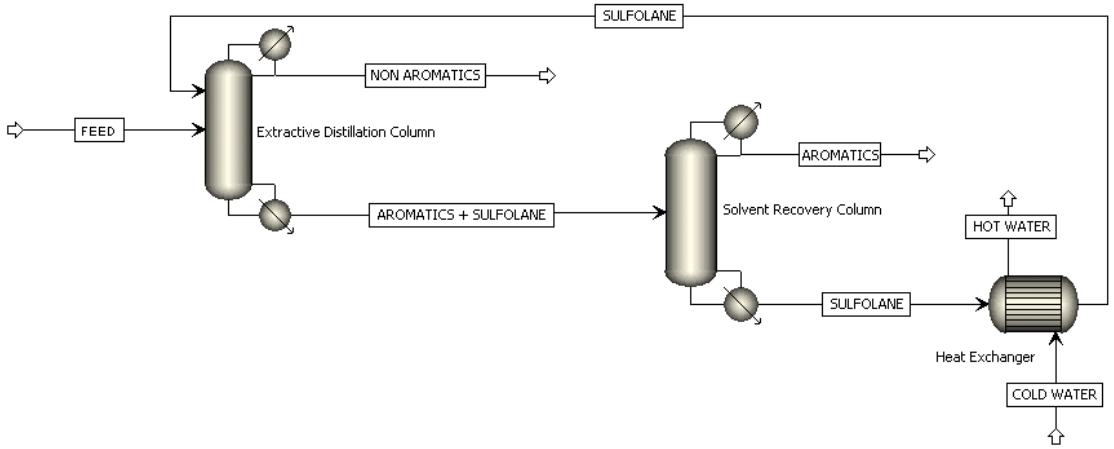

Figure 1 – Flowsheet of the extractive distillation unit, with *Sulfolane* solvent.

The feed conditions were defined based on data obtained from Galp Energia plant, and after several simulations the extractive distillation column which presented the best results was a column with 40 stages and a reflux ratio of 1.4.

In this type of simulation, the operation conditions on the column can be predicted, as well as the composition of the exit products. This data can be recovered through the program report, however all the informations are available on the Aspen Plus result window.

In these simulated conditions, the reboiler needs 14133 kW of power consumption, at 418.2 K and 0.431 mass reflux. It was selected a total condenser, which needs 5152 kW of cooling power at 372.2 K, and 1.4 reflux ratio.

One of the factors related to the power needs of the reboiler and the condenser is the reflux ratio. When the reflux ratio increases, the power needs of the two equipments also increases. The higher the reflux ratio used, the greater the amount of liquid introduced, increasing the need of energy at the reboiler. Furthermore, the greater the amount of liquid added, the greater will be the production of vapor at the top of the column, increasing the energy needed by the condenser.

The RadFrac model estimates, for each stage, the molar and mass volumes of the liquid and vapor, plus the temperature and composition profiles of the components in the mixture.

Figure 2 shows the mole fraction profiles of the components in the liquid phase for the extractive distillation column. The Sulfolane composition suffers two major changes near stages 5 and 10, where the feed enters. With the exception of these two points, the proportion of solvent remains constant. While these changes occur in Sulfolane composition, it can be verified that the n-heptane changes its physical state, passing from the liquid phase to the gas phase. On the other hand, benzene and toluene profiles are graphically similar, as expected, because they leave the column together.

As it can be seen in Figure 3, there is no Sulfolane in the vapor phase along the entire column. The changes in the profiles occur after the introduction of the feed and solvent streams. The top stream of the column consists essentially of n-heptane, while the bottom stream of the column is rich in benzene, toluene and Sulfolane

The Solvent Recovery Column was designed following the same methodology of the extractive distillation column, originating similar charts to previous ones (Figure 2 and 3). For this column the best results were obtained with 30 stages and a reflux ratio of 1.2. The reboiler and condenser's conditions are shown in Figure 4.

Aspen Plus doesn't give only the information about the power needs for the equipment, but

also gives information about the composition and physical properties of the liquid and vapour at any stage. From the computed results, the aromatics recovery was calculated and compared to actual data from the refinery. Table 1 shows the recovery fractions.

Table 1 – Recovery fractions.

Compound	Total Recovery [%]	
	Actual	Proposed alterations
Toluene	90,026	99,996
Benzene	88,215	99,339
N-heptane	57,062	99,138

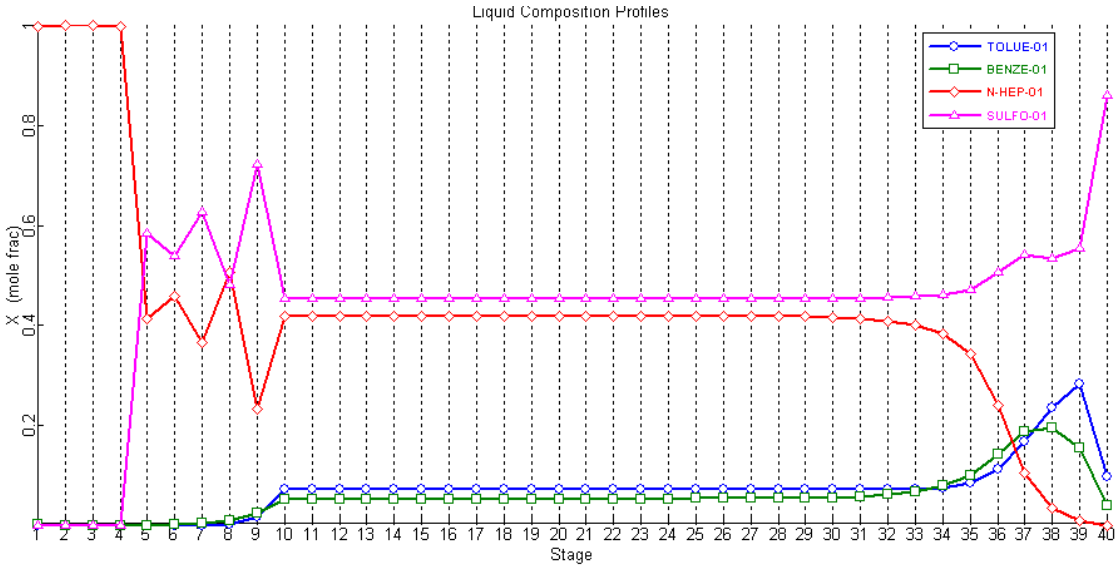

Figure 2 – Liquid composition profilles of the Extractive Distillation Column.

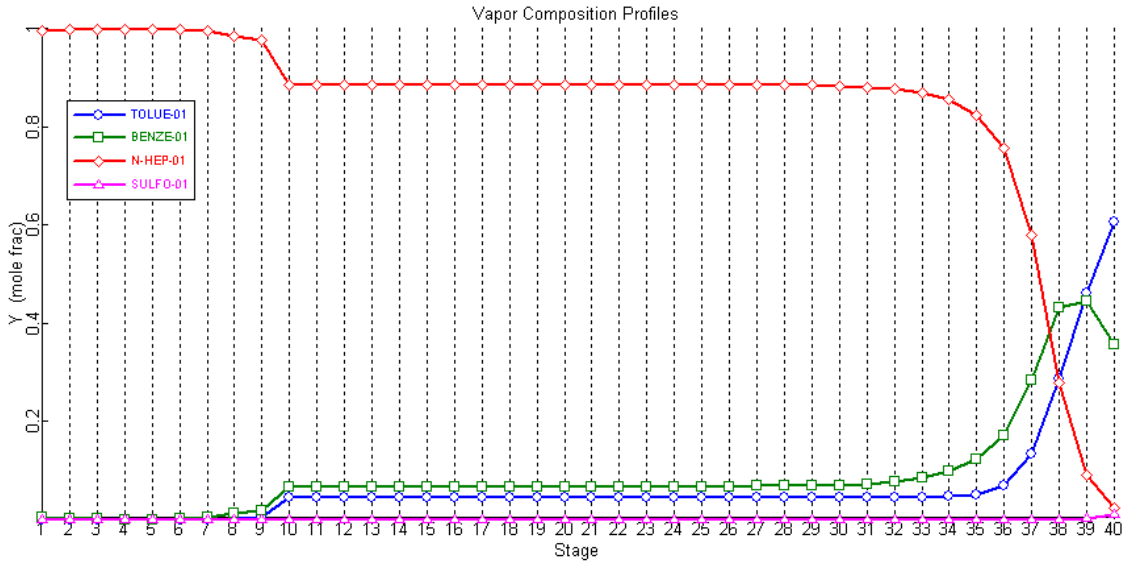

Figure 3 – Vapor composition profilles of the Extractive Distillation Column.

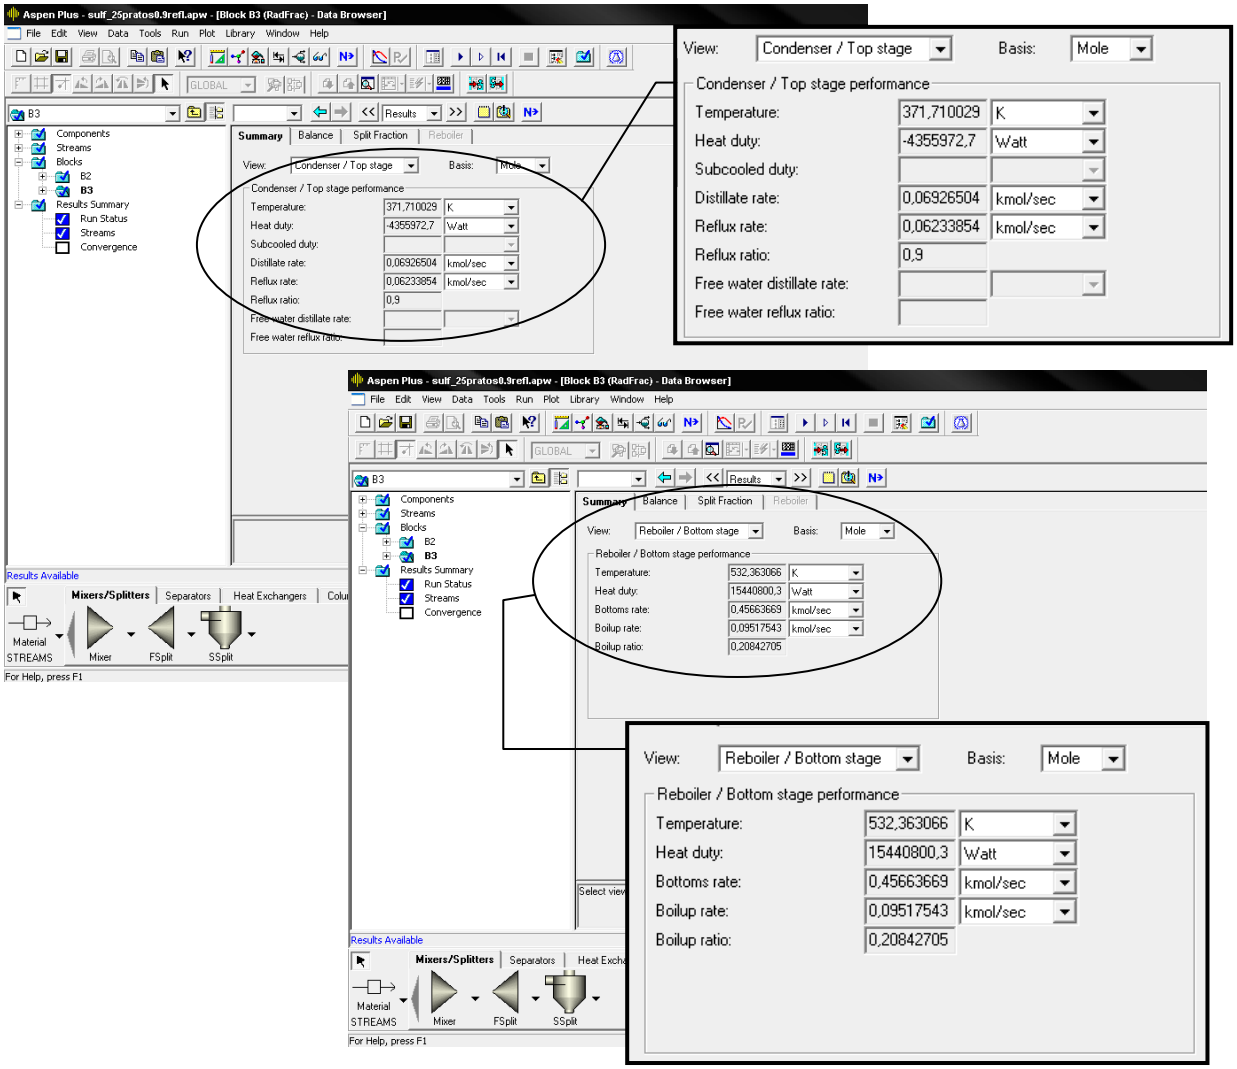

Figura 4 – Window of the Aspen Plus simulator, with reboiler and condenser's operating conditions.

In order to complete the study of this unit, the transfer area needed in the heat exchanger was determined, resulting in the value of 275 m^2.

An economic study was conducted, taking into account the necessary equipment, operating costs and the profits due to the achieved improvements, and considering a discount rate of 10%.

To implement the extractive distillation unit, and taking into consideration the existing plant, it was necessary to acquire only one new column. The real size of the columns, was calculated taking into account that the trays implemented would have an efficiency of 80%.

The operating costs were determined considering the expenditure necessary to ensure a year production and the energy consumption associated to the process.

The main profits of this project come from the additional amount of benzene and toluene which will be produced.

Therefore, after the necessary calculations, it was determined that for a facility with this scale it will be required around 6 000 000 euros (values referred to 2007), resulting in a return of capital employed of 5 years.

Conclusions

The extractive distillation process has many advantages compared to liquid-liquid extraction process. The basic configuration of liquid-liquid extraction requires four units, while extractive distillation only needs two, making the investment costs lower in ED. Apart from using new solvent formulas, the extractive distillation system uses also better heat integration. Another advantage is the improvement of the operation conditions, leading to an enhanced control of the system.

The Sulfolane process was simulated with Aspen Plus, a sequential modular simulation software, using NRTL model. With the proposed process we achieved a 99% compounds recovery with a total investment amounting to 6 000 000 euros (values refered to 2007).

Topic: Systematic methods and tools for managing the complexity

Abstract

Image processing is a very relevant area of computer science with applications in many domains. Quantitative analysis and interpretation of digitized images is currently an important tool in several scientific domains.

Namely in multiphase systems modelling in Chemical Engineering, the acquisition and treatment of images of particulate phases become essential for the calculation of particle size and shape distributions. In the modelling of liquid-liquid systems these are of major importance either for hydrodynamic and mass transfer (with or without chemical reaction) modelling and validation. From these arise simulation, interpretation and performance predictions of multiphase reactors

Often, such a treatment is undertaken by visual/manual techniques which imply high costs, intensive labour, weariness build-up and consequent high error rates, while a fully automated computational approach has a definite potential for better performance.

The aim of the present work is the development of shape discrimination and size classification algorithms for liquid drops in monochromatic digitized frames.

1 Introduction

Image frames were obtained at our SIPROM (Modelling and Simulation of Multiphase Systems) Laboratory with a digital video camera + microscope + illumination set-up from a dispersion of toluene in water within a transparent mixing vessel (Ribeiro, 2002).

Experimental conditions (mainly phase ratio and agitation speed) led to frames of deeply focused fields with partially overlapping drops and high background noise, as we can see in Figure 1. In this figure we show two images, the first one is what we consider a better quality image whereas the second image is very difficult to process. Since non-invasive image acquisition and lighting were our uncompromising starting option, no significant improvements were obtained although all available image acquisition and cleaning techniques were used within this fundamental constraint. Thus, partial images and ill-defined drop boundaries led to all low-cost, market-available image processing software packages requiring a high number of frames in order to secure statistically significant drop samples which, again, made for greatly time-consuming, unreliable procedures.

* Corresponding author. Tel + 351-228340500. E-mail:efg@isep.ipp.pt

This led us to develop our own software for which a preliminary test and calibration stage was performed on archive images previously obtained with a semi-automated procedure (Ribeiro et al. 2004). We have developed a promising approach, implemented in *Matlab*, which, given one of these photographic images of a dispersion, automatically identifies the contour of existing drops and classifies them according to their diameter.

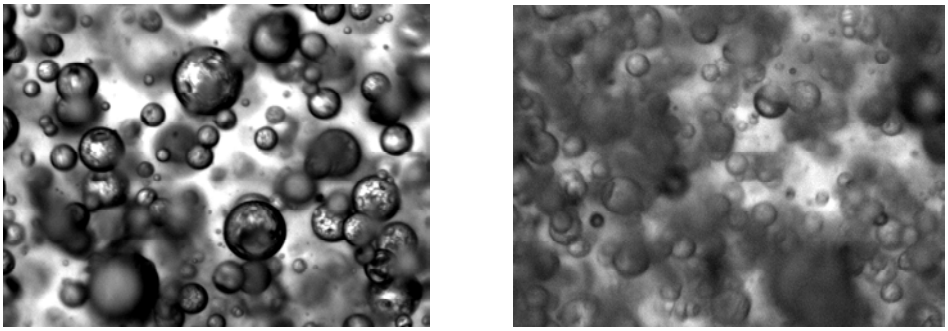

Figure 1: Examples of images, the leftmost is a very good image and the rightmost is a difficult image.

2 Description of the method

In our approach, implemented in Matlab (Gonzalez and Woods 2004), given one of the photographic images of dispersion, automatically identifies the contour of existing drops and classifies them according to their diameter.

This work for the detection of the drops in an image was done in two distinct steps. In the first step, we detect the edges of the drops in the original image, manipulating the gradient and the descending thickness and creating an output image with those contours. In the second phase, we detect the drops in this contour image, using the Hough Transform (Russ 2006). This transform is widely used in image processing to detect lines and also to detect circles.

2.1 Edges detection

In Figure 2 we show the phases of the detection process of the drops. Thus, starting from the original image (leftmost), we detect the edges (centre) and, in the next step, we detect the contours of the drops using the Hough transform (rightmost).
In our images, of poor quality, the drops have, in majority, dark edges.

Figure 2: Original image, the edge detection and the detection of the drop using the Hough transform.

To reduce the noise, the image is smoothed using a Gaussian filter. This eliminates some false contours and reduces the detection of false drops.

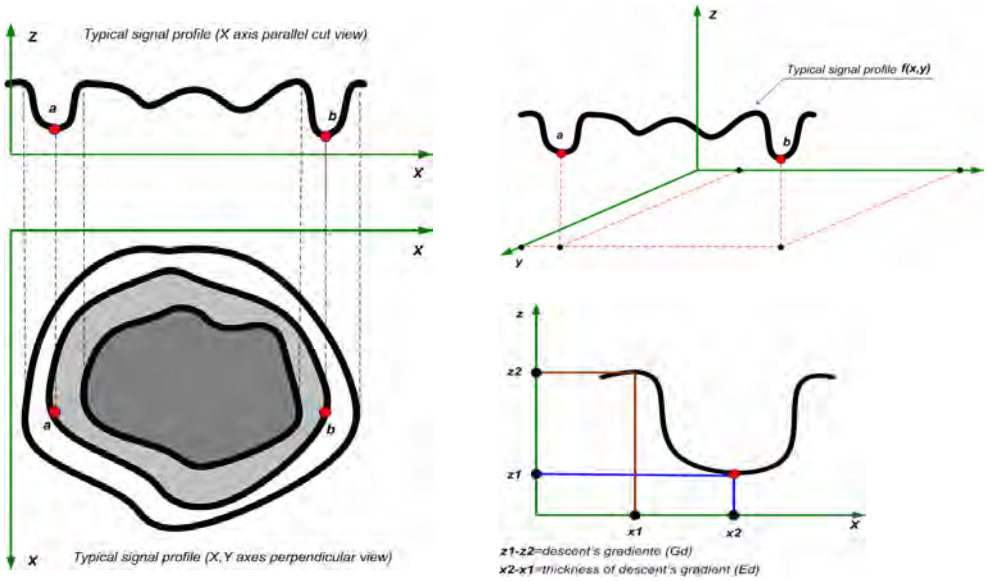

Figure 3: Typical signal profile

Using the typical profile of the signal, edge detection is made by evaluating the relation between the gradient's descent (Gd) and its respective thickness (Ed), shown in Figure 3.

The filtered image (If) is derived, with kernels of convolution, indicated below, originating two matrices, Ix and Iy (see Eq. (1)) corresponding to the partial derivatives dz/dx and dz/dy:

$$Ix = If * \begin{bmatrix} 1 & -1 \end{bmatrix} \quad Iy = If * \begin{bmatrix} 1 \\ -1 \end{bmatrix} \tag{1}$$

From the images Ix and Iy we obtain the average and the standard deviation of the descending gradient (μg, σg) and the average and the standard deviation of the descending thickness (μe, σe). The edge detection threshold is defined by the combination of Gd and Ed, where Gd takes negative values and Ed positive. In processing of each descent (negative derivative) from its origin to inflexion point, if Ed>μe-σe/2 and Gd<μg+σg/2, then the pixel of this point is considered an edge pixel. From the matrix Ix we obtain the partial contour matrix Ia, and from Iy the matrix Ib. The sum of Ia and Ib yields the contour image Ic, shown in Figure 4.

Preliminary experiments with other known methods for contour detection such as Sobel, Canny and Marr Hildreth showed that these degrade the results of the Hough Transform in the detection of the drops. They introduce additional information that causes the detection of false drops.

2.2 Detection of drops in the contour image

In the second step of the work, we applied the Hough transform to the contour image Ic (Figure 4 a) to detect the contour of the drops for different radius.

We consider, as we can see in (Figure 4 b), that the contour of each drop can be represented as one object with irregular form, centred in a point and with a radius that varies from $r1$ to $r2$.

The Hough transform is widely used to detect lines and also to detect circles. To find circles using a Hough transform, each edge element votes for all the points x, y which are centres of the circles with radius r that it could lie on. This transform allows determining the centre of the drop through the identification of the most voted zone. It has the inconvenience of, for each useful vote, generating $2 \times \pi \times r - 1$ noise votes. In an image with many drops, this could

cause the detection of inexistent drops.

a) b)

Figure 4: Drop contour – a) the resulting contour image; b) representation of the drop contour as an irregular object.

In the second step of the process we applied the Hough transform to the contour image Ic taking into account the relative deformation (*k*) of the drops. For a maximum deformation of radius *r*2 the minimum deformation will be *r*1=*r*2×(1-*k*). Votes will be generated from the successive application of the Hough Transform to the range *r*1:*r*2.

This procedure is repeated for all the radii considered as maximum deformation, in order to process all the contours of all dimensions of the drops. The voting window (centre of Figure 5Figure 6) has a dimension of 3x3 pixels for radii above 15 and dimension of 1x1 otherwise. To reduce the number of noise points we considered half of the voting amplitude (two quadrants). For that we analyse the signal of the partial derivatives according to the partial contour matrix, Ia or Ib, related to the edge pixel.

Figure 6 illustrates the detection quadrant voting procedure for an edge pixel related to matrix Ia. If the drop was a regular solid, it would be possible to determine the correct quadrant, by analysing the gradient's angle variation, *β*. In our case, it is only possible to determine a pair of possible voting quadrants (A, C or B, D), by analysing the partial derivative's signal. The similar process is used for the edge pixels related to matrix Ib.

The detection process starts with the set of drops with radii between 17 and 48 pixels because these are the most frequent. This detection is accomplished with the erosion of the contour image to avoid the false drops with a higher radius. Then we treat the drops with at least 48 pixels of radius. Finally we process the drops with radius between 8 and 16 pixels.

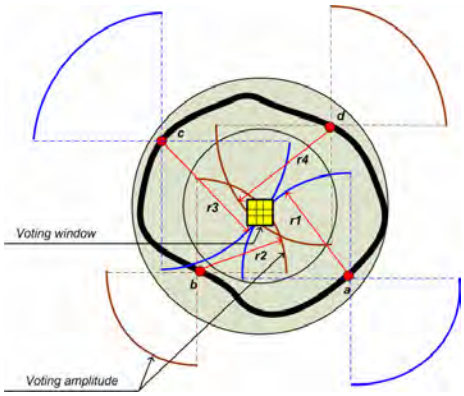

Figure 5: Voting window and voting amplitude.

Processing the drops with higher radius first, reduces the probability of detecting false drops with a lower radius, caused by agglomerates of pixels in the contour of the drops. However, the detection is not efficient for radii below 8 pixels.

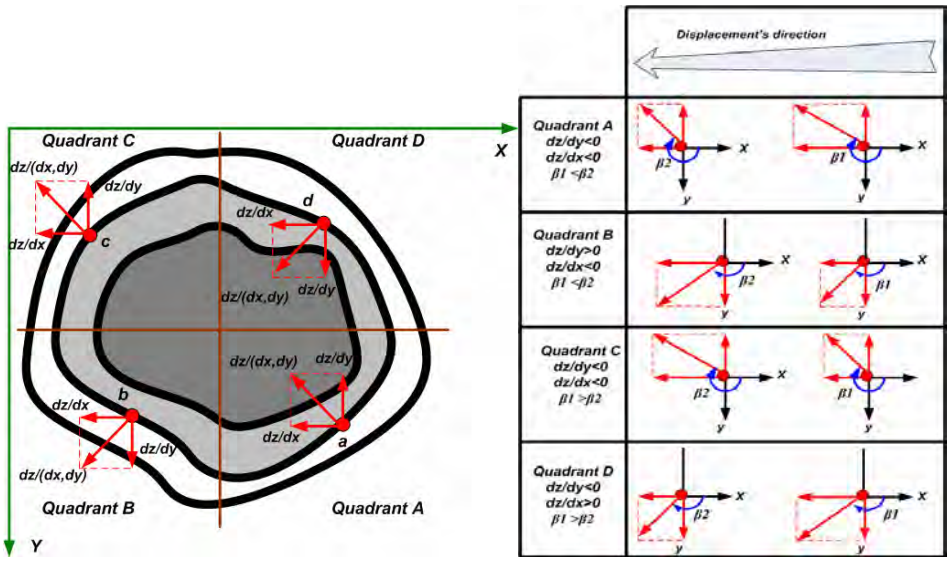

Figure 6: Detection of the quadrant voting across the X axis

In Figure 7 we can see the results obtained for a radius between 5 and 46 pixels.

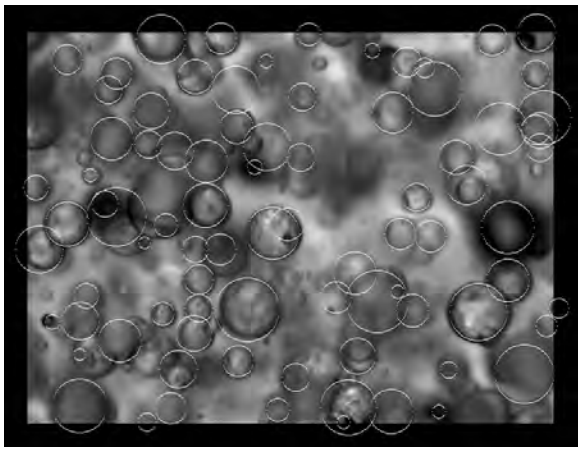

Figure 7: the drops detected by our program. Each detected drop is marked with a white circle on top of the original image.

3 Results

To evaluate more objectively our approach we have chosen two images with different levels of photographic quality, and compared the sets of drops obtained automatically with the drops manually identified by us. In Table 1 we show the results obtained with two of the images in terms of recall and precision values. We have calculated those values as defined in Eq. (2) where *TP* is the true positives (number of drops correctly identified by the program), *FN* the false negatives (actual drops not identified by the program) and *FP* the false positives (drops incorrectly identified by the program). In other words, recall measures the proportion of existing drops that the program was able to identify correctly, whereas precision is the proportion of drops identified by the program that are truly correct.

$$recall = \frac{TP}{TP + FN} \qquad precision = \frac{TP}{TP + FP} \tag{2}$$

In the case of the first image, we have obtained the following results. For a radius less then 7 pixels the program cannot find any drop. For the radius 10, not in the table because recall=0

and precision not defined, we have *TP*=0, *FP*=0 and FN=3. For the radius 12, also not in the table, because recall=0 and precision not defined, we have a *TP*=0, *FP*=0 and *FN*=1. For the other values of the radius not represented in the table, we have *TP*=0, *FP*=0 and *FN*=0. As final results, taking into account all the values of radius, we have for this image a recall of 0.71 and a precision of 0.89.

Table 1: Precision and Recall for different radii on two images

First image						Second image					
Radius (pixels)	Recall	Precision	Radius (pixels)	Recall	Precision	Radius (pixels)	Recall	Precision	Radius (pixels)	Recall	Precision
7	0.25	1.00	17-19	1.00	0.90	7	0.44	0.80	16	0.57	1.00
8	0.50	1.00	20	0.75	1.00	8	0.50	1.00	17	0.77	1.00
9	0.57	1.00	21	0.60	0.60	9	0.40	1.00	18	0.57	1.00
11	1.00	0.67	22	0.60	1.00	11	0.25	1.00	19	0.50	1.00
13	0.67	1.00	23	0.67	1.00	12	0.25	1.00	20	0.50	0.60
14	0.80	1.00	24	0.33	1.00	13	0.25	0.50	22	0.25	0.33
15	0.67	1.00	25-26	1.00	0.75	14	0.57	0.57	23	0.75	1.00
16	0.75	0.75	28-44	1.00	1.00	15	0.57	1.00	24-44	1.00	1.00

For the second image, which has a lower photographic quality, we have worse results, having a total 0.55 for recall and 0.87 for precision. Nevertheless we have, for many values of radius in the image, maximum recall and precision. For several values of radius from 7 to 23 and for radius equal to 35, 40 and 45, recall and precision are not shown in the table, for the same reasons as in the previous image. We believe the cause for these worse results with respect to the previous image is the lower quality of this second image.

4 Conclusions

In this paper we have presented a method for the automatic identification of drops in images taken from agitated liquid-liquid dispersion. The results obtained with two images lead to the conclusion that our program is able to detect a good percentage of the drops. In the case of a better quality image, the program recognized 71% of the drops. For the other image, with lower quality, only 55% were detected. We have also observed that the approach is less efficient for smaller values of the radius, since very small drops can be easily mistaken by noise.

Topic: Integration of life sciences & engineering

Abstract

Monitoring activated sludge processes by microscopic observations and image analysis methodologies is a well established technique with the utmost importance for microbial community characterization. Furthermore, image processing and analysis is currently considered a powerful tool to identify and quantify biomass morphological and physiological changes. In the present work, image processing and analysis methodologies were used to determine aggregates and protruding filaments contents and morphology using both bright field and phase contrast microscopy. The obtained results showed that the simpler and less expensive bright field microscopy also provided the best overall results.

1 Introduction

An activated sludge system includes a complex ecosystem composed of different types of microorganisms such as protozoa, metazoan and filamentous, zoogleal and other bacteria. A good balance between the different types of microorganisms is essential to guarantee good settling properties and a clear supernatant which can be performed by visual inspection under an optical microscope coupled to automated image analysis methodologies. As a matter of fact, in recent years, activated sludge processes have been already monitored through microscopic observations for aggregates contents and morphology and protruding filamentous bacteria contents determination (da Motta *et al*., 2001, Amaral and Ferreira, 2005, Jenné *et al*., 2007).

Automated image analysis is considered to be a feasible method to characterize quantitatively both aggregated and filamentous bacteria, with two image acquisition methodologies standing out: phase-contrast microscopy as proposed in the works of Cenens *et al*., 2002 and Jenné *et al*., 2007 among others; and bright field microscopy as in the works of da Motta et al., 2001, and Amaral and Ferreira, 2005. In comparison, bright field microscopy is the cheapest and simplest activated sludge examination methodology, whereas the phase-contrast microscopy requires more expensive equipment and a skilled operator. Furthermore, the inner nature of the phase contrast microscopy causes the aggregates borders to become ill-defined, as the objects hallo hinders the assessment of their boundaries. However, this methodology presents the advantage of a more precise determination with respect to the protruding filamentous bacteria contents. As a matter of fact, the high transparency of the filamentous bacteria poses a contrast problem in bright field microscopy acquisition, opposite to the clear filaments/background distinction in phase contrast microscopy. Therefore, it comes as no surprise that studies have already been

performed using bright field acquisition methodologies to survey aggregated biomass and phase contrast acquisition for filamentous bacteria assessment (Amaral, 2003).

In order to determine the best image analysis acquisition methodology of activated sludge samples, the present work aims to determine both protruding filamentous bacteria and aggregated bacteria contents using, on one hand, bright field microscopy and, on the other, phase contrast microscopy.

2 Material and Methods

Experimental study

The biomass used in this study was collected from the aeration basins of seven wastewater treatment plants, treating domestic effluents, located in the North of Portugal. Samples were taken to perform microscopic observations, in order to estimate the contents of the microbial aggregates and protruding filamentous bacteria by image acquisition and analysis. For each sample, the biomass content (TSS) was determined by dry weight (APHA *et al*., 1989).

Image Acquisition

A volume of 25 µL was placed on a slide and covered with a 20x20 mm cover slip for visualization and image acquisition in bright field and phase contrast microscopy. Roughly 200 images were acquired per sample to obtain significant data for both acquisition methodologies.

Bright field microscopy: Images were acquired in a Leitz Laborlux S optic microscope (Leitz, Wetzlar), with 100x magnification, coupled to a Zeiss AxioCam (Zeiss, Oberkochen). Image acquisition was performed in 1300 x 1030 pixels and 8-bit format through the commercial software Axio Vision 3.1 (Zeiss, Oberkochen).

Phase contrast microscopy: Images were acquired in a Diaphot 300 microscope (Nikon Corporation, Tokyo) with 100x magnification, coupled to a Sony CCD AVC–D5CE (Sony, Tokyo) grey scale video camera. The images were acquired in 768×576 pixels and 8-bit format by a Data Translation DT 3155 (Data Translation, Marlboro) frame grabber using the commercial software package Image Pro Plus (Media Cybernetics, Silver Spring).

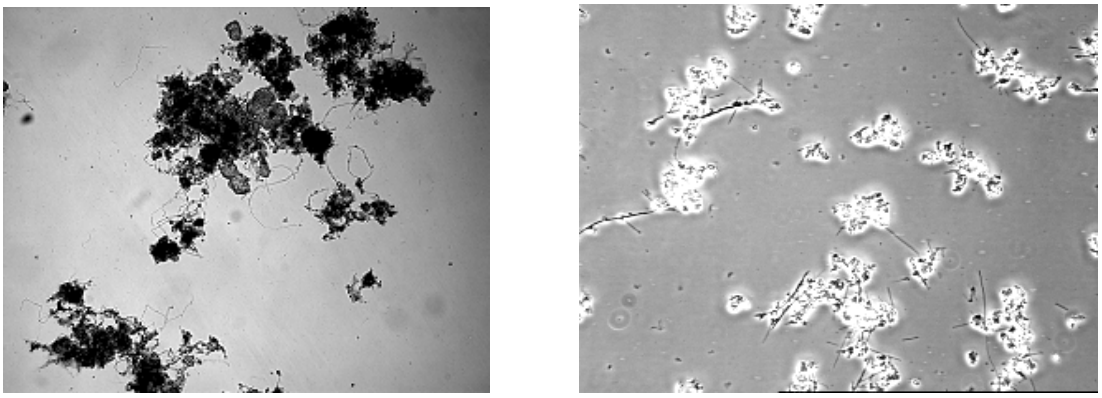

Figure 1. Bright field and phase contrast images.

Calibration from pixels to the metric unit dimensions was performed by means of a micrometer slide.

Image Processing and Analysis Methodology

The aggregates and filaments contents and morphological descriptors were determined by means of image processing and analysis methodologies developed in Matlab 7.3 (The Mathworks, Inc., Natick) language adapted from a previous program developed by Amaral and Ferreira (2005).

The image processing and analysis methodology is divided into two stages. Primarily, the image processing program determines and saves both the aggregated and protruding filamentous biomass binary images. Secondly the image analysis program proceeds to the aggregates and filaments contents and morphological parameters determination.

Image Analysis Parameters

Supported on the previous study of Amaral and Ferreira (2005) 4 parameters were determined, either directly from the image analysis program, either in association with the sludge physical properties, for a total of 131 different samples. Total aggregates area (TA), total filaments length (TL), total filaments length per volume (TL/Vol), total aggregated area per volume (TA/Vol), and total filaments length per total aggregates area (TL/TA) were determined alongside the total filaments length per total suspended solids (TL/TSS) characterizing the aggregates and filaments dynamics. Those parameters were used to establish the best acquisition methodology for both aggregated and protruding filamentous bacteria. A more detailed description of each parameter can be found in Amaral and Ferreira (2005).

3 Results and Discussion

The results herein depicted in Figure 2 revealed a similar trend for both acquisition methodologies with respect to the four studied parameters. However, it is also notorious some differences regarding the absolute value of the TA/Vol (Figure 2a) and TL/TA (Figure 2c) throughout the whole of the data points and in TL/Vol (Figure 2b) and TL/TSS (Figure 2d) in some samples.

Analyzing the aggregated biomass contents, in terms of TA/Vol (Figure 2a), throughout the data points the values obtained for the phase contrast methodology were higher than for the bright field methodology. As a matter of fact, the full data set revealed a 42% increase on the TA/Vol values for the phase contrast acquisition. Given the poorer representation of the objects boundaries in phase contrast microscopy, it seems safe to conclude that this methodology overestimated the aggregated biomass contents considerably.

With respect to the protruding filamentous bacteria contents, in terms of TL/Vol (Figure 2b), for a significant part of the analyzed data, phase contrast and bright field methodology provided similar results. However, for most of the data points there seems to take place a slight overestimation for the bright field microscopy. This fact resulted in an 18% increase on the TA/Vol values for the bright field acquisition. Given the better filaments/background contrast obtained by the phase contrast microscopy, these results were not expected. However, these results may be explained by the fact that the activated sludge samples analyzed in this work presented low protruding filamentous bacteria contents, and that the aggregates area is overestimated in phase contrast. That being the case, the filaments true length would be shortened by the halo of the aggregates in phase contrast, which is a pressing matter in the studied activated sludge, which presented low (and short) protruding filamentous bacteria.

The difference between bright field and phase contrast acquisition is also quite clear when observing the TL/TA (Figure 2c) which comprises only image analysis information (expressing filaments per aggregates area). Bright field microscopy seems to provide higher results than phase contrast which is due to the highest recognition of filaments and lowest aggregates detection. Therefore, it comes as no surprise that, the analysis of the full data set revealed TL/TA values for the phase contrast acquisition that were half of the bright field values.

According to Schuler and Jassby (2007), expressing filaments contents per mass (TL/TSS) is probably the most useful way for comparing filaments contents data from different studies and/or from samples with different biomass concentrations. Given the fact that such concentrations can vary greatly from one system to the other this approach normalizes filaments contents to biomass. Regarding this parameter behavior (Figure 2d) with biomass

normalization, a similar trend between the bright field and phase contrast methodologies arises when compared to the TL/Vol analysis. The main difference relies on the fact that the phase contrast TL/TSS ratio underestimation slightly increased to 22% instead of 18%.

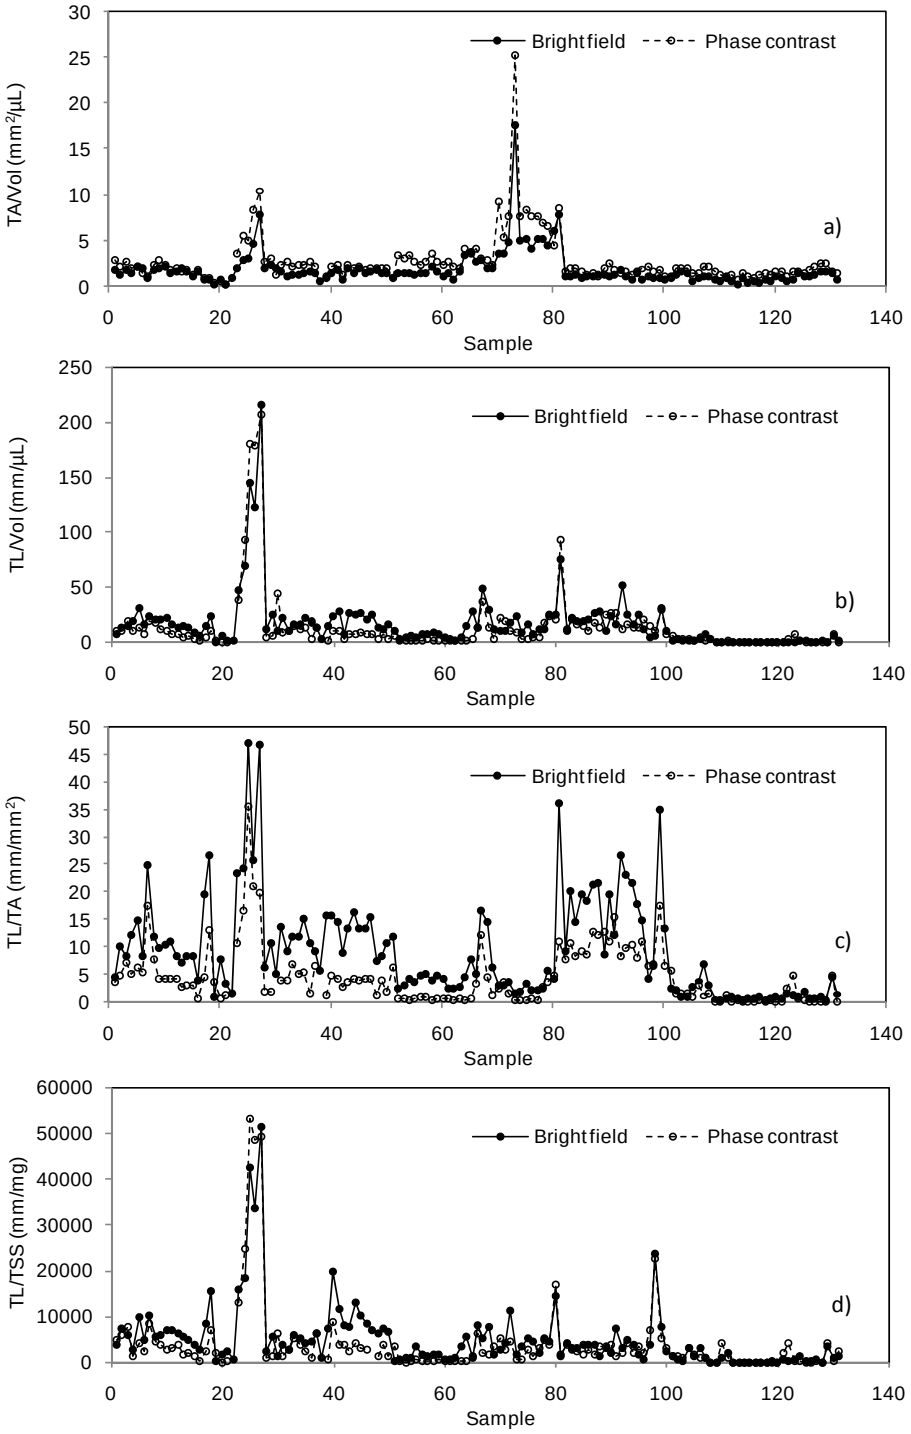

Figure 2. Bright field and phase contrast results for TL/Vol (a), TA/Vol (b), TL/TA (c) and TL/TSS (d) considering 131 samples.

Regarding the behaviors presented in Figure 2, it seems clear the existence of a correlation between the results for bright field and phase contrast microscopic acquisition. Bearing this in mind, were seek the relationships between the bright field and phase contrast results, in order to establish the best acquisition methodology for both aggregated and protruding

filamentous bacteria. Figure 3 represents the obtained relationships between bright field and phase contrast methodologies.

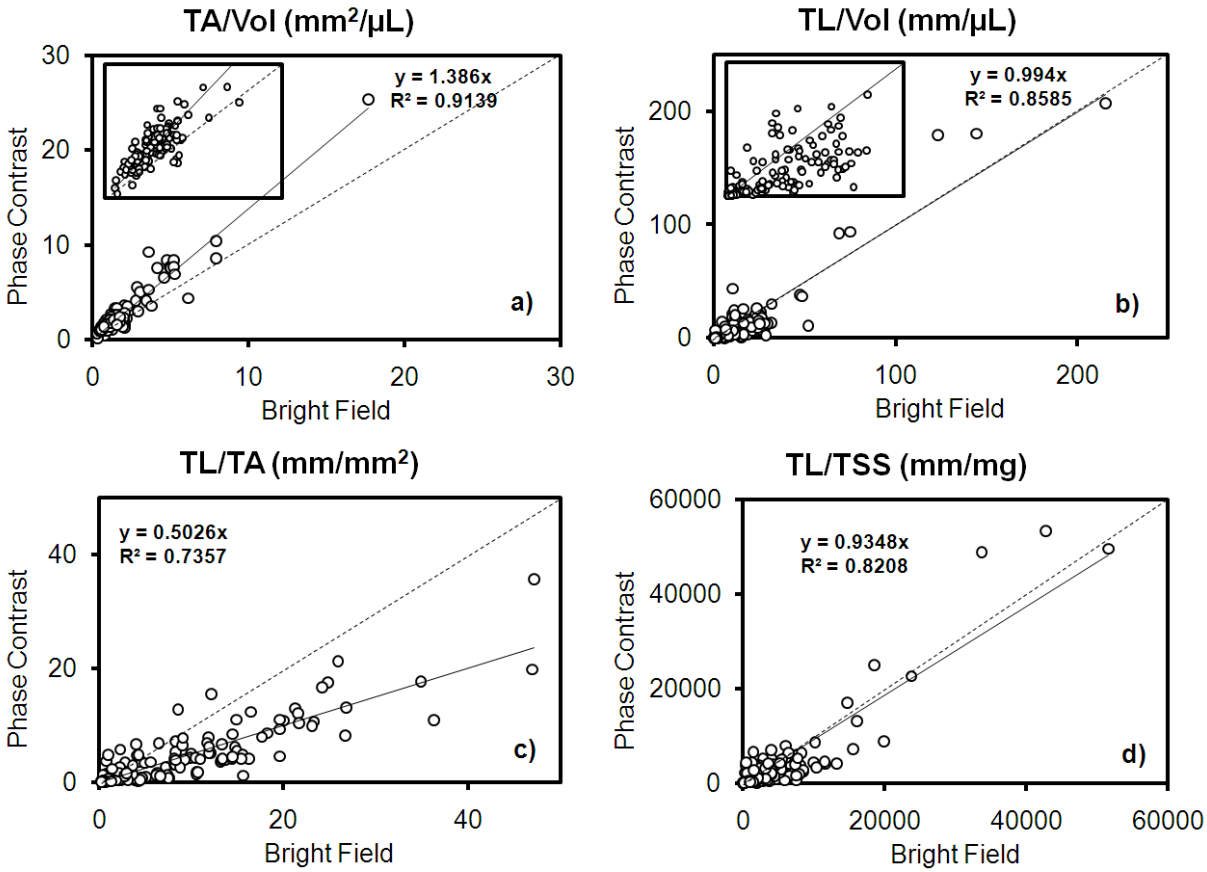

Figure 3. Bright field and phase contrast regressions for TL/Vol (a), TA/Vol (b), TL/TA (c) and TL/TSS (d).

The results herein reported in Figure 3a, revealed a satisfactory correlation coefficient (0.956) for the TA/Vol between bright field and phase contrast assessment. Again, it was possible to infer that the phase contrast methodology overestimated the aggregates detection with respect to the bright field acquisition method. Furthermore, the obtained trend line for the TA/Vol estimation points towards a global overestimation around 39% which is not far apart from the 42% obtained in the previous point to point analysis.

With respect to the protruding filamentous bacteria recognition (Figure 3b), the obtained correlation (0.927) was not as satisfactory as for the TA/Vol and a higher dispersion between bright field and phase contrast assessment was noticed. Furthermore, the trend line pointed to a global correspondence between the two methodologies against the phase contrast underestimation of 18% in the point to point analysis. The reason between such discrepancies may be attributed to the importance of the larger TL/Vol points with respect to the correlation determination. As a matter of fact, the lower values on larger filaments contents of the bright field methodologies, compensates, at some extent, the larger values obtained for smaller contents. It should be noted that, in larger filaments contents, the advantage of the phase contrast methodology on filamentous bacteria recognition is less hindered by the ill defined aggregates borders, leading to a more precise (and higher) filaments determination. All things considered, the correspondence found between the two methodologies allows inferring that the bright field acquisition does not lead to overall significant errors with respect to the protruding filamentous bacteria determination. However care should be taken in analyzing the results of bright field acquisition from activated sludge with high filamentous contents.

Observing Figure 3c, a considerable dispersion between bright field and phase contrast assessments was detected and a poor 0.858 correlation coefficient for the TL/TA ratio was achieved. This result might be due to the cumulative sum of impreciseness both in terms of TL and TA, resulting also in a strong underestimation of this parameter in phase contrast acquisition. This conclusion is further emphasized by the 0.50 slope obtained. This results in a global 50% underestimation of the TL/TA ratio by the phase contrast methodology which is in accordance with the 50% reduction in the previous point to point analysis.

Regarding the TL/TSS ratio results (Figure 3d), a non completely satisfactory correlation coefficient of 0.906 was obtained meaning a global underestimation for the phase contrast of 7% (0.93 slope). Again, a discrepancy was found between the 7% underestimation pointed by the trend between the two methodologies against the phase contrast underestimation of 22% in the point to point analysis. The reason for this behavior is directly related to the protruding filamentous bacteria estimation differences found in the two methodologies, and the same caution must be applied in the TL/TSS ratio as in the TL/Vol assessments.

4 Conclusions

This study clearly demonstrated that, with respect to the protruding filamentous bacteria, the bright field acquisition results mimic, at a certain extent, the phase contrast results. However, the inverse relationship does not hold true for the aggregated biomass contents assessment for the phase contrast acquisition. In fact, it was found that this methodology overestimates by approximately 40% the results obtained by the bright field approach. Thus, considering the advantages and disadvantages of each acquisition methodology and the obtained results, the bright field microscopy proved to be not only more simple and inexpensive but also provided the best overall results.

Keywords: metagenome, heavy-metal resistance, 16S rDNA
Topic: Systematic methods and tools for managing the complexity

Abstract

The composition of microbial populations of tailings waste at the abandoned São Domingo's copper mine was investigated, and the ability of pure and mixed cultures of indigenous microorganisms to reduce sulphates was examined. Average grades of the exploited material range from 1.25% Cu (10% Cu maximum), 2-3% Zn and Pb (14% Zn and Pb, maximum). Massive pyrite grades average in the range from 45- 48% in sulphur, and in addition to pyrite there are subordinate amounts of chalcopyrite, sphalerite, galena and other rarer sulphides (Webb, 1958).
These approaches revealed new genes and gene products that may have a major role in biomining processes.

1 Introduction

Despite the dominance of microorganisms in the biosphere, relatively little is known about the majority of environmental microorganisms, largely because of their resistance to culture under standard laboratory conditions. As such, alternative approaches are required to assess the large amount of information in the environmental metagenome.
An often-cited estimate is that as much as 99% or more of microbial life remains unculturable, and therefore cannot be studied and understood in a way that microbial ecologists have become accustomed to over the past century. Although the portrait of the microbial world was revolutionized by analysis of 16S rRNA genes, such studies yielded only a phylogenetic description of community membership, providing little insight into the genetics, physiology, and biochemistry of the members. Metagenomics provides a second tier of technical innovation that facilitates study of the physiology and ecology of environmental microorganisms. A variety of chemolithotrophic and heterotrophic microorganisms are responsible for the solubilization of metals from sulfide minerals in acidic environments.

2 Materials and Methods

Samples of soil and water from an abandoned cupric pyrite mine (Mina de S. Domingo's, Southeast Alentejo, Portugal) were used in batch assays to study the dynamics of AMD mesophilic population in presence of iron and plumb. The inoculum (34) (200 ml) was

grown 15 days in (g l^{-1}): 1.2 Na_2SO_4; 0.16 $CuSO_4.5H_2O$; 1.245 $FeSO_4.7H_2O$; 0.33 $ZnSO_4.7H_2O$; 0.3 $Na_3C_6H_5O_7$, pH 6.0, final volume 600ml (34). This culture (200 ml) was then subjected to a double concentration of the metals (same volume) used previously, during 1.5 months (29) and sub-cultivation was dome with supplementation of culture medium with 2% (w/v) Pb (35) and 4% (w/v) Pb (36).
Separation of whole DNA from samples of each batch assay including original inoculum (34, 29, 35, 36) was performed using UltraClean soil DNA isolation Kit (MO BIO).
After isolation of gDNA, PCR was performed using 16S rDNA primers for bacteria and archaea, primers 1510R and 1492R respectively, (Hugenholtz and Goebel, 2001). The amplicons were inserted in pJET plasmid (CloneJET PCR cloning kit, Fermentas) and a metagenomic library was constructed with recombinant DH5a cells with clones with partial 16S rDNA genes that were sequenced by an ABI PRISM 310 sequencer (Applied Biosystems). In order to assess the composition of microbial population in what concers the most representative genera, it was study the presence of *Acidiphilium* sp., *Leptospirillum* sp., *Sulfobacillus* sp., (De Wulf-Durand et al., 1997) and *Thiobacillus caldus*, *T. ferrooxidans* and *T. thiooxidans* belonging to *Acidithiobacillus* gen. nov. sp. genus. (Kelly and Wood, 2000). The 16S rDNA PCR products (from universal primers) were used as templates in PCR with 12 specific 16S rDNA primers for typical AMD communities.

3 Results and Discussion

Primers based on 16S rRNA sequences were designed to be specific for bacterial groups and clones described in bioleaching environments. The 16S rRNA sequence data was obtained from the EMBL and GenBank databases.
The 16S rRNA genes specific for each strain were cloned from acidophilic bacteria obtained from enrichment cultures (Figure 1).

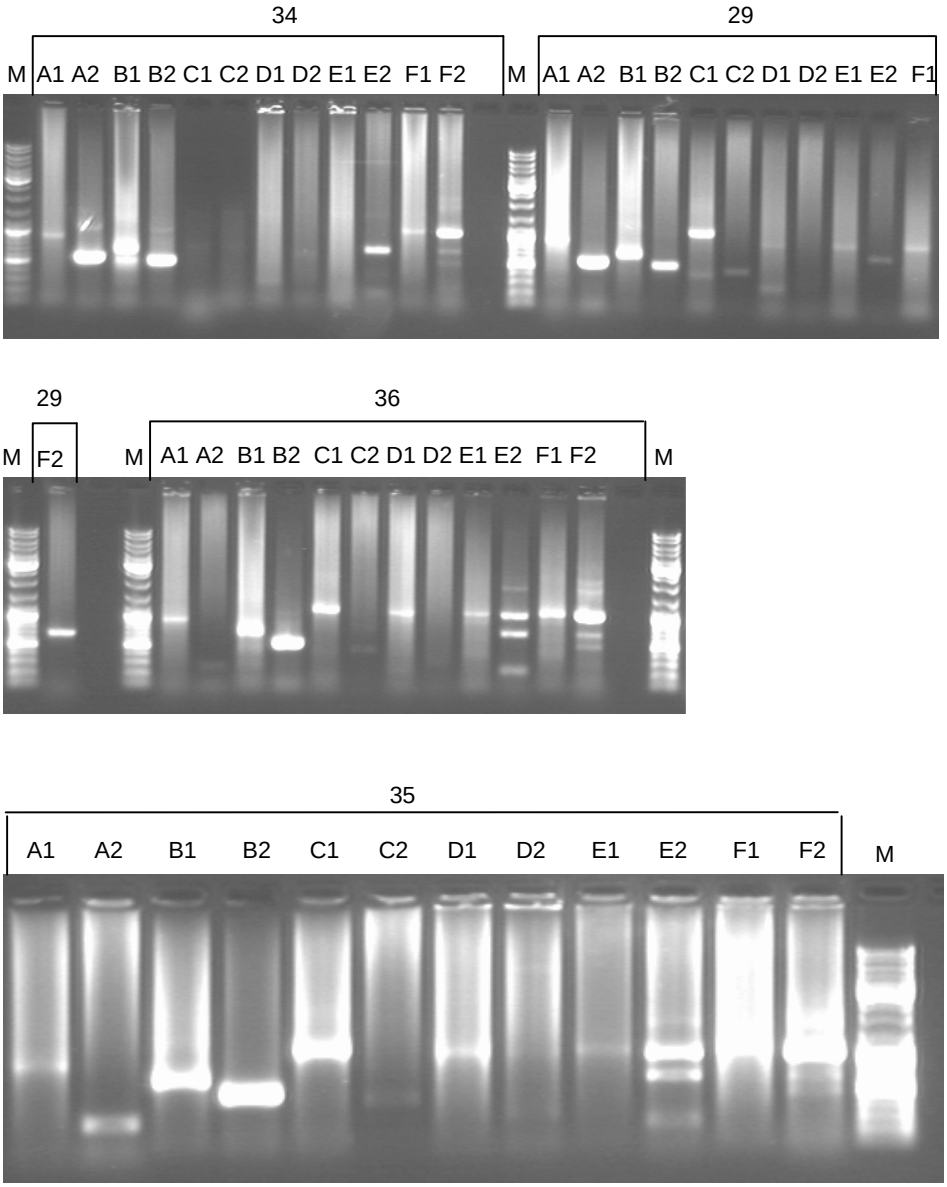

Fig 1. PCR amplifications with AMD specific primers, which templates were the 16S rDNA PCR products amplified with 1510R and 7F universal primers.
A12 – *Acidiphilium* sp., B12 – *Leptospirillum* sp. C12 – *Sulfobacillus* sp., D12 – *Thiobacillus caldus*, E12 – *Thiobacillus thiooxidans,* F12 – *Thiobacillus ferrooxidans.*

The sequence data was compared with 16S rRNA sequences deposited in public databases by using the BLAST search program. The 16S rRNA gene sequences of various bacteria (including those closely related to the unknown sequences, as indicated by the BLAST search) obtained from the GenBank database (Figure 2).

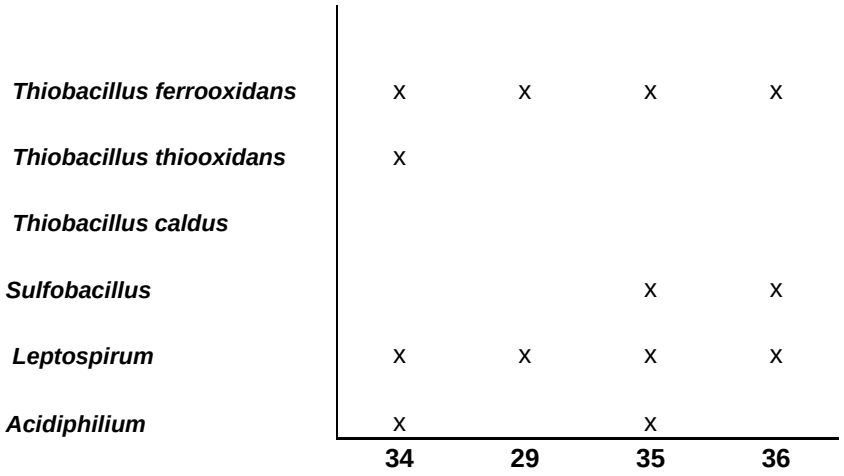

Fig 2. Dynamics of bioleaching population. 34, 29 (presence of copper, iron and zinc) 35 (2% Pb), 36 (4% Pb).

A combination of cultivation-based and molecular-based approaches was used to reveal the culturable and molecular diversity of the microbes inhabiting an open-dumped Pb/Zn mine tailings Analysis the sequences obtained from the metagenomic library constructed with each pool of DNA revealed that microbial population suffers adaptive events that can be explained by the effect of selective pressure caused by metal concentration of culture media, in the dynamics of microbial population. The introduction of Pb in culture media, revealed the presence of *Sulfobacillus* sp., that is a thermophilic iron oxidizing bacterium, usually present in the sphalerite (ZnS) concentrate associated to chalcopyrite that revealed to be important in Pb bioleaching.

Equilibrium and kinetics modelling of separation of Cr(III) from industrial effluents by a chelating resin

Licínio M. Gando-Ferreira*, Margarida M. Quina, Sofia A. Cavaco and Rosa Quinta-Ferreira
GERSE - Group on Environment, Reaction and Separation Engineering, Chemical Engineering Department, University of Coimbra, Pólo II, 3030–790 Coimbra, Portugal

Keywords: Equilibrium; Langmuir; Chromium; Breakthrough curves; Multicomponent adsorption
Topic: Advancing the chemical engineering fundamentals.

Abstract

In this study, a chelating resin containing iminodiacetic acid group (Diaion CR 11) was investigated to separate chromium(III) and copper from synthetic effluents. To determine single-component equilibrium isotherms for the two species, batch experiments were performed at 25 ^{o}C. On basis of these results, it was found that the resin exhibited better selectivity for Cu over Cr (III). The Langmuir model enabled a good description of the ion-exchange equilibrium data. To study the dynamic behaviour of the process, column tests were performed for monocomponent - Cr(III)/Diaion CR11 and multicomponent - Cr(III)/Cu^{+2}/Diaion CR 11 adsorption systems. A mathematical model considering dispersed plug flow for the liquid phase, intraparticle mass transfer by pore diffusion and external mass-transfer resistance at the pore/wall interface enabled a reasonable description of the experimental breakthrough curves.

1. Introduction

The environmental contamination with heavy metals may create acute or chronic toxicity problems, which should be avoided when ever is possible. Indeed, although heavy metals could be found naturally in soils, sediments, water and even in living organisms, anthropogenic releases can increase its concentration to higher levels. The electroplating processes is an example of an industry that may create serious problems, since their wastewaters may contain large number of heavy metals, including chromium, copper, nickel, zinc, manganese and lead. The specific contaminants addressed in our work were chromium and copper.

The chromium was selected mainly due to its high concentration in electroplating effluents, commercial value and also based on health concerns (hexavalent chromium is potentially carcinogenic when inhaled). Copper is in general a heavy metal of serious concern because of its toxicity to aquatic life.

The ion exchange process showed to be a promising alternative technique to the traditional methods of precipitation coupled with filtration, for removal and recovery Chromium. The chelating resins are commonly employed as ion-exchange materials, once their ligands can selectively bind to certain metallic ions. Recent studies (Cavaco *et al*. 2007; Gode *et al*. 2003; Kabay *et al.* 1998, 2003) have shown that these resins could be used for the selective removal and recovery of chromium (III). In this work the performance of a chelating exchange resin (Diaion CR11) was evaluated for a system with two species: Cr(III) and Cu. In order to assess the sorption capacity of the resin some equilibrium experiments were carried out, as well as transient column tests for understanding the kinetic behaviour of the process. The experimental results were very motivating, and are now complemented with the modelling approach, since it allow the enhancement and the understanding of the global process.

2 Theory

2.1 Adsorption equilibrium model

In order to quantitatively describe the adsorption experimental data obtained by the batch technique, the Langmuir equation was used:

$$q_i = \frac{q_{\max i}\, k_{Li}\, C_i}{1 + k_{Li}\, C_i} \tag{1}$$

where q_i correspond to the adsorbed mass of component i (mg/g wet resin) and C_i is the equilibrium concentration of component i (Cr and Cu^{2+}) in the liquid phase (mg/L). K_{Li} and q_{maxi} are the Langmuir model parameters.

2.2 Dynamic Model for Fixed Bed Adsorption and Parameter Estimation

A model was developed to describe the dynamic behaviour of the system during the saturation step, namely regarding the species concentrations in the solution at the outlet of the column as a function of time (breakthrough curve). The model includes pore diffusion, mass transfer resistance in the film and axial dispersion. Dimensionless model equations are:

Mass balance for the fluid phase

$$\frac{\partial \mathrm{X_i}\,(z^*,\theta)}{\partial \theta} = \frac{1}{\mathrm{Pe}} \frac{\partial^2 \mathrm{X_i}\,(z^*,\theta)}{\partial z^{*2}} - \frac{\partial \mathrm{X_i}\,(z^*,\theta)}{\partial z^*} - \mathrm{N_{fi}}\,(\,\mathrm{X_i}\,(z^*,\theta) - \mathrm{Xp_i}\,(1,z^*,\theta)\,) \tag{2}$$

where i = 1(Cr(III)), 2 (Cu^{2+}).

Mass balance inside particles

$$\frac{\rho_h}{C_{E_i}} \frac{\partial q_i\,(u^*,z^*,\theta)}{\partial \theta} + \varepsilon_p \frac{\partial Xp_i\,(u^*,z^*,\theta)}{\partial \theta} = N_{Di}\,(\frac{\partial^2 X_{p_i}\,(u^*,z^*,\theta)}{\partial u^{*2}} + \frac{2}{u^*} \frac{\partial Xp_i\,(u^*,z^*,\theta)}{\partial u^*}) \tag{3}$$

Multicomponent Equilibrium Adsorption pore / wall interface described by the extended Langmuir model

$$q_i = \frac{q_{\max_i}\, k_{Li}\,(C_{Ei}\, X_{Pi} / \eta_i)}{1 + \sum_{j=1}^{2} k_{Lj}\,(C_{Ej}\, Xp_j / \eta_j)} \tag{4}$$

where the q_{maxi}, k_i are given by the individual Langmuir (eq. 1), and the η_i are the interaction terms to quantify the competitive adsorption in multicomponent systems.

Initial conditions

$\theta = 0$ $\quad X_i\,(z^*,0) = Xo_i$ and $Xp_i(u^*,z^*,0) = Xo_i$ (5)

Boundary conditions

$u^*=0$ $\quad \frac{\partial Xp_i\,(u^*,z^*,\theta)}{\partial u^*}\Big|_{u^*=0} = 0$ (6)

$$u^*=1 \quad N_{fi}\,(\,X_i(z^*,\theta) - Xp_i(1,z^*,\theta)\,) = 3\frac{1-\varepsilon}{\varepsilon} N_{Di}\,\frac{\partial Xp_i(u^*,z^*,\theta)}{\partial u^*}\Big|_{u^*=1} \qquad (7)$$

The equations of the model are written in terms of dimensionless variables: $X_i = C_i/C_{Ei}$, $Xp_i = Cp_i/C_{Ei}$ are the dimensionless concentrations of the species i in the bulk liquid phase and in the liquid inside particle pores, respectively; $\theta = t/\tau$ is a reduced time, where τ is the bed space time; z* = z/L is the reduced axial coordinate, where L is the fixed bed length; u* = r/R is the reduced particle radial coordinate, in which R is the adsorbent particle radius.

The dimensionless groups are the Peclet number $Pe = uL/(\varepsilon D_{ax})$ (D_{ax} is the axial dispersion coefficient), the number of mass transfer units by pore diffusion for species i, $N_{Di} = \tau\varepsilon_P D_{Pi}/R^2$ ($D_{pi} = D_{mi}/\tau_p$ is the effective diffusivity for the species i and τ_P is tortuosity factor) and the number of film mass transfer units for species i, $N_{fi} = 3(1-\varepsilon) k_{fi} \tau / (\varepsilon R)$, where k_{fi} is the film mass transfer coefficient for species i. The axial dispersion was calculated from the Butt correlation (Buts, 1980): $(u d_p/D_{ax}) = (0.2 + 0.011 Re^{0.48})$, where $Re = u \rho d_p / \varepsilon \mu$.

Numerical solutions of eqs (2) – (7) were performed by discretizing eq. (3) in the radial direction using orthogonal collocation in NE finite elements with cubic Hermite polynomials as basis functions. This led to a new boundary value problem of N_{comp} (2NE +1) [N_{comp} is the number of components] parabolic PDE's in the independent variables z* and θ that was numerically integrated with the PDECOL package.

3 Experimental Methods

Before the experiments, the resin Diaion CR11 was supplied by Mitsubishi Chemical Corporation and was pretreated by repeated washings with 2M HCl and 2M NaOH solutions to remove solvents and other preparation chemicals. The last step of the conditioning consisted in percolating a solution of HCl through the column in order to convert the resin to H^+ form. The resin matrix is polystirenic and contains the iminodiacetic acid as chelating group. For all the experiments, synthetic effluent samples were prepared by dissolving an appropriate amount of chromium salt $Cr(NO_3)_3$ and copper salt $Cu(NO_3)_2$ in distilled water.

Equilibrium isotherms were determined through batch tests, where 40 mL of a synthetic solution at different initial concentrations of the metal were added into a flask with 1 g of preconditioned resin. The flasks were sealed and kept in a shaker at 25ºC for 24h. The resin was separated by filtration and some aliquots of liquid were analyzed using flame atomic absorption spectrophotometry in order to determine the total concentration of Cr (III) and Cu in solution.

In the column tests, a glass tube with 1.6 cm of internal diameter and 20 cm height, packed with approximately 5 g of resin was used. The experimental conditions for these tests (Run 1 to Run 3) are summarized in Table 1. A peristaltic pump was utilized to percolate 10 mL/min through the column of a synthetic solution containing Cr (III) and Cu^{2+} ions. Several samples were collected at the column outlet and the concentrations of both metals were analysed along the time as described above.

Table 1 – Experimental conditions for fixed bed experiments

	$C_{Cr(III)}$	C_{Cu+2}	Feed pH	Resin Properties	Bed Properties	Flow conditions
Run 1	484 mg/L	-	3.26	ε_p = 0.66	ε = 0.35 L = 4.0 cm	Q = 10 mL/min τ = 0.28 min
Run 2	240 mg/L	160 mg/L	3.30	ρ_h = 1015 g/L	ε = 0.40 L = 5.0 cm	Q = 10 mL/min τ = 0.40 min
Run 3	230 mg/L	70 mg/L	3.11	d_p = 0.536 mm	ε = 0.40 L = 5.0 cm	Q = 10 mL/min τ = 0.40 min

4 Results and discussion

The single-isotherms equilibrium data for Diaion / Cr (III) and Diaion /Cu^{+2} are illustrated in Fig. 1a and Fig. 1b, respectively. These data show that the resin exhibits higher sorption capacity for copper than for the trivalent chromium, this means that Cu^{+2} forms a stronger chelate complex with the functional group (iminodiacetic acid) of the resin.

The metal sorption of both metals leads to a decrease in the equilibrium pH of the solution with respect to initial pH from approximately 5 to 2. This pH variation is a consequence of the hydrogen ions release from the resin, in the H^+ form, since those ions are exchanged with the metallic ions in solution.

The Langmuir model fits very well the equilibrium experimental data, for the conditions tested and for both metals (Cr and Cu). The values found for the parameters are: $K_L = 8.47x10^{-3}$ *L/mg* and $q_{max} = 10.68$ *mg/g*$_{resin}$ for Cr(III); $K_L = 5.97x10^{-2}$ *L/mg* and $q_{max} = 31.75$ *mg/g*$_{resin}$ *for* Cu^{+2}.

Figure 1- Adsorption equilibrium isotherms. Experimental data and model predictions using the Langmuir equation: (a) – Diaion / Cr(III) ; (b) – Diaon / Cu^{+2}.

Experimental and simulated breakthrough curves plotted as metal concentration at column outlet against time are depicted in Figs. 2 – 5.

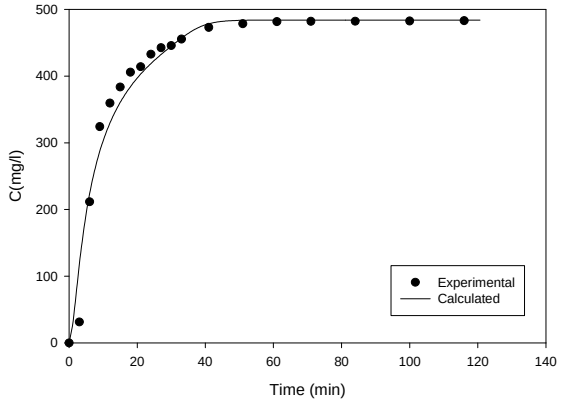

Figure 2 – Breakthrough curve of Cr (III) sorption on Diaion Cr 11 – Run 1.

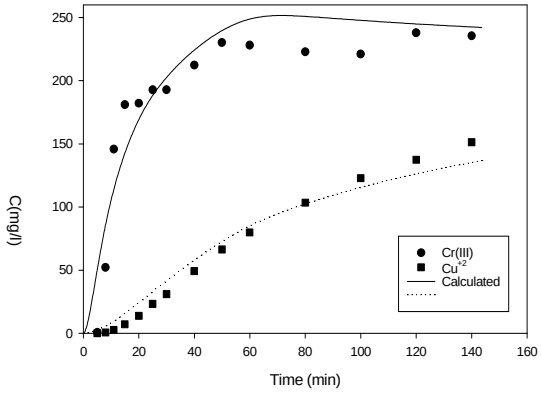

Figure 3 – Breakthrough curves for sorption of the mixture Cr (III) and Cu^{+2} on Diaion Cr 11 – Run 2.

A reasonable agreement is observed between experimental and calculated breakthrough curves, being the model solution achieved with the parameter values indicated in the Table 2. The Peclet values demonstrate a intermediate effect of axial dispersion on the hydrodynamic conditions of the fixed bed, while the $N_{D,i}$ ones enable to conclude that the mass transfer is controlled by the intraparticle resistance. Regarding the N_f parameter, high values were used in the simulations for neglecting external mass transfer resistance.

Table 2 – Parameter values used in the simulations of the saturation step.

	Pe	$N_{D,cr}$	$N_{D,Cu}$
Run 1	33.0	0.04	-
Run 2	52.3	0.06	0.09
Run 3	49.3	0.06	0.09

In the case of multicomponent system, corresponding to the Runs 2 and 3, the equilibrium isotherm for each species took into account the following interaction factors adjusted: η_1 = 1.11 for Cr(III) and η_1 = 0.5 for Cu^{+2}. The breakthrough curves of these runs (Figs 3 and 4), in which the copper concentration in the feed was decreased, show that copper emerges later since this metal is strongly adsorbed by the resin, confirming so the equilibrium studies. It should be noted that the change of the initial copper concentration had effect on the breakthrough time of the saturation curve for this metal. Higher initial concentration leads to faster saturation of the resin and consequently the breakthrough curve emerges at column outlet earlier. The chromium behaviour is little affected by the change of copper concentration feed.

Figure 5 illustrates the effect of the flowrate on the breakthrough curves obtained by simulation. As expected, at low flow rates, a longer contact between the solid and liquid phase is promoted and this leads to the retardation in the saturation curve.

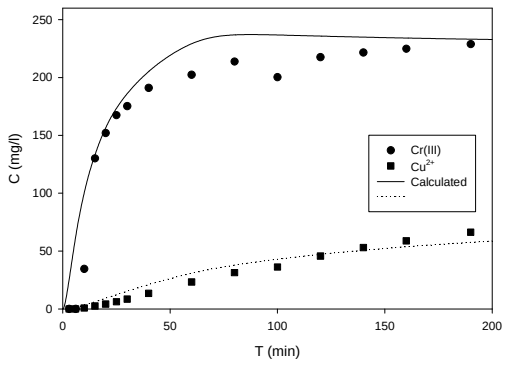

Figure 4 – Breakthrough curves for sorption of the mixture Cr (III) and Cu^{+2} on Diaion Cr 11 – Run 3.

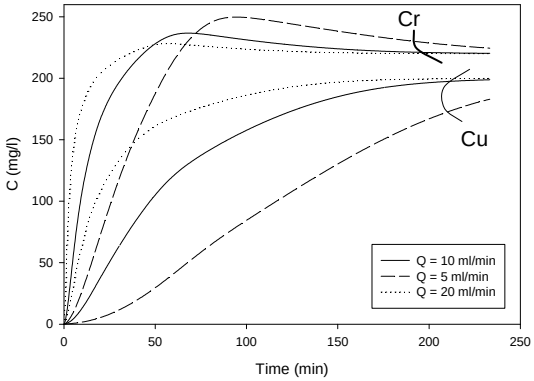

Figure 5 – Effect of the flowrate on the breakthrough curves for sorption of the mixture Cr (III) and Cu^{+2} on Diaion Cr 11.

5 Conclusions

The chelating ion-exchange resin Diaion CR 11, in the hydrogenium form, have been tested for separating chromium (III) and copper from synthetic effluents. The equilibrium isotherms showed that the resin have strong affinity to the copper ions than for chromium. The experimental data were well described by the Langmuir model.
The breakthrough curves resulting from the saturations in fixed bed enabled to study the dynamic behaviour of the process for the monocomponent - Cr(III)/Diaion CR11 and multicomponent - Cr(III)/Cu^{+2}/Diaion CR 11 adsorption systems. A mathematical model considering dispersed plug flow for the liquid phase, intraparticle mass transfer by pore diffusion and external mass-transfer resistance at the pore/wall interface was used to simulate the saturation curves. The model yields results in reasonable agreement with the experimental data and seems to be a suitable approach for the design of industrial systems directed to the treatment of effluents from electroplating processes.

Hydrogen production from methane steam reforming: parametric and gradient based optimization of a membrane reactor

L. C. Silva; V. V. Murata; C. E. Hori; A. J. Assis[1*]

Keywords: Modeling and simulation, sensitivity analysis, reforming reactions, hydrogen, DIRCOL
Topic: Advancing the chemical engineering fundamental.

Abstract

In this work, the effects of five important parameters, as well as, the use of two different intrinsic kinetics available on the model developed were evaluated. The influence of the parameters, inlet reactor pressure (PR0), methane feed flow rate (FCH40), sweep gas flow rate (FI), external reactor temperature (TW) and steam to methane feed flow ratio (M), on methane conversion (X_{CH_4}) and hydrogen recovery (Y_{H_2}) was parametrically evaluated through simulations. In addition, a gradient based method (DIRCOL) was used to perform the optimization of the sum of methane conversion and hydrogen recovery. High methane conversions and H_2 recoveries were reached by parametric optimization, but, disdaining the interactions between the variables. Due to numeric problems in the optimization using DIRCOL, the lower value of methane feed that allowed the optimization was $1 \cdot 10^{-4} mol/s$. It was possible to reach a methane conversion around 96% and a hydrogen recovery of 91%.

1 Introduction

Nowadays, methane steam reforming is the main route for hydrogen production. Methane steam reforming reactions are endothermic and reversible, which implies on the conventional technology, in high operating temperatures to reach satisfactory conversions. Since the maximum conversion that could be achieved is the equilibrium conversion, the membrane technology is an alternative process that can overcome this limitation. Membrane reactors are generally constituted by concentric tubes in which one of them is the membrane. The membrane is usually made of Palladium or an alloy of Palladium-Silver that is only permeable by hydrogen. Therefore, in a membrane reactor, hydrogen is continuously removed from the reaction zone, displacing the chemical equilibrium and enabling operation at moderate temperatures. Satisfactory conversions are dependent on many factors such as the operating parameters. Several studies (Lin et al. 2003, Shu et al. 1994, Falco et al. 2006) have studied the influence of the factors such as operating pressure, methane feed flow rate, operating temperature, sweep gas flow rate, area of permeation, etc., on the methane conversions. In this work a combination of a parametric optimization and a gradient based optimization is made to provide an insight about the choice of some parameters that maximize the hydrogen recovery and the methane conversion for a small scale reactor.

2 Mathematical modeling

In accordance with Froment and Xu (1989) the reactions among methane, water, monoxide of carbon, carbon dioxide and hydrogen that present greater probability to occur during methane steam reforming are:

$$CH_4 + H_2O \leftrightharpoons CO + 3\,H_2 \qquad -\Delta H_{298K} = -206.1\,kJ/mol \tag{1}$$

$$CO + H_2O \leftrightharpoons CO_2 + H_2 \qquad -\Delta H_{298K} = 41.15\,kJ/mol \tag{2}$$

$$CH_4 + 2\,H_2O \leftrightharpoons CO_2 + 4\,H_2 \qquad -\Delta H_{298K} = -165.0\,kJ/mol \tag{3}$$

The reactor modeled is schematically represented in Fig. 1. The inner tube is the Pd-based membrane and the outer one is the shell. The catalyst is packed in the annular region. The inert or sweep gas passes into the inner tube in co-current flow mode.

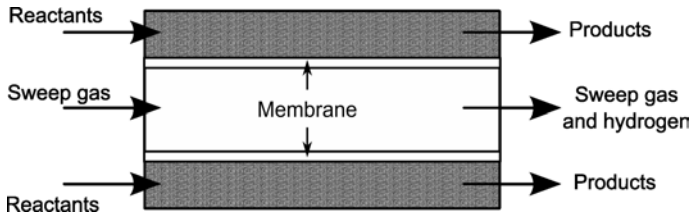

Figure 1: Membrane reactor scheme considered in this work.

The model is summarized by the equations in Table 1. Where, for $\Psi = 0 \Rightarrow i = CH_4, CO, CO_2, H_2O$

Table 1: Model equations

Mass balance in the reaction chamber $\frac{dF_i}{dZ} = W\left(\sum_{j=1}^{3}\nu_{ij}r_j\right) - \Psi J_{H_2} A_m$	Molar flux of hydrogen through the membrane $J_{H_2} = \frac{A_0 e^{\left(\frac{E}{RT_m}\right)}}{\delta}\left((p_{H_2})^{0.5} - (p_{H_2p})^{0.5}\right)$
Energy balance in the reaction chamber $\rho_r C_{v_r} \underline{v_r} \cdot \frac{dT_R}{dZ} = T_R \left.\frac{\partial P}{\partial T}\right\|_V \frac{dv_r}{dZ} + \frac{1}{V_{an}}\left(Q_1 - Q_2 + W\sum_{j=1}^{3}(-\Delta H_j)\, r_j - H_{H_2} J_{H_2} A_m\right)$	
Mass balance in the permeate side $\frac{dF_{H_{2p}}}{dZ} = J_{H_2} A_m$	Heat exchanged in the reactor $Q_1 = U_1 A_1 (T_w - T_R) \quad ; \quad Q_2 = U_2 A_2 (T_R - T_P)$
The pressure drop in the catalytic bed $\frac{dP_R}{dZ} = -f\frac{\rho_r u_s^2}{d_p}$	Friction factor (Ergun's equation) $f = \frac{1-\varepsilon}{\varepsilon^3}\left(a + \frac{b(1-\varepsilon)}{Re}\right)$

and for $\Psi = 1 \Rightarrow i = H_2$.

The mathematical model considered real gases for thermodynamic properties calculations. Additional hypotheses adopted in the model development were: nonisothermal/nonisobaric, pseudo-homogeneous model, steady-state operation, plug-flow behavior was adopted for the permeate and reaction zone, nonexistence of boundary layer on the membrane and hydrogen diffusion in the membrane is the rate-determining step for hydrogen permeation.

The reactor dimensions used in this work were taken from Shu et al. (1994). All thermodynamic mixture properties were calculated using the Virial equation of state, with van der Waals mixing rules. The gases and the gaseous mixture viscosities were calculated by Chung's method (Poling 2004). The values of constants a and b of Ergun's equation are 150 and 1.75 respectively (Froment 1990). Other catalyst properties used were taken from Froment and Xu (1989).

Methane conversion and hydrogen recovery were defined as:

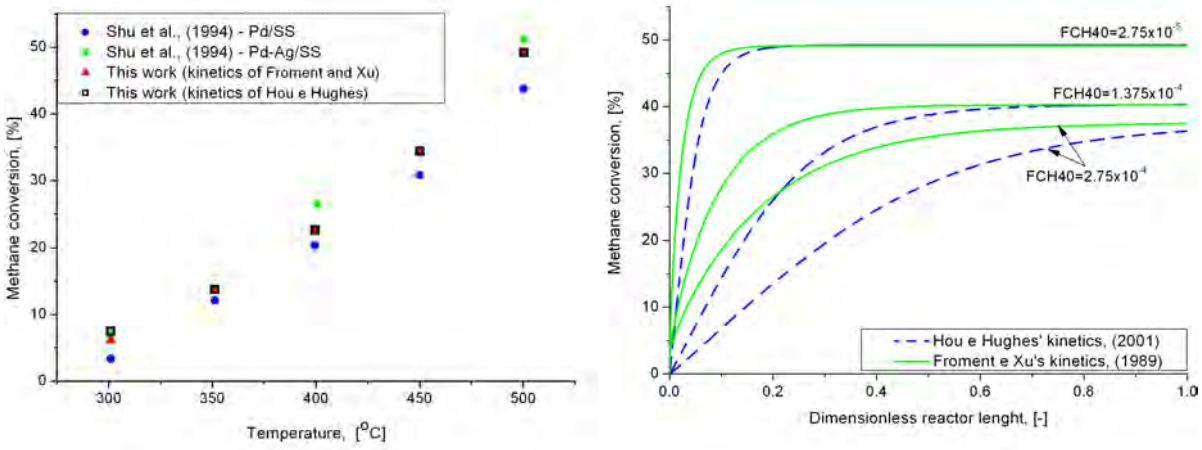
$$X_{CH_4} = \frac{F^0_{CH_4} - F_{CH_4}}{F^0_{CH_4}} \quad ; \quad Y_{H_2} = \frac{F_{H_{2p}}}{F_{H_{2p}} + F_{H_2}} \tag{4}$$

3 Results and discussion

3.1 Model Validation

Two different intrinsic kinetics available for the reactions of methane steam reforming were used. The first one is reported by Froment (1990) and it is the oldest and widely used. The second one, by Hou e Hughes (2001) is more recent and there is no reference about its use in a reactor model. The basic difference between them is that the first one was developed for catalysts of $Ni/MgAl_2O_4$ and only one of the products, the hydrogen, adsorbs on the surface. The second one was developed for catalysts of Ni/Al_2O_3 in which two products, hydrogen and carbon monoxide, adsorb on the surface. These two

kinetics were evaluated during the validation of the model, in this work. The validation of each model was carried out using given experimental data of a Pd-based membrane reactor reported by Shu et al. (1994) with the same design and operating conditions. Methane conversions obtained by the model were compared with the experimental ones reported by Shu et al. (1994). Methane conversions were evaluated for different steam to methane feed flow ratio, different operating temperatures and different operating pressures, and in this paper only a sample of the results are presented (Fig. 2 A)).



A) B)

Figure 2: Model validation. A) Methane conversions versus reactor temperature. B) Methane conversion profiles along the reactor.

The agreement between the simulated results and the experimental ones was good as it can be seen in the Fig. 2 (A). Moreover, the two available kinetics leads to similar results. The difference between them resides on their behavior along the reactor. As it can be seen in the Fig. 2 (B), methane conversion has an abrupt rise at the reactor beginning. This behavior is somewhat different when Hou's kinetics was used, and this difference increases as the methane feed flow rate increases. In other words, Froment's kinetics predicts an abrupt change for the composition at the reactor beginning, whereas the Hou's kinetics foresees a less sudden change. As it will be discussed further, molar methane feed flow rate less then $1 \cdot 10^{-4}\, mol/s$ cause dramatic changes the compositions at the reactor beginning, and as a result, the optimization using the gradient based optimization could not be performed for values smaller than $1 \cdot 10^{-4}\, mol/s$ of methane feed.

3.2 Parametric and gradient based optimization

At first, Froment's kinetics was chosen due to two mainly reasons. This kinetics is widely known and used, and also because it implies in less mathematical problems. Both kinetics demand products feed, the Froment's kinetics requires hydrogen feed and Hou's kinetics requires hydrogen and carbon monoxide feed. These problems are caused by the presence of the partial pressure of these components in the denominator of the rate equations. Therefore, low values were used ($1.0 \cdot 10^{-4}$) as initial conditions for these products. However, during the optimization using a gradient based method, the use of the Froment's kinetics cause failure of the algorithm. In this case, the lower admissible value for methane feed flow rate was $1.0 \cdot 10^{-4}\, mol/s$ and using the Hou's kinetics only.

To perform the optimization, a standard or reference operational condition for membrane reactors in methane steam reforming were taken according to Shu et al. (1994): PR0 = 136000 Pa, TW = 773.15 K, M = 3, FI = $2.75 \cdot 10^{-5}$ mol/s and FCH40 = $2.75 \cdot 10^{-5}$ mol/s.

3.3 Parametric optimization

In order to try to maximize methane conversion and hydrogen recovery, defined by Eqs. 4, different values around the standard parameters reported by Shu et al. (1994) were adopted. The lower and upper bounds were chosen based on operating characteristics of the membrane reactors and on the Shu's work. The upper and lower bounds are shown in Table 2. As it is shown in Fig. 3 A and B, an increase in

pressure, temperature and sweep gas flow cause an increase in methane conversion and hydrogen recovery. Conversely, an increase in methane conversion and hydrogen recovery is caused by a decrease in methane inlet flow. Particularly, an increase in steam to methane feed flow ratio (M) has an opposite effect on the methane conversion and hydrogen recovery. However, an increase in M causes an increase in the sum ($X_{CH_4} + Y_{H_2}$). Therefore, it can concluded that the use of the upper values of pressure, temperature and sweep gas and the lower methane feed value leads to the maximal methane conversion and hydrogen recovery, regardless of the interactions among the parameters. On the other hand, analyzing methane conversion and hydrogen recovery sum (Fig. 3 C), it can be noticed that the highest value for this parameter leads to the maximal methane conversion + hydrogen recovery. Indeed, the gain obtained in methane conversion, keeping the others parameters in the considered best conditions, is less than the setback obtained in the hydrogen recovery. Therefore, depending on the values of the other parameters, the trend of this effect change from an increase to a decrease in the objective (methane conversion plus hydrogen recovery). In other words, the interactions between the parameters are important in the optimization. Even so, high conversions (from 99.92 to 99.99%) and high recoveries (from 96.82 to 99.28%) could be achieved varying the steam to methane feed ratio and keeping the pressure, temperature and sweep gas at the highest values and the methane feed at the lowest value.

3.4 Optimization by a gradient based method (DIRCOL)

Having in mind the importance of the interaction between the parameters, it is imperative to perform the optimization taking into account these interactions. In order to carry out this task a gradient based algorithm of optimization (DIRCOL) was used (Von Stryk 2002). The optimization was performed directly from the differential equation by discretization. Therefore, the optimization problem was posed as:

Maximize: $X_{CH_4} + Y_{H_2}$,

Subject to:

- Model equations from Table 1;
- Parameters bounds from Table 2;
- Bounds of the state variables (for all state variables, the range is between 0 and 1 due to a normalization).

Due to a numerical instability in the optimizer's code the methane feed was kept in $1 \cdot 10^{-4} mol/s$, and the others parameters (PR0, TW, M and FI) were taken as variable decision. The optimization was carried out using the following input information supplied by the user: optimal tolerance and nonlinear feasibility tolerance equal $1.0 \cdot 10^{-3}$, *iscale* equal 0, initial grid points equal 15, with equidistant grid points, initial estimates for the parameters equal $PR0 = 506625.0\,Pa$, $FI = 1.375 \cdot 10^{-4}\,mol/s$, $TW = 873.15\,K$ e $M = 2.5$. The initial estimates for the state variables were based on a non linear fit on the integrated model. To avoid reaching local maxima, other initial estimates for the parameters were used, but all converged to the same values. The best parameters values are shown in Table 2. These parameters lead to a methane conversion of 96.27% and a hydrogen recovery of 91.26%, that are higher than 41.57% and 11.90% obtained in the adopted standard conditions changing methane feed from $2.75 \cdot 10^{-5}$ to $1.0 \cdot 10^{-4} mol/s$. It is important to emphasize that values lower than $1.0 \cdot 10^{-4} mol/s$ cause numerical instability, probably because the dramatic change in composition in the reactor beginning achieved for low values of methane feed, as can be seen in Fig. 3 D. This figure also shows the profiles of methane conversion along the reactor. It is also import to cite that this optimization could be carried out only with the Hou's kinetics, probably due to the fact that the Froment's kinetics lead to a more dramatic change in composition than the Hou's kinetics.

4 Conclusions

Comparing methane conversion obtained by the developed model using two available kinetics for methane steam reforming, it can be conclude that both characterize a good representation of the real reactor. However, the conversion profile obtained using Hou's kinetics describes smoother concentration profiles along the reactor. By parametric optimization, it was possible to obtain high conversions and recoveries (more

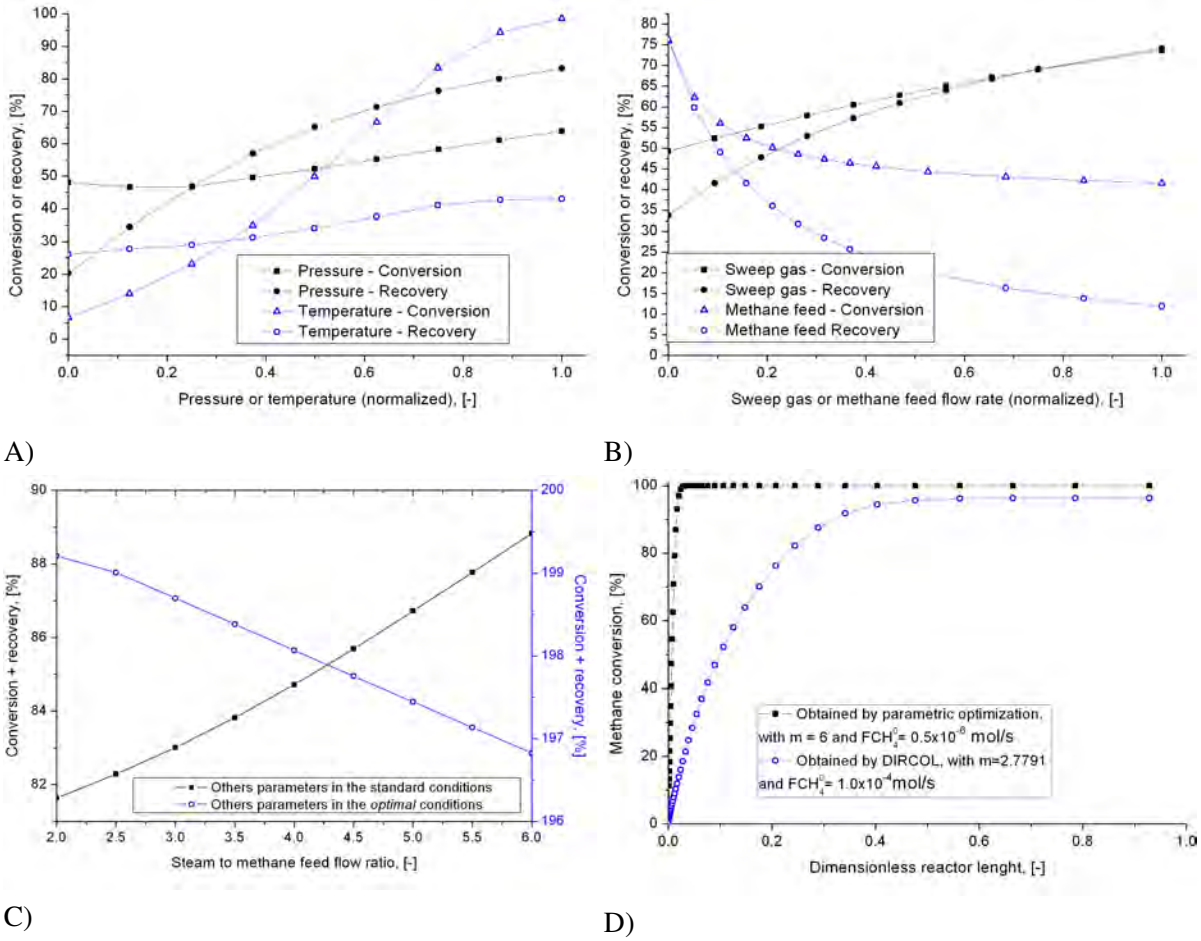


Figure 3: Parametric study (Graphics A-C) and profiles along the reactor obtained by parametric optimization and optimization with DIRCOL (D)

than 99 and 96 %) but, the best value could not be evaluated with assurance. The use of the DIRCOL to perform the optimization could only be possible with the use of Hou's kinetics in the model, even so for a value of methane feed of $1 \cdot 10^{-4} mol/s$. This value is about three times the standard value. A methane conversion of 96.27% and hydrogen recovery of 91.26% were obtained for the best parameters choice.

Table 2: Lower, upper bounds and best values of the parameters

Evaluation of redundant measurements on the air quality monitoring network of Lisbon and Tagus Valley

LEPAE, Departamento de Engenharia Química, Faculdade de Engenharia, Universidade do Porto, Rua Dr. Roberto Frias, 4200-465 Porto, Portugal.

Keywords: Principal component analysis, air quality, monitoring networks
Topic: Sustainable process-product development through green chemistry.

Abstract

The aim of this study was to evaluate redundant measurements in the air quality monitoring network (AQMN) of Lisbon and Tagus Valley (LTV). With this purpose, the minimum number of monitoring sites that should operate was achieved using principal component analysis (PCA). The air pollution data were colected in twenty monitoring sites during the period from January to December 2006. The air pollutants analysed were CO, NO_2, PM_{10} and O_3.

In this study, a different criterion for selection of the number of principal components (PCs) was applied. The PCs were selected representing at least 95% of the original data variance. Using this criterion, the PCs have more information about the air pollution data, increasing the confidence in the PCA results.

The PCA results showed that, from twenty studied monitoring sites, only ten for CO, eleven for NO_2, five for O_3 and nine for PM_{10} were needed to characterize the region. The air pollutant analysers corresponding to the redundant measurements can be installed in non-monitored regions, allowing the enlargement of the air quality monitoring network.

1 Introduction

The concerns about the negative effects of air pollution led to increased efforts to prevent and control the air pollution. As a consequence, the directives 1999/30/EC (EC Directive, 1999) and 2002/03/EC (EC Directive, 2002) defined the location of sampling points for the measurement of air pollutant concentrations. According to these directives, monitoring sites should be placed to provide data: (i) in areas within zones and agglomerations, where the population is likely to be directly or indirectly exposed to high concentrations (limit and target values were established as references); (ii) in other areas within zones and agglomerations which are representative of the general population exposure. However, redundant measurements of air pollutant concentrations should be avoid minimizing the costs relative to the management of the air pollutant analysers. Thus, the identification of the redundant measurements is an important task to be done for all AQMNs.

Principal component analysis (PCA) is a statistical method used for classification and regression tasks. It is a way of identifying patterns in data, finding their similarities and differences. The procedure started with the evaluation of the eigenvalues and eigenvectors of the covariance matrix of the standardized variables. The eigenvalues and eigenvectors are determined through the Equations 1 and 2, respectively.

$$\left|\mathbf{C}-\boldsymbol{\lambda}\mathbf{I}\right|=0 \tag{1}$$

$$\left(\mathbf{C}-\boldsymbol{\lambda}\mathbf{I}\right)\mathbf{T}=0 \tag{2}$$

[1] Corresponding author. Tel + 351-225081974. E-mail:fgm@fe.up.pt

where **C** is the covariance matrix of variables, **λ** is the vector of the eigenvalues, **I** is the identity matrix and **T** is the standardized weight values of each variable in the PCs (the eigenvectors). The PCs are then obtained, multiplying the original data set by the weights. Thus, PCs are linear combinations of the original variables and are orthogonal and uncorrelated to each other. They are obtained in such a way that the first PC explains the largest fraction of the original data variability, the second PC explains a smaller fraction of the data variance than the first one and so forth (Abdul-Wahab et al., 2005; Sousa et al., 2007; Wang and Xiao, 2004). To better clarify the influence of each original variable on the PCs, Varimax rotation is a rotational algorithm commonly applied to obtain the rotated factor loadings that represent the contribution of each variable on a specific PC.

PCA was recently applied for the identification of redundant measurements of air pollutant concentrations (Pires et al., 2008a, 2008b). Pires et al. (2008a, 2008b) applied PCA to identify similar air pollution behaviours in the AQMN of Oporto Metropolitan Area. According to these studies, only one monitoring site should operate in a region defined by a specific air pollution behaviour. Five air pollutants monitored at twelve sites were analysed. The results showed that only six monitoring sites should measured SO_2 concentrations, three for CO and NO_2 concentrations, and two for PM_{10} and O_3 concentrations.

The aim of the presented study was to evaluate redundant measurements in the air quality monitoring network (AQMN) of Lisbon and Tagus Valley (LTV), applying PCA to CO, NO_2, PM_{10} and O_3 concentrations data.

2 Data

The air quality data was collected from the monitoring sites integrated in the AQMN of LTV, managed by the Regional Commission of Coordination and Development of LTV, under the responsibility of the Ministry of Environment. The analysed air pollutants were CO, NO_2, PM_{10} and O_3 monitored in twenty monitoring sites: Alfragide (S1), Arcos (S2), Avenida da Liberdade (S3), Beato (S4), Camarinha (S5), Cascais (S6), Chamusca (S7), Entrecampos (S8), Escavadeira (S9), Laranjeiro (S10), Lavradio (S11), Loures (S12), Mem-Martins (S13), Odivelas (S14), Olivais (S15), Paio Pires (S16), Quebedo (S17), Quinta do Marquês (S18), Reboleira (S19) and Restelo (S20). Table 1 shows the main monitoring site characteristics, including the type and the main pollution sources associated to them (QualAr, 2008). The period considered was from January 2006 to December 2006. CO concentrations were obtained through non-dispersive infrared spectrometric method; NO_2 concentrations were monitored through chemiluminescence; PM_{10} concentrations were obtained through beta radiation attenuation; and O_3 concentrations were monitored by UV-absorption photometry (EC Directive, 1999, 2002). The monitoring was continuous and hourly averages were

(concentrations expressed in μg m^{-3}). All the equipments were submitted to a rigid maintenance program, being periodically calibrated.

The data were organized in such a way that each column had the hourly average concentrations of a specific air pollutant at a specific monitoring site. To be possible to apply the PCA, the pollutant concentrations must be available at the same time in all monitoring sites. Thus, the lines with missing data were removed from the analysis. Concentrations were Z standardized to have zero mean and unit standard deviation.

3 Results and Discussion

PCA was applied as a classification method to group monitoring sites with redundant measurements of air pollutant concentrations during the analysed period. The first step to apply this method is the selection of the number of PCs. Kaiser criterion, which selects PCs with eigenvalues greater than 1, is commonly used for this purpose (Yidana et al., 2008); as this criterion do not usually achieve 95% of the original data variance (Mendiguchía et al., 2004; Pires et al., 2008a, 2008b), in this study, a different criterion (ODV_{95}) was also used, aiming to select PCs representing at least 95% of the original data variance; this procedure allowed to obtain more information about original data contained in the selected PCs and to increase the confidence in the PCA results.

Table 2 shows, as an example, the main results (rotated factor loadings, eigenvalues, variance and cumulative variance) of PCA application to PM_{10} concentrations data. Considering ODV_{95} criterion, the first nine PCs need to be taken into account for analysing the PM_{10} concentrations. The factor loadings represented both how the original variables are weighted for each PC and the correlation between the original variables and the PCs. Varimax rotation was the rotation algorithm used to maximize the squared loadings of the columns, obtaining the rotated factor loadings. Therefore, each PC presents high loadings for some variables and low loadings for others, facilitating the interpretation of the PCs in terms of the original variables. The rotated factor loadings in bold indicate the original variables that mostly influence the correspondent PC. Thus, PC1 had important contributions of S8, S10, S14 and S15 sites, while PC6 was heavily loaded by S5 and S17 sites. PC8 had important contributions of S13, S18 and S19 sites. S11, S7, S6, S3, S12 and S9 sites were significantly associated with PC2, PC3, PC4, PC5, PC7 and PC9, respectively. The monitoring sites grouped in the same PC presented redundant measurements. Thus, only nine monitoring sites should measure the PM_{10} concentrations.

Figure 1 shows the location of the monitoring sites and the results of the PCA application to the concentrations of all air pollutants. The groups of monitoring sites with redundant measurements can be explained by the location of emission sources and the variability of the wind direction as it was explained in our previous studies (Pires et al., 2008a, 2008b). As a rural site, S7 presented a specific pollution behaviour. Thus, it was not coupled with other sites. The monitoring sites in Setúbal city (S2, S5 and S17) presented redundant measurements due to their proximity. Thus, the geographic location of the monitoring sites was also important in the formation of the groups of monitoring sites. Despite the geographic proximity to other monitoring sites, S3 site presented different air pollution behaviour for NO_2 and PM_{10}. This site is highly influence by traffic, presenting the highest concentrations of these air pollutants.

Concluding, from the twenty studied monitoring sites, only ten for CO, eleven for NO_2, five for O_3 and nine for PM_{10} were needed to characterize the region. The air pollutant analysers corresponding to the redundant measurements can be installed in non-monitored regions, allowing the enlargement of the air quality monitoring network.

Figure 1. Location of monitoring sites and the PCA results using: (a) CO concentrations data (CO concentrations were not measured at S7 site); (b) NO_2 concentrations data (S19 site did not present 75% of the annual data); (c) PM_{10} concentrations data (PM_{10} concentrations were not measured at S2, S4 and S16 sites; S1 and S20 sites did not present 75% of the annual data); (d) O_3 concentrations data (O_3 concentrations were not measured at S3, S6, S11 and S17 sites).

4 Conclusions

This study aims the identification of redundant measurements in AQMN of LVT through the application of PCA. PCA was applied as a classification method, coupling the monitoring sites with redundant measurements.

The results showed that, from twenty studied monitoring sites, only ten for CO, eleven for NO_2, five for O_3 and nine for PM_{10} were needed to characterize the region. The air pollutant analysers corresponding to the redundant measurements can be installed in non-monitored regions, allowing the enlargement of the air quality monitoring network.

Keywords: Data reconciliation, Kalman filters, MHE approach, Gross Error Detection
Topic: Systematic methods and tools for managing the complexity.

Abstract

The purpose of this work is to compare dynamic data reconciliation estimators and algorithms for detecting gross errors. Also is proposed a methodology for measure the performance of the algorithms. The problem of dynamic data reconciliation is treated using five different Kalman filters formulations and a moving horizon estimator approach. The estimators are compared using a nonlinear dynamic example, in transient scenarios. The problem of gross error detection and bias estimation is also treated using two different algorithms combined with the global test: The Generalized Likelihood Ratio (GLR), proposed by Narashiman and Mah (1988), and a bias detection method, proposed by McBrayer and Edgar (1995). The data reconciliation results show there are not significant differences in quality of the reconciled states obtained by the different estimators. On the other hand, the time spent in the data reconciliation step differs significantly among the estimators. The implementation of the proposed gross error detection strategies shows the GLR is simpler and less computation time spending than the algorithm proposed by McBrayer and Edgar. In this work is showed an alternative implementation of the combined use of the global test and the GLR which consists in evaluating the global test for a finite number of times and not in a cumulative way, as proposed in the original GLR.

1. Introduction

A real-time on-line optimization provides set-points to the distributed control system and therefore maintains the process near its optimum operating conditions. This optimization requires an accurate process model and reconciled process data needful to specify the current status of the plant model and to estimate model parameters for plant-model matching. The main goal of data reconciliation is to adjust process measurements with random errors by having them satisfy material and energy balance constraints. During the data reconciliation it is natural to assume the presence of random, normally distributed errors with zero mean and known variances, to be present in the process data. However, a different type of error – gross error – sometimes is present in the data. The presence of gross error invalidates the statistical basis of data reconciliation procedure. When flawed information is used for state estimation and process control, the state of the system is misrepresented and the resulting control performance may be poor and can lead to suboptimal and even unsafe process operation because the reconciled values will exhibit '*smearing*' when compared with the true values (Liebman, Edgar & Lasdon, 1992). The elimination of less-frequent gross errors is achieved by gross error detection techniques. The purpose of this work is to compare dynamic data reconciliation estimators and algorithms for detecting gross errors. The problem of dynamic data reconciliation is treated using five different Kalman filters formulations and a Moving Horizon Estimator (MHE) approach. The estimators are compared using a nonlinear dynamic example, in transient scenarios. The Kalman filters formulations are (Salau et al., 2007): Extended (EKF), Constrained Extended (CEKF), Discrete Extended (DEKF), Modified Discrete Extended (MDEKF), and Continuous Extended (CtEKF). The MHE formulation is similar to a nonlinear model-predictive control (NMPC). The main difference between those algorithms is the NMPC optimizes and predicts forward in time,

while MHE optimizes and smoothes backward in time. Additionally, in the MHE, the estimates of the past measured state and input variables over finite history horizon are adjusted to optimally satisfy the modeling equations. The problem of gross error detection (GED) and bias estimation is also treated using two different algorithms combined with the global test: The GLR, proposed by Narashiman and Mah (1988), and a bias detection method, based on the moving horizon strategy, proposed by McBrayer and Edgar (1995). The algorithms were compared using the five different Kalman formulations. Moreover, an alternative implementation of the combined use of the global test and the GLR, which consists in evaluating the global test for a finite number of times and not in a cumulative way, as proposed in the original GLR, is presented.

2. Problem Formulation

Consider the dynamic systems represented by nonlinear differential-algebraic equations as shown below:

$$\dot{x}(t) = f[x(t), u(t), t, p(t)] + w(t) \qquad y(t) = h(x(t), u(t), t) + v(t)$$

Where x denotes the states, u the deterministic inputs, p the model parameters, and y the vector of measured variables. The process-noise vector, w(t), and the measurement error, v(t), are assumed to be a white Gaussian random process with zero mean and covariance Q(t) and R(t), respectively.

In the formulations, the matrices Q and R are the tuning parameters for reconciling the model with the process measurements and their statistical significance are a measure of confidence in the model and in the process sensors, respectively.

3. The Estimators formulations

The extended Kalman filter has been the most widely-used technique for nonlinearly-constrained weighted least-squares estimation problems. The EKF formulations (Table 1) use local linearization to extend the scope of the Kalman filter to systems described by nonlinear ordinary differential equations. The advantages of the EKF formulations are their simplicity, the recursivity of the algorithms, and their modest computational load. These formulations are suitable for real-time industrial-scale applications (Becerra et al., 2001). On the other hand, the main advantages of the moving-horizon approach over the extended Kalman filter are its capability of handling path constraints on the variables and its flexibility with respect to the choice of the estimation criterion. Its disadvantage is, for on-line implementation, the high computational load for large estimation horizons.

MHE	$\hat{x}_i^- = \hat{x}_{i-1}^+ + \int_{t_{i-1}}^{t_i} f(\hat{x},u,t)dt = F(x_{i-1},u_{i-1})$ Where i=(k-N),..K $x(0) = x_0$ $\hat{y}_i^- = h(\hat{x}_i^-)$	$\min_{\hat{w}_{k-N-1},..\hat{w}_k,\hat{v}_{k-N},..,\hat{v}_k} \left\{ \psi_k = \left(\hat{w}_{k-N-1}^+\right)^T \left(P_{k-N}^-\right)^{-1} \left(\hat{w}_{k-N-1}^+\right) + \right.$ $\left. + \sum_{j=k-N}^{k} \left(\hat{v}_j^+\right)^T R^{-1} \left(\hat{v}_j^+\right) + \sum_{j=k-N}^{k} \left(\hat{w}_j^+\right)^T Q^{-1} \left(\hat{w}_j^+\right) \right\}$ St to: $\hat{x}_{k-N}^+ = \hat{x}_{k-N}^- + \hat{w}_{k-N-1}$, $\hat{x}_{j+1}^+ = F(\hat{x}_j^+) + \hat{w}_j$ $j = k-N,..,k-1$ $y_j = h(\hat{x}_j^+) + \hat{v}_j$, $\hat{x}_{min} \le \hat{x}_j^+ \le \hat{x}_{max}$ $j = k-N,..,k$

4. Gross Error Detection Strategies

The treatment of gross errors can be divided into three stages. In the first stage, gross error detection is performed to certify whether gross errors are present in the measurements or not. If the presence of gross errors is detected, the next stage is the identification of the sources of those errors. The final stage is the elimination of the gross errors. The global test was introduced by Ripps (1965) and its conclusion that no bias is present obviates the identification of gross error location. The global test was used combined with the GLR strategy, as the first indicative of the presence of gross error. The complete algorithm can be found in Narashiman and Jordache (2000). The GLR is based on the maximum likelihood ratio principle used in statistics. The main advantage is the GLR test is capable of identify different types of gross errors. The complete algorithm can be found in Narasimhan and Mah (1988). Another algorithm used in the present work was tailored for using with MHE approaches. The gross error detection and estimate are made by a different data reconciliation problem. The objective function includes the gross error as a parameter. The complete algorithm can be viewed in McBrayer and Edgar (1995), which has a questionable assumption by using the criterion of 30% difference between the base case and the measurements.

5. Case of study

The case of study presented in this work is a reactor where an exothermic irreversible reaction is taking place in a continuous stirred tank reactor. The modeling equations in dimensionless form are given by (Limqueco and Kantor, 1990). The nominal parameter values are shown in Table 2**Error! Reference source not found.**.

$$\frac{dx_1}{d\tau} = -\phi x_1 k(x_2) + q(x_{1f} - x_1) \qquad \frac{dx_2}{d\tau} = \beta \phi x_1 k(x_2) - (q+\delta)x_2 + \delta u + q x_{2f}$$

Where x_1 is the dimensionless concentration, x_2 is the dimensionless temperature and u is the dimensionless cooling jacket temperature.

Table 2. Model Parameters

Parameter	ϕ	β	δ	γ	q	x_{1f}	x_{2f}	x_{1S} (ss point)	x_{2S} (ss point)
Value	0.072	8	0.3	20	1.0	1.0	0	0.856	0.885

The algorithms and the simulations were implemented in MATLAB 5.3. The integration algorithm was *ode*15*s* and the nonlinear optimization was solved by using the function *fmincon*.

6. Results and Discussion

Initially, the performances of the estimators were compared. The model was subjected to disturbances in the input concentration x_{1f}. The disturbances and the simulated outputs,

without noise, can be viewed in the Figure 1. After the simulation, white random noises, with known variances were added to the outputs and then given as the measurements for the estimators. The used estimators' parameters are listed in Table 3.

Table 3. Estimators parameters

$$Q = \begin{bmatrix} 1e\text{-}4 & 0.2e\text{-}4 \\ 0.2e\text{-}4 & 0.2e\text{-}4 \end{bmatrix} \qquad R = \begin{bmatrix} 2.4e\text{-}4 & 0 \\ 0 & 2.4e\text{-}4 \end{bmatrix}$$

Parameter	Sample Time (Δt)	Qd	Rd	White noise variance	MHE horizon
Value	0.25	(Q × Δt)	(R / Δt)	2.4×10^{-4}	5

The results were obtained after a set of 10 runs, with different random noises added into each run. The data reconciliation results for all estimators are shown in Figure 2 and Figure 3.

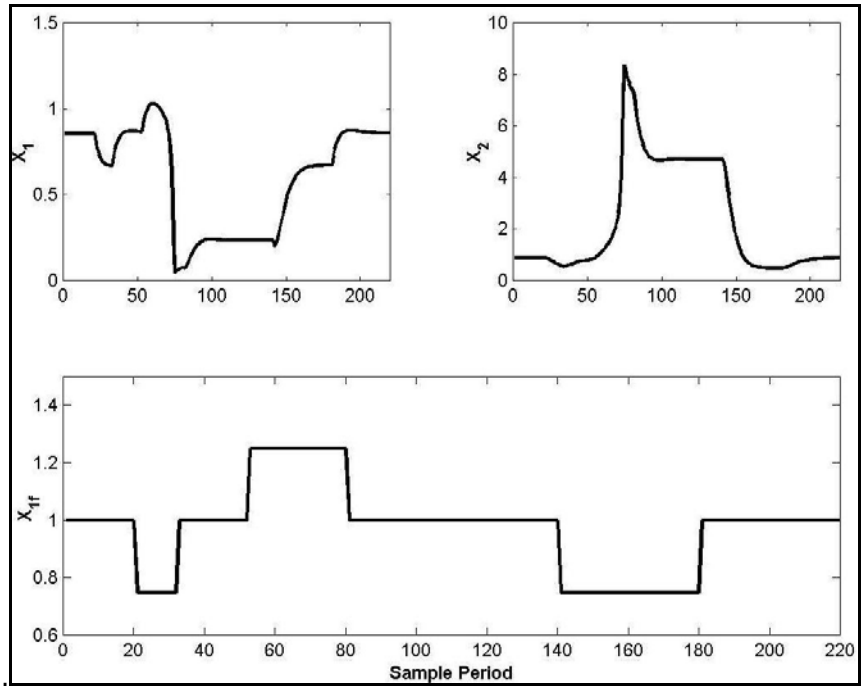

Figure 1. Input disturbances in X_{1f} and Outputs simulated variables

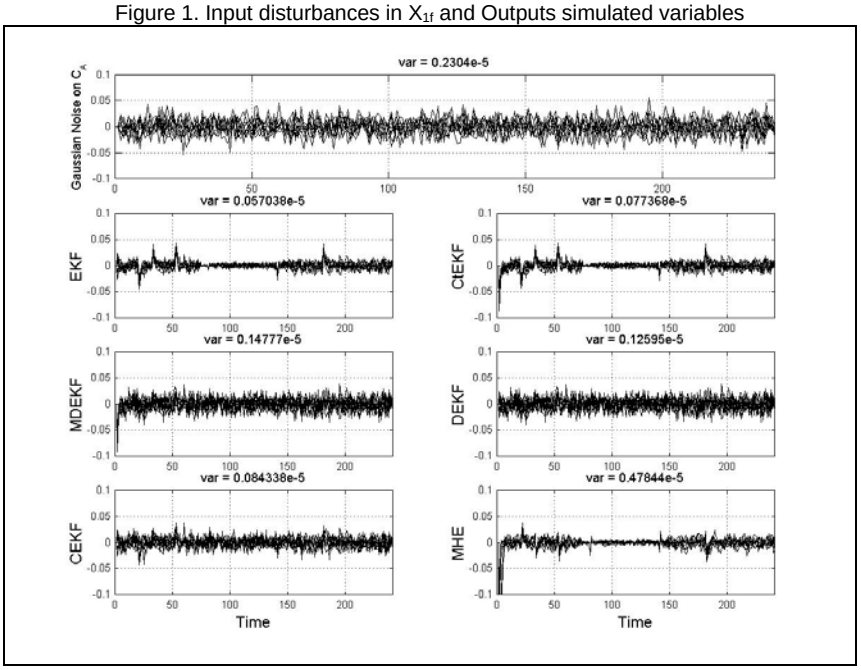

Figure 2. Difference between the reconciled variable X_1 and the measured variable X_1, for all estimators.

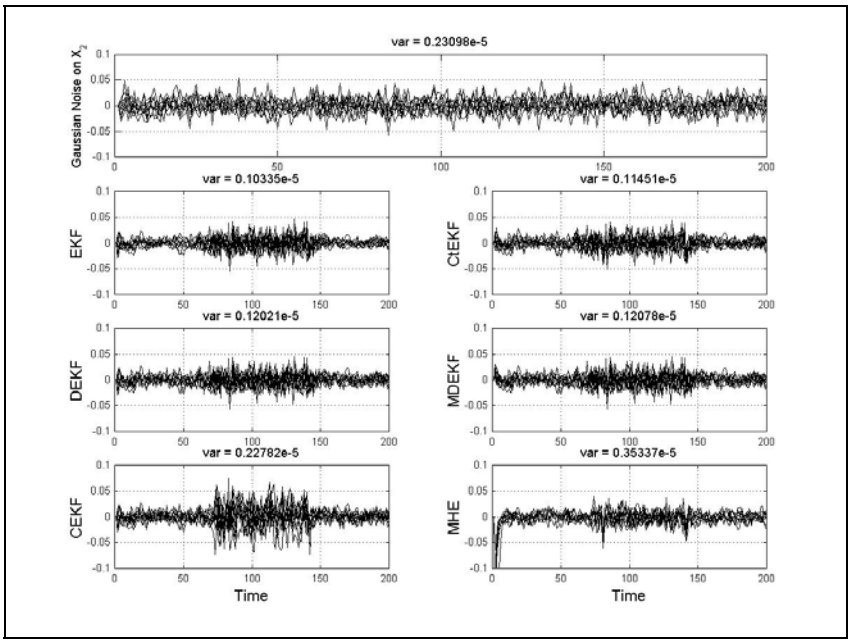

Figure 3. Difference between the reconciled variable X_2 and the measured variable X_2, for all estimators

All estimators, excluding MHE, have shown different attenuation degrees, which can be proved by the variance shown in each figure. Comparing among all estimators, the EKF have shown the best performance based on noise attenuation. The noise variance has been reduced in 75% for concentration and 55% for temperature. In Table 4, the noise attenuation percentages related to the measured variables are shown. It is important to notice that exist a relationship between the nonlinearity of the model (in different operation points) with the quality of the reconciliation in each variable. Hence, there is a variable attenuation degree related with the operating point. The estimators which strongly have shown this behavior are: EKF, CEKF, CtEKF, and MHE. The estimators MDEKF and DEKF have shown stability related to this behavior with a small modification in the noise variance to different regions. This is due to the discrete form of prediction of the error covariance matrix in these two formulations.

The gross error detection tests were performed for scenario where a bias of -0.08 was added in x_1. The confidence degree of the global test was 95% and the bias value was chosen to ensure that this value would be out of this region. The MHE was not tested due to its high computational time.

Table 4. Noise attenuation percentage for all estimators

Table 5. Computing time for all estimators

Estimator	Proposed GLR	McBrayer and Edgar
EKF	57.39	452.95
CtEKF	56.12	448.12
CEKF	70.23	474.71
DEKF	50.41	408.18
MDEKF	50.32	391.93

The implementation of the proposed gross error detection strategies shows the GLR is simpler and less computation-time spending than the algorithm proposed by McBrayer and Edgar (1995). In Table 5 is shown the comparison of computing time between all the sets (estimators + detector algorithms). The set MDEKF + GLR has presented the best performance. Figure 4 shows the result for the gross error detection problem with a bias in x_1.

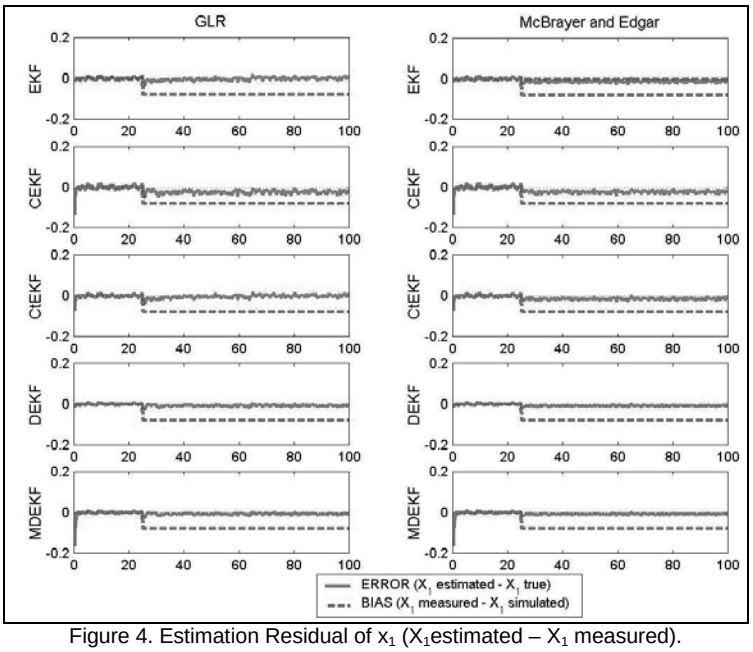

Figure 4. Estimation Residual of x_1 (X_1estimated – X_1 measured).

It can be observed in Figure 4 that all the sets have presented similar good results, eliminating the bias and providing good reconciled values. Only the CEKF have presented a biased estimative.

7. Conclusions

- The EKF is the best formulation to reduce noise variance and MDEKF presents the best cost/benefit because its easy implementation and stability related with the linearization and
- The MHE did not present noise attenuation and has excessively high computational time to be used with on-line applications.
- GLR was the best GED strategy based on the criterion: performance versus computing time and Global test is useful and should be included in the McBrayer and Edgar's algorithm replacing the criterion of difference between the base case and the measurements to detect gross errors.
- Both gross error detection and estimation algorithms have obtained a good estimate of the bias.

Topic: Sustainable process-product development through green chemistry.

Abstract

Composting is an attractive technology for diverting solid organic waste from landfill disposal. Furthermore, compost allows the improvement in nutrients content and soil structure. However, different quality compost can be obtained depending on the origin of its raw materials (urban residues, grass and forest residues, sludge, etc.). In some cases, the presence of heavy metals may become a source of risk in a long-term scenario of compost application for crop production.

In this work, an environmental risk assessment of compost application for agricultural crop production was carried out considering the heavy metal (Cu, Cr, Cd, Pb, Ni and Zn) content of different types of compost (green, green mixed with sewage sludge wood residues, organic urban waste, etc). Accumulation and biotransfer of heavy metals to the food chain, as well as the final human exposure by different pathways, was estimated by a multicompartmental model considering a number of temporal horizons (5 to 100 years) of compost application. In general, the hazard indexes (HI) obtained for the considered scenarios were quite low. Thus, it can not be considered as a direct risk source to human health. However, in some cases HI reached values around 0.5, what suggested that a more precautionary attitude should be adopted towards this practice, specially bearing in mind that soil pH has an important contribution to uncertainty, so this behaviour could be modified if compost was applied in other scenarios with different soil characteristics and pluviometry.

1 Introduction

Composting can be defined as a humification process of the organic matter under controlled conditions and in absence of soil resulting in compost. Compost acts as a bearer of nutrients to the soil, improving its structure and helping to reduce the erosion and the absorption of water and nutrients by plants. It offers a number of advantages in comparison with other mechanisms of elimination of residues. However, European legislation has become more restrictive with the priority pollutants content in residues that can be used as raw materials in the production of fertilizers (European Commission, 1999; European Commission, 2001). The restrictions stated regarding the quality of raw materials employed for the compost manufacture, and the compost itself, affects the use of compost as fertilizer in agriculture, as well as the kind of raw material that can be used.

Nowadays, there are diverse types of compost, which are characterized by the origin of its raw materials: urban residues, grass and forest residues, wastewater treatment sludge, other organic residues, and mixtures of them. Depending on the raw material, the presence of

* Corresponding author. Tel + 34-981-563100 Ext. 16772. E-mail: millicg@usc.es

potentially toxic elements (PTEs) for the human health and the environment (persistent organic pollutants – POPs - or heavy metals) may become important (Rojas, 2004).

Variations in some toxic metal concentrations contained in compost (Cd, Cr, Pb, Ni, Zn, Cu among others) have been detected, in some cases exceeding the thresholds values for these parameters (Greenway and Song, 2002). Consequently, in a long-term application scenario, compost for the production of agricultural crops must be controlled by certain procedures. The presence of high concentrations and the possible chemical and physical associations occurring in natural systems can cause the accumulation of heavy metals in soil, and it may pose a risk since they can be transferred to the food web. Environmental Risk Assessment could help on establishing safety conditions for compost application for agricultural crops and pasture production (Franco et al, 2006). In this sense, the considered mechanisms of transfer, accumulation and exposure take great importance in the estimation of human exposure to heavy metals transferred from the applied compost.

In this work, an incremental environmental risk assessment for the application of different types of compost for agricultural crop production was carried out considering the heavy metals (Cu, Cr, Cd, Pb, Ni and Zn) content. Exposure doses were calculated applying a multicompartmental model and later compared to reference doses to obtain the corresponding hazard quotient for the considered scenarios. A sensitivity analysis was also carried out to evaluate the contribution of the different variables considered in the model to uncertainty.

2 Materials and Methods

Characterization of the Scenario

The Environmental Risk Assessment (ERA) for the application of compost containing heavy metals as fertilizer in the production of agricultural crops (corn and garlic) and pasture was carried out. A conceptual model for the scenario of application of compost can be seen in Figure 1.

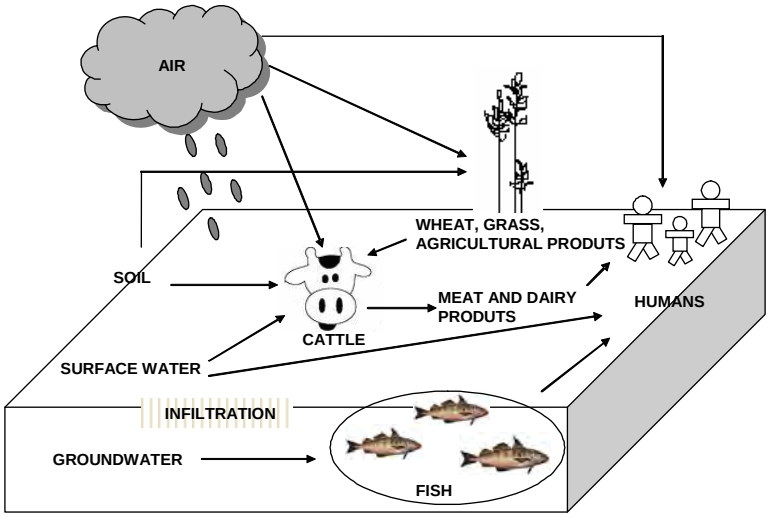

Figure 1. Conceptual model for the Environmental Risk Assessment.

Fertilizers of different characteristics (five types of compost, mineral-N as fertilizer and a mixture of 50% mineral-N with 50% of compost) found in the literature (Greenway and Song, 2002; Rosal et al, 2007) were used for this risk assessment, as well as reference limits from Spanish legislation for different compost quality (A, B and C). They have been named as C1 (Grass and Leaves), C2 (Mixture of Green and Sludge Waste), C3 (Vegetable Waste), C4

(Wood Waste), C5 (Municipal Solid Waste MSW), C6 (N-Mineral) and C7 (50% C5 – 50% C6). Table 1 shows heavy metal content in the different fertilizers and precipitation rates in the studied area.

Table 1. Heavy metal content in compost and precipitation rates for the considered scenarios

Compost / Law thresholds	Excessive precipitation (m^3/year)	Precipitation rate (m^3/year)	Heavy metal concentration (mg/kg)					
			Cd	Cu	Cr	Ni	Pb	Zn
C1 (Grass and Leaves) [(a)]	0.945		1.5	50.2	23.9	15.0	117.2	220.4
C2 (Green and Mixed Waste Sludge) [(a)]		2.7	3.2	140.3	30.3	16.5	133.5	354.6
C3 (Vegetable Waste) [(a)]		2.7	0.20	10.8	9.0	5.8	13,7	25.9
C4 (Wood Waste) [(a)]		2.7	0.18	10.7	8.6	5.7	17.3	35.8
C5 (Municipal Solid Waste – MSW -) [(b)]	0.1857	2.7	1.5	25	32	20	42	33
C6 (N-Mineral) [(b)]		0.58	1.3	20	29	20	39	28
C7 (50C – 50M) [(b)]		0.58	1.5	24	21	22	36	32
RD 824/2005-A [(c)]	0.945	2.7	0.7	70	70	25	45	200
RD 824/2005-B [(c)]		2.7	2	300	250	90	300	500
RD 824/2005-C [(c)]		2.7	3	400	300	100	200	1000

(a) Greenway and Song (2002)
(b) Rosal et al (2007)
(c) Spanish Government (2005)

Composts C5 to C7, were applied in agricultural soils in which rotatory crops of wheat-garlic-wheat were cultivated.

Apart from heavy metal concentration in compost, other data are necessary to carry out an environmental risk assessment of the application of compost, like soil properties or application rates (Table 2). Thus, using the information provided by the studies above mentioned, potential risks on human health (including possible carcinogenic effects) derived from the presence of various metals were assessed. The analysis was carried out in different temporal horizons (3, 5, 10, 50 and 100 years). Different exposure pathways like intake of meat, milk, wheat and water, inhalation and skin contact were considered, as well as other influencing factors like the exposure time.

To predict metal concentrations in soil, three equations were employed for each metal: a mass balance model for the proper estimate of metal accumulation in soil, and two multi-correlation models to estimate the uptake by plants from soil and the free metal concentration in soil solution. The exposure model was constituted by six equations, two of them being food-chain models for the estimation of metal concentration in the meat and milk of cattle. The remaining equations were employed to assess human exposure through the pathways considered: 1) ingestion of cattle meat and milk, 2) ingestion of soil, 3) inhalation of soil, 4) dermal contact with soil, and 5) ingestion of wheat. The latter route was considered only for the data of Rosal et al (2007).

Table 2- General characteristics regarding compost application.

Compost		**Source**
- Application rate	7.5 m^3/ha·year	Rosal et al, (2007)
Soil		
- Initial HM concentration	0.23 mg/kg	Franco et al, (2006)
- O.M.	36%	Rosal et al, (2007)

Estimation of Hazard Quotients

The quantification of the potential non-carcinogenic risk was obtained through the determination of a Hazard Quotient (HQ), which was calculated dividing the individual doses of each metal by its Reference Dose (RfD). Carcinogenic effects were evaluated multiplying the estimated dose by a Slope Factor. In this study, the oral, inhalation and dermal routes were considered. However, studies involving different routes of exposure were not always available. Thus, route-to-route extrapolations were needed when no specific dose-response data were present. Values of the HQ lower than 1.0 are considered as indicative of acceptable risk.

The HQ was calculated using equation [1]:

$$HQ = ExpD / RfD \quad [1]$$

where ExpD represents the individual estimated exposure dose for each metal. When aggregating the HQ corresponding to the different metals, the Hazard Index (HI) is obtained for each compost.

Biotransfer model

For estimates regarding the biotransfer of metals, equation [2] was applied:

$$Cx = (Cp \cdot PIRx \cdot fm + Cs \cdot SIRx + Cw \cdot WIRx) \cdot BTFx \quad [2]$$

where Cx is the concentration of metals accumulated in meat or milk ($mg \cdot kg^{-1}$). Cp is metal concentration in crops ($mg \cdot kg^{-1}$), PIRm is crops ingestion rate ($kg \cdot day^{-1}$), fm is the fraction of food that comes from the area, Cs is metal concentration in soil, SIRm is soil ingestion rate ($kg \cdot day^{-1}$), Cw is metal concentration in water ($mg \cdot l^{-1}$), WIRm is water ingestion ($l \cdot day^{-1}$) and BTFm is a biotransfer factor for meta or milk ($day \cdot kg^{-1}$), which is specific for each metal (U.S.EPA, 1989).

Sensitivity analysis

Monte Carlo simulations, a technique that allows a numerical simulation propagating the uncertainty of the parameters under the distributions stated, were done using the software Crystal Ball (5000 iterations employed). In this was, the appraisal of the influence of the different variables in the hazard index estimate was carried out.

3 Results

In Figure 2 the estimated HI is represented for the considered composts and scenarios. According to this figure, it can be noticed that compost made from vegetable waste (C3) and wood waste (C4) present the lowest HI in all cases. On the other side, the HI calculated for composts C5 to C7 were significantly higher and even exceeded the limits permitted by the Spanish legislation when compost was applied during 50 or 100 years. These results can be

attributed to the high content of heavy metals present in these types of compost. Thus, it was observed that the application of compost manufactured with green raw materials would be safer than employing those made from MSW.

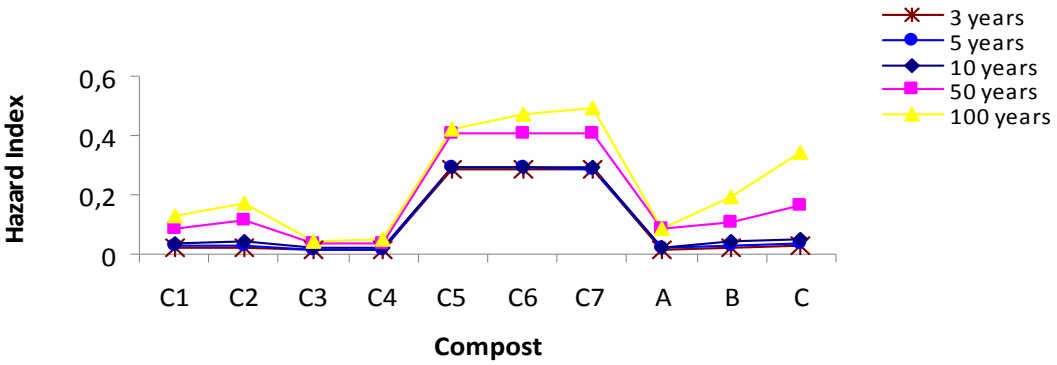

Figure 2. Hazard Index estimates.

Table 3 summarizes the main results obtained in the sensitivity analysis of the HI associated to the application of MSW compost (C5). The compost application rate presents the major influence in the variability of the HI. The pH and organic matter content in soil also showed an important contribution. Organic matter serves as an important ligand to metals. In particular, dissolved organic matter (DOM), being the most mobile and biologically active soil organic fraction, increases the bioavailability and mobility of trace elements in the soil, while insoluble organic complexes can effectively remove metals from the solution and thus reduce their ecotoxicity (Strobel et al, 2005). Low pH favours solubility, and hence mobility, and in addition, complexation by OM may enhance the solubility of heavy metals and thus its transfer to the food chain, increasing the HI. This is in accordance to the results obtained in the sensitivity analysis.

Table 3. Sensitivity analysis: main contributions to uncertainty in HI for the scenario of MSW compost (C5).

Parameter	**%**
Application rate	19.8
Time	12.8
Soil pH	-8.5
Initial heavy metal concentration in soil	3.3
O.M.	3.2
Precipitation rate	2.9

4 Conclusions

The application of compost as organic fertilizer for agriculture is promoted for the reduction of solid waste and chemical fertilizers use. The application of compost to agricultural crops is an ecological alternative; however, in some cases, the metals present in the compost can be released into the soil, water and plants and therefore they can be biotransfered to livestock and subsequently being a source of environmental risk. The sensitivity analysis gave as main result that compost application rate, pH and OM had an important influence in the HI obtained. Therefore, the definition of the scenario parameters is a key factor in determining the final fate of metals and thus, extrapolation may lead to important errors.

Keywords: REACH, Chemical risk, Safety, QSAR's
Topic: Systematic methods and tools for managing the complexity.

The European Parliament approved on the 16th of December 2006 the Regulation (EC) No. 1907/2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals commonly known as the REACH regulation.

The REACH text took about 6 years before its final shape, all of them full of intense discussions and polemic. Today, it represents a dramatic change in the way the risk from chemical substances to the human health and the environment is approached by the authorities and the enterprises in the European Union, having replaced more than 40 directives.

But besides its strict regulamentary purpose, REACH has the objectives stated in its Article 1(1) of promoting "alternative methods of assessment of hazards of substances" and "enhancing competitiveness and innovation".

For these objectives to be attained it is useful to know REACH if not in detail at least in its general structure and processes, understanding in which directions the legislation points needing new developments and better knowledge.

REACH besides contributing to the collection of an huge amount of data for later exploitation, will provide through its dissemination of information mechanism an early alert that can be useful to focus research efforts on specific substances, on its characteristics and uses.

We will explain in what ways REACH will promote those goals and what are the concerned areas of scientific research, among them the replacement of substances of very high concern by safer new ones, the development of new testing methods and the use of QSARs.

Introduction

The European Parliament approved on the 16th of December 2006 the Regulation (EC) No. 1907/2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals commonly known as the REACH regulation.

This Regulation represents an important change in the EU policy for chemical substances moving to those who produce and to those who place the chemical substances on the market the responsibility and the burden for making evidence that human health and environment are protected.

This is done through the registration of each substance that each enterprise manufactures or imports above 1 ton/yr. To make the registration the enterprises will have to provide scientifically founded information on the intrinsic properties of the substance and - taken in consideration the hazardous ones - on the risk management measures taken to control the risk.

The Regulation come out in the middle of an intense discussion mainly derived from the fact that the costs for gathering the information and making the tests to obtain them whenever

* Corresponding author. Tel + 351-21-0924758. E-mail:joao.lourenco@ineti.pt

they are not available will lay upon the enterprises together with a fee that has to be paid with the registration.

The more important enterprises under the umbrella of their european associations, namely the CEFIC for the chemical industry, stimulated by the systematic consultations that took place during the development of the law, understood their interest in cooperating with the European Commission in order to obtain a final balanced text.

Innovation driven Regulation

Besides its strict regulamentary purpose, REACH states as objectives in its Article 1(1) promoting “alternative methods of assessment of hazards of substances” and “enhancing competitiveness and innovation”.

As a matter of fact several dispositions of the law invite the scientific community to be attentive to the evolution of the tools and methodologies involved in REACH and to the needs arised by changes and threats in the market caused by the enforcement of the Regulation.

Alternative methods of assessment of hazards of substances

Some Regulation related obligations are stated in its text that encourage the development of new methods of assessment of hazardous substances. In REACH those obligations are the ones derived from the objective of avoiding as much as possible the sacrifice of vertebrates associated to some tests as explicitly stated in its Article 13. This is done not only through the mechanisms implied in the registration that make mandatory sharing registration data and submit testing proposals with vertebrates to the Agency before their execution, but by the use of *in vitro* methods, qualitative or quantitive structure-activity relationship models ((Q)SARs) or from information from structurally related substances (grouping or read-across) to estimate the substance properties.

Also improvement of testing methods seeking that they are exact and accurate as well as low cost and effective contributors for the main goal of identifying and assessing the hazards of the substances is a continuously open field for research of new methods and revision of existing ones.

At the present about 40 testing methods are currently under development or revision. New methods that may be proposed in a near future are, among others, vapour pressure determinations, determinations of the partion coefficient n-octanol/water using a HPLC, hydrolysis a function of pH and biodegradation in surface waters[(a)].

Methods to be used with nano materials represent also an increasingly challenge.

Where tests on substances are required to generate information on intrinsic properties of substances they shall be conducted in accordance with the test methods laid down in a Commission Regulation or in accordance with other international test methods recognised by the Commission or the European Chemicals Agency. Some test methods useful to REACH are not yet implemented in the current legislation and will be published later. But the great majority will be transferred straightforwardly from the Annex V of the Directive 67/548/EC where the legally binding EU standardised methods according to which a substance can be classified as dangerous are indicated. In the Table I tests that may be needed for registration in REACH according to the tonnage associated to a manufacture or import are schematically indicated not regarding adaptation rules that may be applied.

Innovation pushed by the market threats and changes

It is expected that this Regulation will force a redraw of the market because of the withdrawl of substances no longer profitable particularly small volumes produced or imported.

TABLE I

TESTS FOR THE REGISTRATION OF SUBSTANCES AS REQUIRED BY THE REACH REGULATION

TONNAGE CLASS	PHYSICOCHEMICAL PROPERTIES
≥ 1 ton./yr	State of the substance state at 20ºC and 101,3 kPa
	Melting/Freezing point
	Boiling point
	Relative density
	Vapour pressure
	Surface tension
	Water solubility
	Partition coefficient n-octanol/water
	Flash-point
	Flammability
	Explosive properties
	Self-ignition temperature
	Oxidising properties
	Granulometry
≥ 100 ton./yr	Stability in organic solvents and identity of relevant degradation products
	Dissociation constante
	Viscosity
	TOXICOLOGICAL INFORMATION
≥ 1 ton./yr	Skin Irritation or skin corrosion : data assessment; acid or alkaline reserve assessment; tests *in vitro*
	Eye irritation
	Skin sensitisation
	Mutagenicity : *In vitro* gene mutation of bacteria
	Acute toxicity: by oral
≥ 10 ton./yr	Skin Irritation : *in vivo*
	Eye irritation : *in vivo*
	Mutagenicity: cytogenicity in mammalian cels *in vitro* or *in vitro* de micronucleus study
	Acute toxicity: by inhalation, by dermal route
	Repeated dose toxicity: short-term dose toxicity (28 days) one species, male and female
	Reproductive toxicity: screening for reproductive/developmental toxicity one species
	Toxicokinetics
≥ 100 ton./yr	Repeated dose toxicity: sub-chronic toxicity (90 days), one species, rodent, male and female
	Reproductive toxicity: pre-natal developmental toxicity, one species; Two-generation reproductive toxicity, one species, male and female
≥ 1000 ton./yr	Carcinogenecity study
	ECOTOXICOLOGICAL INFORMATION
≥ 1 ton./yr	Aquatic toxicity: short-term test on invertebrates (preferred on *Daphnia*)*;* growth inhibition of aquatic plants (algae preferred)
	Degradation: biotic, ready biodegradability
≥ 10 ton./yr	Aquatic toxicity: short-term test on fish; activated sludge respiration inhibition testing; Two-generation reproductive toxicity, one species, male and female
	Degradation: abiotic, hydrolysis as a function of pH
	Fate and behaviour in the environment: adsorption/desorption screening
≥ 100 ton./yr	Aquatic toxicity: Fish early-life stage (FELS); Short-term toxicity test on embryo and sac-fry stages; Juvenile growth test on fish
	Degradation: biotic, simulation on ultimate degardation on surface water; Soil simulation; Sediment simulation; Identification of degradation products
	Fate and behaviour in the environment: Bioaccumulation in aquatic species, preferably fish
	Effects on terrestrial organisms: short-term toxicity to invertebrates and plants; effects on soil micro-organisms
≥ 1000 ton./yr	Fate and behaviour in the environment: Long-term toxicity to sediment organisms; Long-term or reproductive toxicity to birds

But mainly substances of very high concern (SVHC[1]) will be put under a continuous pressure to withdraw the market as a consequence of an Authorisation process created in REACH with the purpose of ensuring a good functioning of the internal market while assuring that the risks from those substances are properly controlled. From another perspective this will be also a challenge to the research community help solving the problems raised by the disappearance or anticipated disappearance of substances from the market.

The substances identified as SVHC are first included in a list of substances that are candidates to be part od Annex XIV of REACH – the Annex that lists the substances that will need an authorisation to be used. According to a prioritisation criteria this list is ordinated and by that order the substances will be put in the work programme of the European Chemicals Agency (ECHA). The Agency will recommend then to the European Commission – the responsible for the final political decision - the inclusion of the substance in the Annex XIV of REACH. Once in this Annex manufacturers importers and downstream users will need to submit an application to the Agency whenever they want to use the substance.

The public in general and the scientific community may early alerted to the probability of a substance to became part of Annex XIV because of the publication of a notice on the website of the Agency that a dossier has been prepared for the identification of a substance as SVHC (Article 59(4)). Being positively identified as such the Agency there is another opportunity to spot the substance because of the obligation of the Agency to make a public consultation before sending the Comission a recommendation for the decision of inclusion. This consultation spans for three months after the date of publication and asks in particularly for the indication of uses that should be exempt from the authorisation requirement.

Once the substance included in the Annex XIV by the Commission the application for an auhorisation is clearly a burden on the use – besides the obligation for the applicant to pay a fee he needs to provide with the application and among other information a chemical safety report on the substance (unless already submitted as part of the registration), an analysis of the alternatives to the substance considering their risks and the technical and economic feasability of a substitution, including also, if appropriate, any relevant R&D activities by the applicant. If the analysis shows that there are suitable alternatives available the applicant will inform about a substitution plan for the substance and if appropriate information about any relevant R&D activities involved. And it should also be considered that authorisation will be subjected to time-limited reviews (Article 60(8)).

The substances on Annex XIV are then a problem for human health for environment and also for the enterprises who rely on them for their business.

So what is the advantage of the scientific community to early spot them as we previously pointed out? With the possibility to address a problem already identified as affecting the human health and the environment the scientific groups interested in those substances and its uses may start also to push their efforts to a solution and use themselves or through convenient partners the presentation of solutions to the substituition of the uses under authorisation , proposing either new substances or instead new technologies related with the uses and with its risk management measures. The presentation and arguing about the merits of the proposals will have an institutional european forum through the possiblity offered by the obligation of the Agency to make available information on its web-site whenever an authorisation is applied on its uses and receiving information on alternative substances or technologies submitted by third parties (Article 64(2)). This information will be analysed by the Committees for Risk Analysis and Socio-economic Analysis of the Agency who will draft an opinion on the application taking in consideration all the received information before a decision of the Commision on the granting of an authorisation, Summaries of the Commision

[1] Substances of very high concern in REACH are substances that are carcinogenic or mutagenic or toxic to the reproduction (CMR substances) or persistent, bioccumulative and toxic (PBT substances) or very persistent and very biaccumulative (vPvB substances). Others may raise equivalent concern – as for instance endocrin disruptors – and be subject of the same procedures under the regulation.

decisions including reasons for the decision, in particular when suitable alternatives exist, shall be published on the Official Journal of the European Union (Article 64(9)).

QSARS a research field of main importance to REACH

QSAR's (**Q**uantitative **S**tructure-**A**ctivity **R**elationship) are mathematical models useful to predict a particular endpoint based on the structural and chemical information of substances.

The use of QSAR's in the context of the REACH legislation becomes of great interest since it avoids the use of *in vivo* testing in vertebrates, and it also contributes to minimize the cost of gathering information for a specific chemical substance. Images like the ones seen on Draize's tests for eye irritation, where the substance to be tested is applied directly in the eye of a rabbit (or other mammallian) while it's reaction is visually monitored for large periods of time in which the animal is left suffering without any kind of relief of it's symptoms, are images that appeal to the development of new alternatives to this kind of testing.

Nevertheless the use of QSAR's should be applied bearing in mind the need to assure that it's capability of predicting a certain endpoint (avoiding vertebrate testing) is still compatible with the same level of protection of human and environmental health as before (Lilienblum *et al* 2008). This way, testing on vertebrates could be used only for substances that are predicted as non-irritant and non corrosive by the model, avoiding the use of *in vivo* testing for the ones already predicted as irritant or corrosive.

The OECD (**O**rganisation for **E**conomical **C**o-operation and Development) principles for QSAR validation (accepted for regulatory purposes under REACH legislation) stated that a QSAR should be associated with (Gramatica, 2007):

(P1) – a defined endpoint

(P2) –an unambiguous algorithm

(P3) – a defined domain of applicability

(P4) – appropriate measures of goodness-of-fit, robustness and predictivity

(P5) – a mechanistic interpretation (if possible).

The need for a defined endpoint it's in itself obvious since this is the prime goal of a QSAR. The last principle is limited by the knowledge one has about the mechanism and the way that a specific property or descriptor is responsible for the predicted endpoint. The concept of descriptor appears in QSAR's as an entity that exists in the system to be modulated (for example, the shape of the molecular orbitals, the molecular weight or the acidity of the molecule) and can be associated with a certain endpoint (for example, acidity it's related to skin corrosion).

A brief review concerning (P2), (P3) and (P4) is made outlining some important guidelines on QSAR use under the scope of REACH legislation (Annex XI).

The unambiguous algorithm that (P2) refers to, should also be able to accurately predict a certain endpoint for any chemical substance that falls within the domain of applicability. Included in the algorithm is not only the mathematical method of calculation, but also the specific molecular descriptors required in the model. Almost all the developed QSAR's use certain physicochemical properties as molecular descriptors for the model.

Benfenati *et al.* (2003) pointed out that commonly used molecular descriptors, may be calculated or experimentally determined mixing different methodologies with a strong effect on the output of the QSAR in use. For example, the use of a QSAR model based on *log* K_{OW} (logarithm of the octanol/water partition coefficient) as the molecular descriptor for nonpolar narcosis in fish, expressed as:

$$\log (LC_{50}) = -0{,}846 \log K_{OW} - 1{,}39$$

can't be used to give a reliable prediction unless care is taken to ensure that *log* K_{OW} is obtained using the same methodology than the one used in obtaining this correlation. Although *log* K_{OW} is well defined by thermodynamics, and this descriptor is well known,

several methodologies are accepted to it's determination, resulting in different values.

The domain of applicability referenced in (P3) is a theoretical region in chemical space, defined by the model descriptors and modeled response obtained during the use of the training set.

It's important to note that even a validated QSAR can't be expected to give a good prediction if any chemical substance that doesn't fall within it's domain of applicability is tested. Care should be taken on which substances to include in the training set and in the test set (Eriksson *et al.* 2003).

The goodness-of-fit, robustness and predictivity of the model are included in (P4). The R^2 (R^2 = (1- RSS/TSS), where RSS is the Residual Sum of Squares and TSS is the Total Sum of Squares] is the most widely used measure of the goodness-of-fit of a QSAR, and usually no attention is taken upon robustness (insensibility of the model to the uncertainties in the experimental measures) and predictivity.

The most commonly used approach to assess model predictivity is cross validation in which, statistical techniques are applied to evaluate the effect of iteratively removing different proportions of the training set (Q^2_{LOO} known as Leave One Out approach). A detailed discussion upon these parameters can be found in Gramatica (2007).

As an example of the possible usage of QSAR's under the REACH scope is the capability they provide for predicting eye and skin irritation/corrosion (needed for substances which are produced in a range of 1 to 10 ton/year, as seen in Table 1).

The mechanisms for skin and eye irritation are diverse and not fully understood. Some of the parameters accepted as influencing this kind of phenomena are: the acid or basic properties of the substance, its capability of penetrating the skin (function of hydrophobicity and molecular size) and cytotoxicity.

The use of QSARs in this field of application is in the origin of some good expert systems for assessing irritation and corrosion (some of them available as an application software corresponding to the gathering of several QSARs and their descriptors). Several reviews can be found in literature, comparing each software and its functionality. Examples of this software are:

DEREK (for windows) – Deductive Estimation of Risk from Existing Knowledge[(b)]

MultiCASE – Multiple Computer Automated Structure Evaluation[(c)]

TOPKAT – Toxicity Prediction by Komputer-Assisted Technology[(d)]

An extended review on the use of QSARs to predict eye and skin irritation/corrosion is available in Saliner *et al.* (2008).

Although there is a great amount of published QSARs and studies developed for several endpoints, the applicability of each one for the purpose of REACH regulation should be made under the OECD principles of validation for QSARs and each case should be treated with precaution. For some of these studies difficulties are expected in its use for regulatory purposes, but this should be interpreted as an incentive for further development in this particular area of knowledge.

The development of global databases searchable and accessible by any parameter of interest (endpoint, applicability domain, etc) is a future demand, and efforts are already being made for this goal.

Simulation optimizes feedback control on the temperature of a heterogeneous batch reactor

M. Çetin Koçak *
Chemical Engineering Department, Engineering Faculty, Ankara University, Tandoğan 06100, Ankara, Turkey

Keywords: Dynamic simulation, Feedback control, Heterogeneous batch reactor, MATLAB, SIMULINK
Topic: Systematic methods and tools for managing the complexity

Abstract

This work is a SIMULINK® application using its non-linear S-function block to solve a feedback control problem posed by Franks (1972). The controller's task is to raise the temperature of a heterogenous batch reactor to a certain level as rapidly as possible, with minimum overshoot, and maintain it there for the remainder of the reaction. The research required a thorough study of DYFLO (Franks, 1972), development of a mini package in MATLAB® environment, model adaptation with suitable modification, open-loop verification by comparison with the original, construction of a SIMULINK® diagram including a single S-function block housing both the reactor and the newly added temperature control loop, open-loop verification again, and finally closed-loop experimentation with controller settings.

1 Introduction

Many dynamic models can be compactly represented in vector form by a set of algebraic equations $\underline{0} = \underline{g}(t, \underline{x}, \underline{a}, \underline{c})$ coupled to a set of differential equations $\underline{x}' = \underline{f}(t, \underline{x}, \underline{a}, \underline{c})$ where t, $\underline{x}$, $\underline{a}$, and $\underline{c}$ respectively denote the independent variable time, state variables, algebraic variables, and constants. Further, the prime $(')$ indicates differentiation with respect to t.

Simulation almost always means a series of small steps of numerical integration because analytical solution is either unavailable or intractable. Design and optimization may require several simulation runs starting from $t = 0$ and advancing to a pre-specified time or state, producing output at regular intervals. Boundary conditions and/or some constants may vary from one run to the next.

Simulators usually offer a set of different driver routines each one handling the chores of a particular numerical integration method. Triggered after appropriate data initialization, these solvers can supervise a run calling upon the nominated model function as often as necessary. They expect this function to solve $\underline{0} = \underline{g}(t, \underline{x}, \underline{a}, \underline{c})$ for $\underline{a}$ at the current time and state prior to calculating and returning fresh derivatives. Figure 1 shows a typical simulation run.

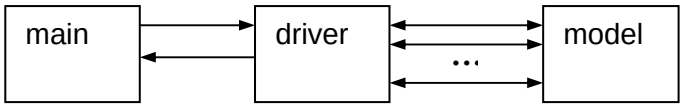

Figure 1. Typical simulation run.

Simulators may be classified as equation-oriented or modular. When the model partly or wholely partitions the algebraic and differential equation sets between sequential modules as in the famous DYFLO (Franks, 1972) care must be taken to preserve simultaneity. ACES

* Tel + 90 312 212 67 20 Ext.1330. E-mail:kocak@eng.ankara.edu.tr

(Koçak, 1980) pioneered true simultaneous modularization by twice-round execution of modules. DYFLO and ACES are both Fortran-based, modular chemical engineering simulators without a preprocessor.

MATLAB® is a highly convenient simulation environment with many integrators, e.g. ode23, ode45, and ode15s functions. The latter is a driver for stiff models. SIMULINK® is far useful than the standard MATLAB® package for control system simulation. SIMULINK® enables the rapid construction and simulation of control block diagrams (Bequette, 2003). Its library offers many linear and nonlinear blocks as icons which can be dragged and dropped into a model workspace. Block parameters and coefficients may be entered here by double-clicking on the icon. Its easy to connect the blocks by arrows. Standart input functions such as step and ramp are supplied. The simulation parameters can be changed by going to the Simulation pull-down menu and modifying the stop time or the integration solver method.

The S-function icon is in the nonlinear library of SIMULINK®. When simulations are performed, the equations in the m-file named by the S-function block are claimed to be solved simultaneously with other blocks in the diagram.

2 The Model

The heterogenous batch reactor whose temperature is to be controlled has three phases, where several phenomena occur simultaneously, making manual calculations virtually intractable. An organic compund A is hydrogenated to compound C via an intermediate B, i.e. $A + H_2 \rightarrow B,\ B + H_2 \rightarrow C$. This reaction occurs on the surface of a metal catalyst in the form of loose particles, the reagents diffusing from the liquid phase to the catalyst surface, reacting and returning to the liquid phase. A degree of control over the internal temperature can be achieved by a series of cooling coils contacting the liquid phase. The reaction is highly exothermic, which will cause a significant rise in the temperature and pressure during the course of the reaction, monitored by suitable instrumentation. A significant exchange of material between the liquid and vapor phases occurs as the reaction proceeds with the simultaneous division of heat energy. However, all phases will have the same temperature since the agitation has sufficient violence to maintain equilibrium.

For this reactor, Franks (1972) developed a dynamic model with five components by writing mole and heat balances considering the reaction system as a whole. As depicted in Figure 2, a flash calculation involving trial-and-error established the vapour-liquid split as well as the equilibrium temperature and pressure. Ideal behaviour is assumed throughout.

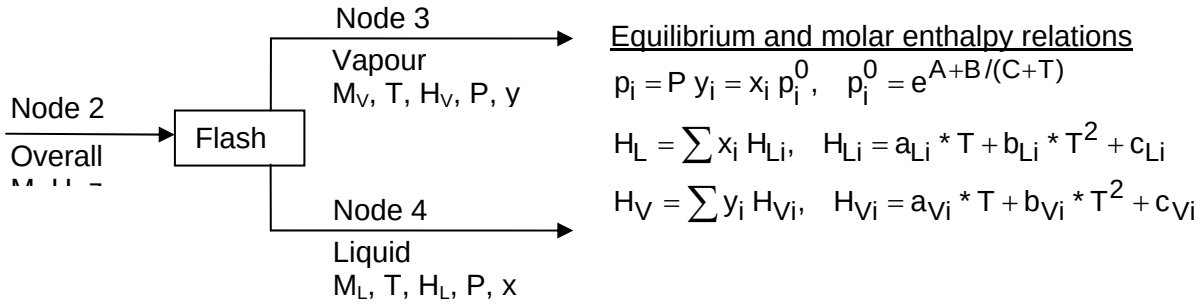

Figure 2. Flash calculation.

For lack of space, description of the model will be brief. The reaction system loses heat to the vessel and the coils at the rates Q_W and Q_C respectively:

$$Q_W = UA_W\,(T - T_W),\quad Q_C = UA_C\,(T - T_C),\quad HT = Q_W + Q_C \tag{1}$$

The subscripts G and S respectively denote the hydrogen gas and the solvent. Suppose W is the catalyst weight. Let

$$R_1 = \frac{k_1 x_A W}{den}, \quad R_2 = \frac{k_5 W^2 x_B x_G}{den^2}, \quad den = 1 + K_4 x_B + K_2 x_G + K_6 x_C \tag{2}$$

The dynamic mole balances are as follows:

$$\frac{dM_A}{dt} = -R_1, \quad \frac{dM_B}{dt} = R_1 - R_2, \frac{dM_C}{dt} = R_2, \frac{dM_G}{dt} = -R_1 - R_2, \frac{dM_S}{dt} = 0, \quad \frac{dM}{dt} = -R_1 - R_2 . \tag{3}$$

The accompanying heat balances are

$$\frac{d(M\ H)}{dt} = R_1(-\Delta H_1) + R_2(-\Delta H_2) - HT , \tag{4}$$

$$\frac{dT_W}{dt} = \frac{Q_W}{MC} . \tag{5}$$

Consider the control loop now. The reactor temperature is measured with a thermal system having a first-order time constant of 0.4 minutes, so

$$\frac{dT_M}{dt} = (K_M * T - T_M)/\tau_M, \quad K_M = 1, \quad \tau_M = 0.4 . \tag{6}$$

The temperature of the coolant through the coils is obtained by mixing two fluids with temperatures of 130º C and 70º C. The mixing is assumed to be linear with valve position X_v. The valve response to the control signal CO can be simulated with a first-order time constant of 0.05 minutes. Thus,

$$\frac{dX_V}{dt} = (K_V * CO - X_V)/\tau_V, \quad K_V = 1, \quad \tau_V = 0.05 , \tag{7}$$

$$T_C = 70 + X_V * (130 - 70) \tag{8}$$

The task of the controller is to raise the reactor temperature to $T_{SET} = 120^{\circ}$ C as rapidly as possible, with minimum overshoot, and maintain it at this level for the remainder of the reaction. Let

$$ERR = T_{SET} - T_M \tag{9}$$

The output of a P type controller is

$$CO = CO_0 + K_C * ERR \tag{10}$$

If

$$ERRINT = \int ERR\, dt , \tag{11}$$

then the output of a PI type controller are

$$CO = CO_0 + K_C * (ERRINT/\tau_I + ERR) . \tag{12}$$

The simulation part of this work is organised as follows:

1) The file “hb_sfun0.m” is triggered from the command window of MATLAB®.

2) After some preliminaries, this file calls SIMULINK® driver function “sim” which activates “hb_sfun_sim.mdl” shown in Figure 3. Easily constructed, this diagram simply indicates that the S-function block is asscociated with the “hb_sfun.m” file and outputs M, T, H, and P values. (These pertain to the liquid phase.)

3) SIMULINK® sets a flag to 0, 1 or 3 to signal that dynamic blocks in “hb_sfun_sim.mdl” should enter their own initialization, derivative calculation or output sections respectively.

4) When the run is over, “sim” returns the time and state profiles to the place it was triggered. The output profiles are made available in the workspace. Note that SIMULINK® window allows the user to select the integration driver and specify the run interval as well as output times.

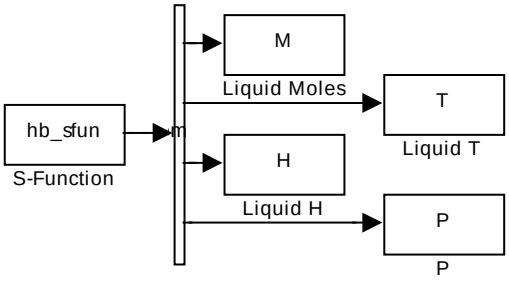

Figure 3. SIMULINK® diagram with an S-Function block.

Now, the only dynamic block in this set up is an S-function associated with the “hb_sfun.m” file given in Figure 4. (Note: Any workspace containing a global statement has permission to read and modify the objects it names. This statement helps shorten argument lists.) The X argument denotes the state vector here. Notice that state variables are in fact plant values forwarded as X0 on the first entry ($flag = 0$) and back-transferred on each subsequent call. The DX vector holds the state derivatives. The model with a PI controller has a total of 11 state variables in the order zz(2,1), zz(2,2), zz(2,3), zz(2,4), zz(2,5), HHOLDM(2), eenmpm(2), TW=TT(5), TM=TT(7), XV, and ERRINT. (For open-loop study, the last three derivatives (DX(9), DX(10), and DX(11)) are reset to zero.)

      sys=[HHOLDM(4) TT(4) eenpm(4) PP];
   case {2,4,9}
      sys=[ ];
end
```

Figure 4. The hb_sfun.m file.

When $\text{flag} = 1$ the entry is for DX values. The call to the PPflash function establishes the vapour-liquid split. Equations (1) through 2 to (4) are complete on exit from the bbatch function. Equation (5) corresponds to DX(NC+3)=FFE(1)/MCP. Equations (9) and (12) are easily recognised. As indicated in the listing, the changed from PI to P type is achieved simply by tailoring (12) to (10). Equations (6), (7) and (11) appear on the line containg (12). Finally, in order to obtain an open-loop response, just activate the statement $DX(9:11) = 0$ by removing the leading % sign. When $\text{flag} = 3$ the entry is for output estimation. This short section needs no explanation.

Activated from the command window, the script file "hb_sfun0.m" attends to pre-initialisation tasks like filling pysical property database, giving the reactor's first charge, and specifying controller parameters to be tested before calling the SIMULINK® driver (sim function) and passing over the name "hb_sfun.m" as the model file. As seen in Figure 5, the call to sim function returns tt and XX as the collected values of time and state respectively.

```

Figure 5. The hb_sfun0.m file.

Table 1 compares the open-loop response of the reactor with the original (Franks, 1972). The harmony is reasonable considering the changes of organisation, integration driver, iteration techniques, and accuracy criteria.

Table 1. Open-loop response of the batch reactor.

	$t = 0$ min		$t = 10$ min	
Liquid Phase	This work	Franks, 1972	This work	Franks, 1972
M (moles)	23.9192	23.92	12.2237	12.19
T (º C)	77.4336	77.43	153.274	153.6
H (PCU)	2579.9	2580	6020.0	6034
P (atm)	7.5574	7.557	18.5488	18.76
x_1	0.1840	0.1840	0.0068	0.0073
x_2	0.0000	0.0000	0.0486	0.0503
x_3	0.0000	0.0000	0.1806	0.1776
x_4	0.4045	0.4045	0.1099	0.1116
x_5	0.4115	0.4115	0.6540	0.6532

Many PI settings were tested but only two results were selected for display in Figure 6 together with the open-loop response. Both seem satisfactory considering the assignment. Possibilities for future work include formal optimization of controller settings, segregation of the model into several S-function blocks without spoiling simultaneity, and combination with built-in linear elements of SIMULINK®.

P.O. Box 676, Post Code 13565-905, São Carlos, SP, Brazil.

Keywords: Taylor vortex flow, mass transfer, volumetric oxygen transfer coefficient (K_La), animal cell culture, bioreactor.
Topic: Integration of life sciences and engineering.

Abstract

In biochemical processes involving cultivation of animal cells, the supply of oxygen in culture medium is an extremely important parameter in the project of bioreactors and its operation. An inadequate transfer of oxygen can lead to rapid changes in cell physiology, metabolism, productivity, product quality and cell death. In this work, the global volumetric transfer coefficient of oxygen (K_La) is evaluated in a Taylor vortex flow bioreactor (TVFB) and a correlation of mass transfer, of this equipment, is proposed. The experimental conditions employed in TVFB were: rotational Reynolds number between 244 and 2928, airflow rates varying from 80 mL.min^{-1} to 550 mL.min^{-1} and used culture medium DMEM in liquid phase. The results of this study suggest that Taylor-vortex flow regimes provide an effective oxygen transport required for long-term cell culture.

1 Introduction

In the last 20 years, there have been rapid increase and progress in the development and use of large-scale animal cell cultivations for the commercial production of therapeutic and diagnostic biochemicals, as viral vaccines, monoclonal antibodies and recombinants proteins (Ma et al., 2002). Nowadays, for commercial production, cells are often cultured in large scale stirred bioreactors. Within of that equipment, the fluid dynamic environment may be used to enhance delivery of oxygen and other chemical species (as nutrients) to cells through forced convective transport (Curran and Black, 2005). The supply of oxygen to production cultures during scale-up is an important part of bioprocess design (Butler, 2004). At high cell densities ($>10^6$ cells.mL^{-1}) or at high volume cultures ($>$10L) gas diffusion in this kind of bioreactor is not adequate to meet the metabolic demands of the cells (Konz et al., 1998). A constant oxygen supply is required because of its low solubility in water (7.8 mg.L^{-1} at 25°C), and even lower in culture media, depending on the composition. Nevertheless, the conventional methods of agitation and aeration generally used in microbial culture bioreactors are difficult to apply due to the physiological characteristics of animal cells. The absence of cell walls in mammalian cells and their relatively large size make them particularly sensitive to shear forces. The cell damage caused by bubble bursting were performed by Hand-Corrigan et al. (1989), Kunas and Papoutsakis (1990), Chalmers and Bavarian (1991), Wu (1995), Camacho et al. (2000), among others.

As it can be observed in the literature, the oxygen transfer is a limiting factor on the bioreactor design. Therefore, the main objective of this work is to assess the potential use of a Taylor vortex flow bioreactor (TVFB) designed and built at the Department of Chemical Engineering of São Carlos Federal University, for cultivation of animal cells. The overall volumetric oxygen mass transfer coefficient (K_La) and mass transfer correlation was estimated under Taylor vortex flow regimes. TVFB has a non-conventional configuration, when compared to other bioreactors like stirred tank and airlift, it consists of two concentric

cylinders, one internal rotating cylinder and the other external stationary. Taylor vortices are secondary flow patterns that appear above a critical rotation, determined by the critical Taylor number, in the gap between inner (rotating) and outer (rotating or stationary) cylinder (Taylor, 1923). The vortex is capable of fulfilling the gap between the two cylinders in a stable and reproductive way that provides an efficient mixture of the medium, ensuring favorable conditions of pH, temperature, nutrients and a less aggressive agitation of the medium for the cells inside the bioreactor (Moore, 1994, Giordano et al., 1998, 2000a and b; Resende, 2002). Taylor vortex flow is more appropriate in cell cultures involving shear sensitiveness, as animal cells, because the transition from the previous flow, known as Couette, for Taylor produces the reduction in shear, as an overall effect. The decrease of shear stress (tangential) is due to decomposition by the vortex of tension applied by internal cylinder in three components: axial, radial and tangential. When working with anchorage dependent animal cells, in a heterogeneous system, the rotation of the inner cylinder is an additional operating variable that may facilitate particle fluidization. In order to reduce hydrodynamic shear damage in the cell culture due to bubble breakup, a silicone tubular membrane around all inner cylinder was used. This system allows the diffusion of gases in the culture medium, through the membrane, without the formation of air bubbles.

2 Materials and methods

2.1 Equipment

The experiments were performed in a Taylor vortex bioreactor with a useful volume of 800mL. The photograph of TVFB is illustrated in Figure 1. The TVFB is composed of two concentric cylinders, where the internal one is rotating and manufactured in polypropylene, while the external is stationary and is manufactured in glass and stainless steel. The outer cylinder has a heat exchanger which is responsible for maintaining the temperature inside the equipment in the desired value using a water closed loop allied to an external water heater. The electrodes used to monitor and control the pH, dissolved oxygen and temperature are introduced by appropriate holes in the base of the outer cylinder. Aeration of the culture medium was achieved by a silicone tubular membrane, which has an outer diameter of 4.4 mm and a wall thickness of 0.55 mm.

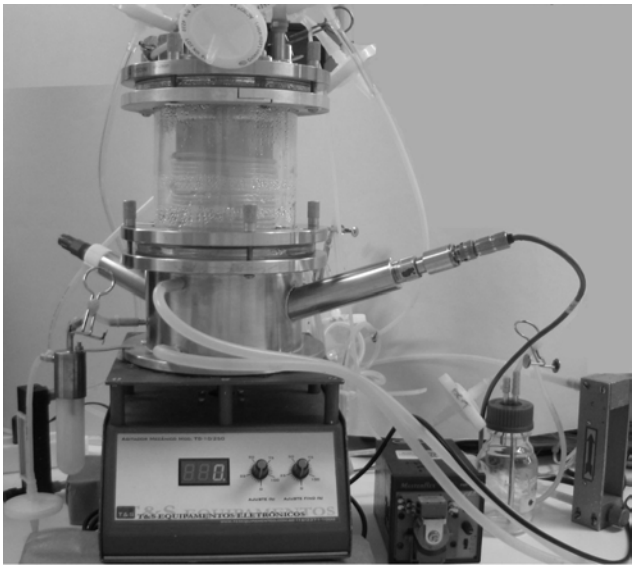

Figure 1: Photograph of the Taylor vortex flow bioreactor (TVFB) used in the experiments.

2.2 Measurement of the overall volumetric oxygen transfer coefficient (K_La)

The measurement of the overall volumetric oxygen mass transfer coefficient (K_La) is based on the dynamic gassing-out method using an oxygen electrode. Equation 1 is used for evaluation of K_La.

$$\frac{dC}{dt} = K_L a(C^*_{O_2} - C_{O_2}) \tag{1}$$

where, $K_L a$ is the overall volumetric oxygen mass transfer coefficient, and a is interfacial area of the mass transfer per unit volume, in this case the area is the surface of the tubular silicone membrane; C_{O_2} is the oxygen concentration in the medium (mmol.L^{-1}), $C^*_{O_2}$ is the oxygen concentration in the medium in equilibrium with air (mmol.L^{-1}) (Blanch and Clark, 1997).

The method consists in provoking abrupt changes of dissolved oxygen concentration between two known steady states. It is possible by gassing it with nitrogen within the bioreactor, eliminating all dissolved oxygen. After the elimination of oxygen inside the bioreactor, the aeration is turned on at the conditions desired for that experiment (agitation and air flow rate), which is equivalent to the application of a step function of aeration in the system. The experiments were carried out in the TVFB of 1L (0.8L working volume), operated in the absence of cells, at 37°C, containing culture medium DMEM ($Dulbeco's Modified Eagle's Medium$ - Cultilab). The experimental conditions were: inner cylinder rotation rate varying from 25 to 300 rpm with aeration varying from 80 mL.min^{-1} to 550 mL.min^{-1}. The dissolved oxygen concentration was measured by a sterilizable electrode (Mettler-Toledo, model INPRO 6100/120/S/N) bearing a Teflon membrane (Mettler Toledo, model InPro T-96). The data acquisition, control equipment and sensor transmitters are manufactured by Autsens Industry, model SIMAD. All data was collected from the process, stored in its internal memory and, after the experiment, transferred to personal computer by a RS232 interface.

2.3 Mass transfer correlation of TVFB

Mass transfer is one of the most intensively investigated aspects of Taylor vortex flow. Mass transfer characterization typically employed dimensional analysis to correlates a mass transfer parameter (Sherwood number) to experimental data. Sherwood number which represents the ratio of actual convective mass transfer to purely diffusive transfer, is given by (2).

$$Sh = \frac{k_L \cdot d}{D} \tag{2}$$

where d corresponds gap between concentric cylinders; D is the oxygen diffusion coefficient in the liquid phase and k_L that corresponds mass transfer coefficient of liquid film.

In order to evaluate Sh, the mass transfer coefficients must be determined for each experimental vortex flow regime. In this study, other non-dimensional parameters were selected, as the rotational Reynolds number defined by (3) which corresponds to the ratio of viscous to centrifugal forces.

$$R_{e\theta} = \frac{\omega r_{in} d}{\nu} \tag{3}$$

where ω is the velocity of inner cylinder rotation, d corresponds the gap width between the cylinders, r_{in} is the inner radius and ν is the kinematic viscosity of fluid medium, in this case culture medium DMEM, at 37°C.

The air Reynolds number ($R_{e_{air}}$), defined by (4), which represents the ratio between the air rate flow and the product of membrane diameter by air viscosity. This dimensionless number equation was deduced exclusively for this work.

$$R_{e_{air}} = \frac{4}{\pi} \frac{Q}{d_{in} \nu_{air}} \tag{4}$$

where Q is the entry of airflow in equipment, d_{in} is the inner diameter of silicone tubular membrane and ν_{air} is the kinematic viscosity of air at 37°C.

So, the mass transfer correlation takes the following general form:

$$Sh = aR_{e\theta}^{b}R_{e_{air}}^{c} \tag{5}$$

where a, b and c are constants (Santiago, 2007).

3 Results and Discussion

Figure 2 illustrates the values of K_La in TVBF according to the rotational Reynolds number ($R_{e\theta}$) for each airflow rate that flows by the tubular silicone membrane (80 to 550mL.min^{-1}).

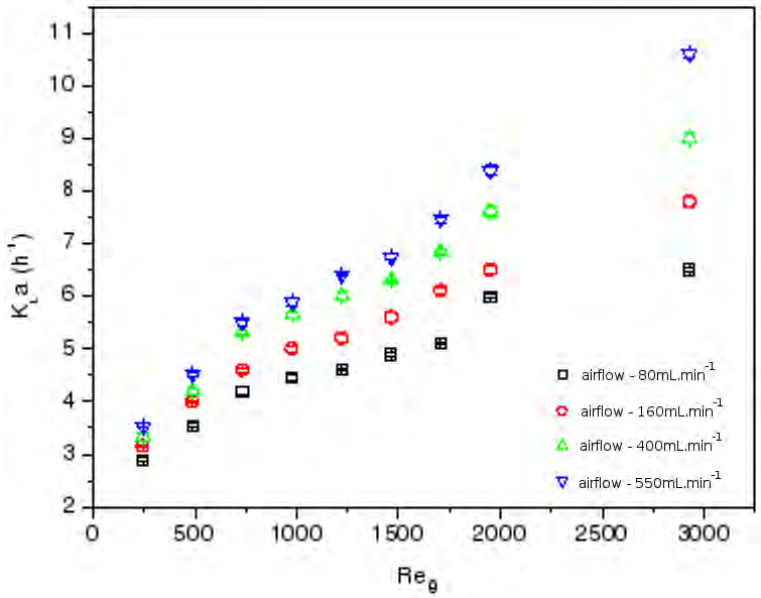

Figure 2: Experimental values of K_La as a function of rotational Reynolds number ($R_{e\theta}$) on TVFB. The experiments were made in cell-free media, at 37°C, containing culture medium DMEM and different airflow rates. The error bars correspond to the standard deviation of experiments performed in triplicates.

The results of K_La in the TVFB ranged from 3.0 to 10.7h^{-1}, which can be considered high when compared to other conventional rotating wall and other kinds of bioreactors used for animal cell culture, as the stirred tank. In this graph, the increase of Reynolds dimensionless number ($R_{e\theta}$) and the airflow rate contributed to a greater oxygen transfer to the liquid medium. Curran and Black (2005) performed experiments to determine K_La in Taylor vortex flow bioreactors, called DC-25R and using aeration in the surface, where the obtained results were: 0.6h^{-1} for $R_{e\theta}$=203 and 0.78h^{-1} to $R_{e\theta}$=1018. Values considered small because it is difficult to increase the scale of equipment.

In experiments performed in agitated tank bioreactors, employing tubular silicone membrane for aeration of the culture medium, values obtained from K_La were: 2 to 3h^{-1} (Tonso, 2000, Qi et al., 2003). In these works, the lengths of membranes ranged between 50 and 80 meters and its dimensions were similar to those used in membrane TVFB. Comparing the results of K_La in TVBF, operated under conditions similar to this bioreactors, it can be noted that the equipment enables an efficient oxygen transfer and mixture of medium, with a smaller length of the membrane, only 7m.

3.1 Mass Transport Correlation

In the experimental range of the used parameters, $R_{e\theta}$ between 244 and 2928 and airflow rates varying from 80 mL.min^{-1} to 550 mL.min^{-1} ($37 < R_{e_{air}} < 254$), the overall volumetric oxygen mass transfer

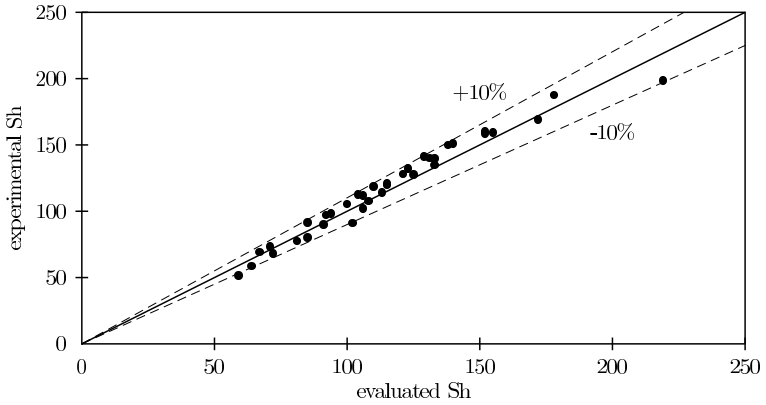

Figure 3: Comparison between calculated (Eq. 6) and experimental data of the Sh.

coefficient (K_La) varied from 3.0 to 10.7 h^{-1}. This leads to the mass transfer correlation of TVFB shown in Equation 6.

$$Sh = 2.97 R_{e\theta}^{0.4} R_{e_{air}}^{0.18} \tag{6}$$

The values of the parameters were obtained considering a confidence interval of 95%, and a correlation coefficient value (R^2) of 0.96, which ensures that the proposed model adequately describes the experimental data. The exponent of $R_{e\theta}$ (a) is around 0.5, since this value corresponds to the majority of correlations found in the literature for the case of Taylor vortex flow bioreactors with narrow gap ratios ($b/r_{in} < 0.5$) and small or zero axial flow (Moore, 1994).

Figure 3 shows a comparison between the experimental values of Sh and the values calculated for Sh by equation 6. It can be observed the difference between the experimental and calculated values of Sh are lower than 10%. As expected, the effects of increasing $R_{e\theta}$ and $R_{e_{air}}$ on K_La are positive, as shown by the exponent signals.

4 Conclusions

These results suggest that the TVFB has been identified as a competitive solution for animal cell culture in bioreactors, once it provides an effective means for oxygen transport. Membrane-aeration offers a convenient means of supplying oxygen to mammalian cell bioreactors with minimal introduction of shear, because it avoids the disruption of air bubbles in the gas-liquid interface. The mathematical model presented in this study allows estimation of the mass transfer in TVFB, considering the overall volumetric oxygen transfer coefficient (K_La), the operating conditions and the geometry of the bioreactor.

Abstract

Amino acids are well metabolized during the clavulanic acid, CA, production process by *Streptomyces clavuligerus* cultivation with glycerol as carbon and energy source. However only some amino acids, such as arginine and ornithine, are favorable to CA biosynthesis. The aim of this work was to optimize the glycerol:ornithine molar ratio in the feed medium to enhance CA production in continuous cultivation. Factorial design experiments showed that a glycerol: ornithine molar ratio of 40:1, in the feed medium, resulted in the the highest CA concentration. Fermentor runs, under the optimized conditions, resulted in CA concentration enhancement above twice the value observed during the factorial design experiments with shake flasks.

1 Introduction

Clavulanic acid (CA) is commercially produced by *Streptomyces clavuligerus* in rich media containing glycerol as the main C and energy source, and complex nitrogen sources, such as soybean flour or soybean cake, that yield high CA production. These complex nitrogen sources, however, usually contain also undesirable components that interfere with microbial metabolism. In this way, amino acids and soluble components such as protein extracts and hydrolizates produce broths less viscous and more homogeneous, enhancing mass and heat transfer, facilitating monitoring and control of process variables, as well as it can make simpler the separation and purification steps (Elander, 2003). Despite that the great majority of amino acids are well metabolized by the microorganism, only some of them are favorable to CA biosynthesis. Such is the case of arginine and ornithine, precursors of CA molecule (Romero et al, 1984). However, Romero et al. (1984, 1986) observed that supplementary arginine in the medium may lead to intracellular accumulation of glutamate that, according to these authors, affects negativelly the production of CA. Ives and Bushell (1997) fed a continuous culture with single amino acids belonging to the main carbon flux of the biosynthetic pathway of CA; they observed that the addition of leucine, isoleucine, serine or valine, but not arginine, led to production rate increase. In another recent work, Bushell et al. (2006) evaluated the carbon fluxes working with media limited by phosphate, nitrogen or carbon utilizing Metabolic Flux Analysis techniques. These authors observed no significant correlations between reactions which fluxes are linked directly to arginine. This fact is in agreement with the work of Kirk et al (2000), suggesting that the biosynthesis of this amino acid is saturated in CA production process under phosphate-limited conditions. Chen et al.

* Corresponding author. Tel + 55-16-33016710. E-mail:mlaraujo@iq.unesp.br

(2003) observed that feeding ornithine in fed-batch culture not only provided an adequate supply of arginine for CA production, but also inhibited the glycerol-utilizing cephamycin biosynthesis. These results made clear that ornithine, rather than arginine, enhances effectively CA production if the amount of C3 precursor (glycerol) is sufficient. Thus, the aim of this work was to optimize the molar ratio between glycerol and ornithine in the feed medium making use of Factorial Experimental Design (Box et al, 1978) in order to achieve higher CA concentration.

2 Materials and Methods

Streptomyces clavuligerus ATCC 27064 used throughout this work was stored in the form of vegetative cells (8.0 $g.L^{-1}$ dry weight) at −70°C in cryotubes, utilizing glycerol 20% (w/v). Inoculum medium was composed of (in g/L) glycerol (15.0), soybean protein isolate (Soytone) (15.5), yeast extract (1.0), Malt extract (10.0), K_2HPO_4 (0.8), $MgSO_4.7H_2O$ (0.75), 1.0 mL/L of salt solution containing: (in g/L) $MnCl_2.4H_2O$ (1.0), $FeSO_4.7H_2O$ (1.0) e $ZnSO_4.7H_2O$ (1.0). Production medium had the same composition except that malt extract was not added. The media were supplied with 21 g/L of MOPS, and initial pH was adjusted to 6.8.

Fermentation was carried out in shake flasks (250 rpm, 28ºC) and in bench scale fermentor (News Brunswick Bioflo 2000, 5L working volume), experiments were carried out with automatic control of pH (6.8±0.2), temperature (28 ºC) and DO level (approximately 40% saturation by varying agitation speed), 1 vvm aeration rate. In both casesm shake flasks and fermentor, after 48 h cultivation, broth withdrawal and medium feeding were accomplished at $D = 0.005\ h^{-1}$. The feed medium was composed of tap water 5%, MOPS (21 g/L) and several combination of glycerol and ornithyne concentrations. Same medium and dilution rate were utilized for a 5 L bioreactor run (DO controlled above 40% saturation). CA was determined by the method described by Bird et al. (1982), cell mass was determined as dry weight and glycerol by the method described by Lambert and Neish (1950).

Concentration range for the independent variables – glycerol (x_1) and ornithyne (x_2) – were defined based on the literature, setting the response variable as CA concentration (mg/L), at 144 h cultivation. Romero *et al.* (1986) observed that glycerol concentration of 165 mM inhibited CA synthesis while ornithine (ca. 5 mM) exerted a positive effect. A central composite factorial design was performed, with x_1 e x_2 from –1 to +1 (coded units), and added star (x_1 e x_2 from $-\sqrt{2}$ to $+\sqrt{2}$) (Box et al., 1978).

3 Results and Discussion

In all experiments biomass concentration was assumed constant, around 8 g/L, and the residual glycerol concentration was practically zero despite its addition through the feed medium (Figure 1).

Statistical analysis resulted in a response surface adjusted at 95% confidence level and 0.91, determination coefficient. The resulting response surface, fitted by Equation 1 (x_1 and x_2 in coded units) with the significant parameters, predicted maximum CA concentration (mg/L) at a molar ratio glycerol to ornithyne of 40, corresponding to 87 mM and 2.12 mM, respectively, in the flask at the moment of each addition (Figure 2). The statistical evaluation of data indicated that CA production decreases whenever there is any minor change in glycerol or ornithine concentration around the values of the optimized ratio.

$$C_{AC} = 472.4\ (\pm 18.0) - 20.8\ (\pm 12.8)\cdot x_1 - 68.6\ (\pm 14.4)\cdot x_1^2 - 89.2\ (\pm 14.2)\cdot x_2^2 \qquad \text{(Eq. 1)}$$

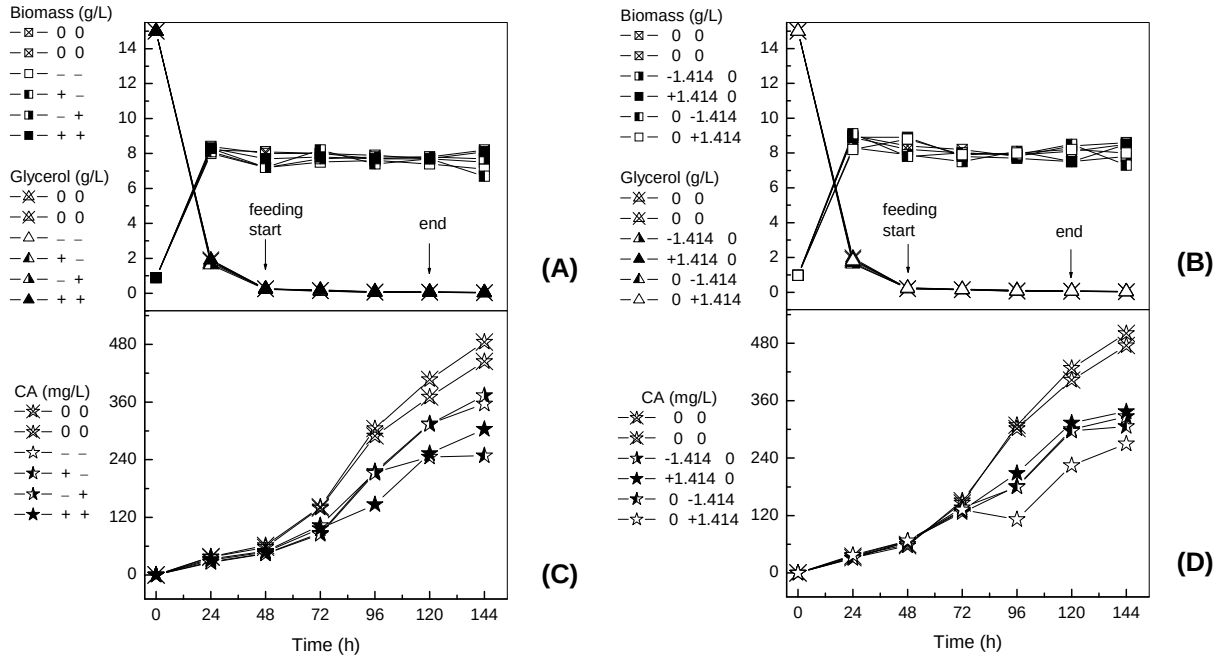

Figure 1 – Central composite factorial design with added star – time course of biomass and glycerol (A and B), and CA (C and D)

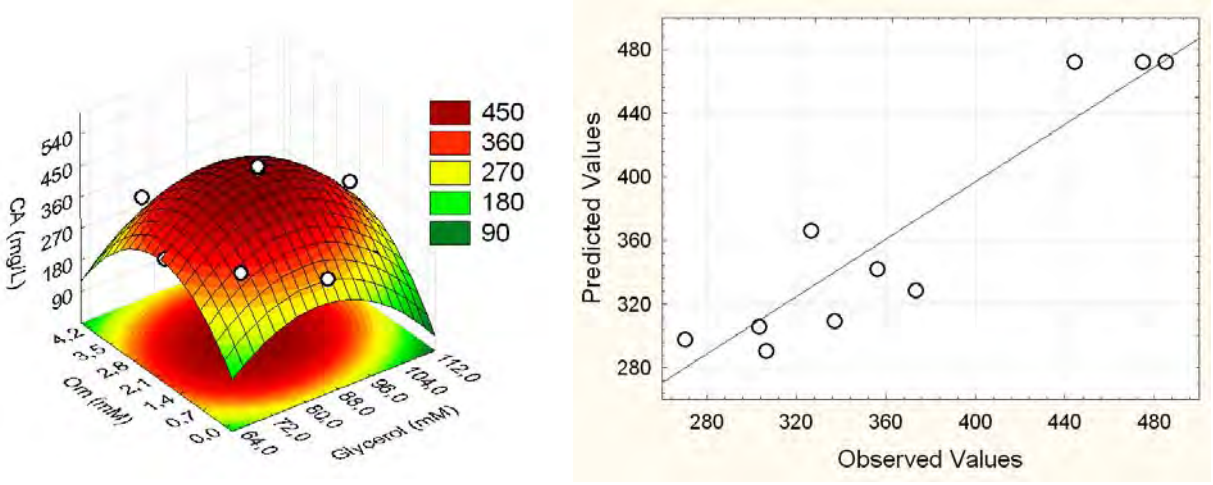

Figure 2 – Fitted response surface (0.91 determination coefficient at 95% confidence level) (A) and observed vs. predicted values of CA (mg/L) obtained at 144 h of continuous process in shake flasks (D = 0.005 h^{-1}) (B)

The optimized molar ratio was tested in a feed medium containing 70.7 mM glycerol and 1.72 mM ornithine. These concentrations are ca. 20% lower than that utilized originally (Figure 3). Under these conditions, CA production has stabilized at levels 25% greater than previously, after 72 h. The optimized molar ratio was then utilized in a experiment with a 5 L bioreactor provided with agitation and aeration, at the same dilution rate as that utilized in shake flasks, D = 0.005 h^{-1}. The process behaviour is illustrated in Figure 3. As it can be observed, in the bioreactor, the CA concentration achieved a value 60% higher than that in shake flasks which in turn, with the optimized ratio, reached a value 25% higher than that the control run.

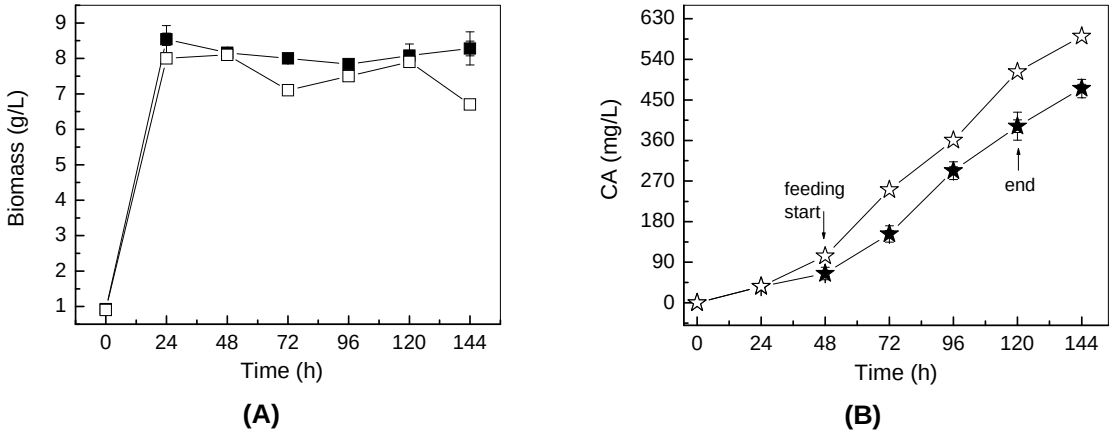

Figure 3 – (A) Biomass (□, ■) and (B) CA (☆, ★) obtained in continuous process in shake flasks (D = 0,005 h^{-1}) with glycerol:ornithine ratio 40 (glycerol 70.7 mM and Orn 1.72 mM – open symbols; glycerol 87 mM and Orn 2.12 mM – closed symbols, concentrations in the flask, at the moment of each addition).

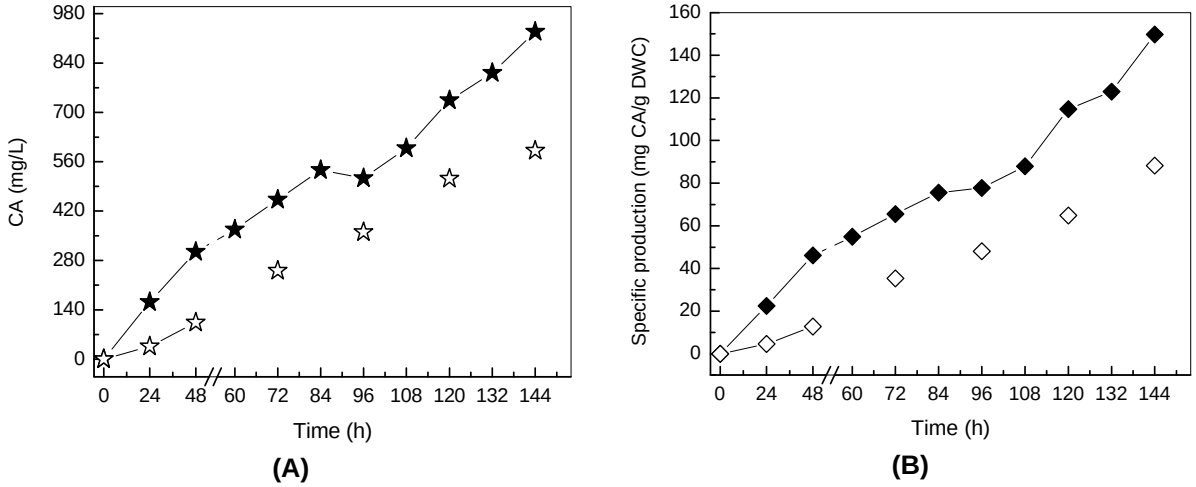

Figure 4 – Time course of (A) CA concentration and (B) specific yield in shake flasks (open symbol) and in agitated and aerated bioreactor (filled symbols), constant volume, D = 0.005 h^{-1}, glycerol:ornithine molar ratio = 40, with 70.7 mM glycerol and 1.72 mM ornithine in the flask, at the moment of each addition.

The final CA yield, in regards to glycerol consumption during the idiophase, was 3.3 mg CA/g glycerol, i.e., 57% higher than that obtained in shake flasks under the same conditions of glycerol and ornithine concentrations and 140% higher than that produced in shake flasks under the optimal concentrations evaluated from the conditions pointed out by the analysis of the factorial design results.

Topic: Integration of life sciences & engineering

Abstract

A study was made of the effect of the physicochemical properties of organic solvents on the extraction of clavulanic acid, from fermented broth, including its concentration and purification. The extraction were carried out at room temperature, at pH values of 2.0, 3.0, 4.0 and 5.0. It was observed that extraction with butanol leads to a higher Distribution Coefficient than ethyl acetate. The optimal condition with ethyl acetate occurs at pH 1.63, yielding an extraction factor of 35.6% with a distribution coefficient of 0.73.

Introduction

The isolation of clavulanic acid, CA from fermentative broth requires a series of steps due to the high contents of various contaminants that are typical in bioprocesses involving complex media. At the end of fermentation, the broth is clarified by filtration or centrifugation to eliminate mycelia, cell debris and insoluble particles, after which it is subjected to the primary extraction or direct extraction from clarified broth with organic solvent, producing an organic phase containing CA, which is subsequently isolated (Butterworth, 1982; Nabais & Cardoso, 1995). Several patents describe the extraction of clavulanic acid onto organic solvents (Cole *et al.*, 1978; Cardoso, 1998). These patents explain that CA can be extracted from fermentation broth by different procedures, and that CA is isolated when its corresponding potassium salt is formed. This salt is produced by reacting CA with potassium 2-ethylhexanoate in the solvent-rich phase, i.e., after cell removal, the resulting clarified broth is acidified to reach pH values between 2 and 3. The CA is then extracted using organic solvents such as ethyl acetate, n-butanol, methyl isobutyl ketone (MIK), n-butyl acetate, and others, and the salt is formed. Care should be taken, since clavulanic acid is highly unstable depending on the pH of the medium (pH lower than 6.2 and higher than 7.0), the presence of ammonium compounds, and the temperature (Bersanetti, *et al.* 2005). On the other hand, clavulanic acid forms unstable hygroscopic oil which cannot be used as a pharmaceutical compound (Cardoso, 1998); therefore, this purification step requires special attention to ensure an efficient process. The extraction of CA onto organic solvents is strongly affected by physicochemical properties such as solubility, polarity and dielectric constant.

This paper discusses the conditions, procedure and results obtained in the extraction of clavulanic acid from fermented broth using different organic solvents. The effect of physicochemical properties on the CA distribution coefficient, D, in the aqueous media-solvent system was determined with different organic solvents, namely, butyl acetate, ethyl acetate, methyl-isobutyl-ketone, 2-butanol and n-butanol. In addition, the effect of each solvent's physicochemical properties on the values of D was examined.

Materials and methods

Materials

Streptomyces clavuligerus ATCC 27064 fermentation broth according to Rosa *et al*. (2005). The CA was determined using the HPLC method proposed by Foulstone & Reading (1982). The concentration of contaminants was determined by spectrophotometric analysis at 280, disregarding the influence of clavulanic acid at that wavelength.

Assuming that no CA molecule is charged during the extraction and that the extraction process takes place in a perfectly stirred tank, the distribution coefficient in equilibrium can be given by Equation 1.

$$D = \frac{C_{OP1}}{C_{AP1}} \quad (1)$$

where C_{OP1} is the solute concentration in the light phase, OP (organic phase), and C_{AP} is the solute concentration in the heavy phase, AP (aqueous phase). Figure 1 illustrates the extraction process schematically.

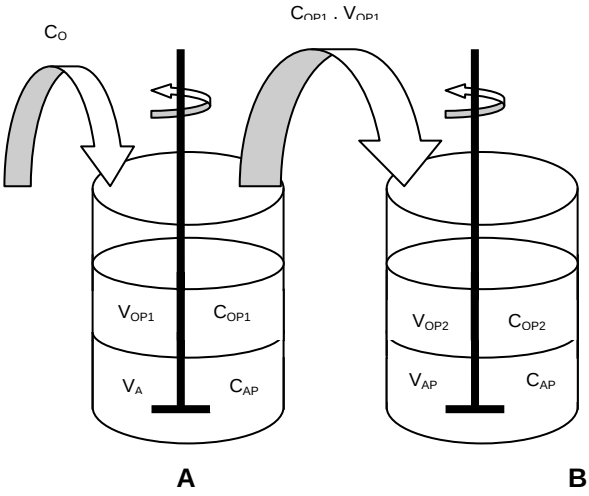

Figure 1. Scheme of the batch extraction process for clavulanic acid. A): extraction step, and B) back-extraction step

The mass balance of the extraction process can yield:

$$C_O \cdot V_{AP1} = C_{AP1} \cdot V_{AP1} + C_{0P1} \cdot V_{0P1} \quad (2)$$

$$C_{OP1} \cdot V_{OP1} = C_{AP2} \cdot V_{AP2} + C_{OP2} \cdot V_{OP2} \quad (3)$$

where C_O: clavulanic acid concentration in feed stream ($g.L^{-1}$), C_{FA1}: solute concentration of the first aqueous phase ($g.L^{-1}$), $C_{FO\ 1}$: solute concentration of the first organic phase ($g.L^{-1}$), , V_{FA1} : volume of the first aqueous phase (L), $V_{FO\ 1}$: volume of the first organic phase (L), C_{FA2} : solute concentration of the second aqueous phase ($g.L^{-1}$), $C_{FO\ 2}$: solute concentration of the second organic phase ($g.L^{-1}$), V_{FA2} : volume of the second aqueous phase (L), $V_{FO\ 2}$: volume of the second organic phase (L).Assuming

that all the CA molecules become charged during the back-extraction with neutral aqueous solution, the concentration in the organic phase becomes negligible (C_{OP2}=0). Hence, Equation 3 becomes

$$C_{OP1} = \frac{C_{AP2} \cdot V_{AP2}}{V_{OP1}} \quad (4)$$

Equation 1 can be combined with equation 4, leading to equation 5:

$$\frac{C_{AP2}}{C_{AP1}} = D \cdot \frac{V_{OP1}}{V_{AP2}} \quad (5)$$

The distribution coefficient (D) was calculated from Equation 5 for different volume and concentration ratios.The performance of the process can be analyzed in terms of such important parameters as yield Y, purification factor PF and concentration factor CF. PF is the ratio between the CF (C/C_o) of the CA and the CF of contaminants (C_T/C_{To}), according to Barboza *et al.*, 2002 and Almeida *et al.* 2003. At low pH, beta-lactam antibiotics, including clavulanic acid, usually have a protonated carboxylate group causing its low solubility in water and can be readily extracted into an organic solvent. At higher pH values the carboxylate group is deprotonated and charged, rendering the CA water soluble. The neutral concentration can be expressed according to Equation 6

$$\mathrm{Cn} = \frac{\mathrm{Co}}{(1+10^{(\mathrm{pH}-\mathrm{pKa})})} \quad (6)$$

where Cn is the concentration of the neutral form of CA and Co is the initial concentration. This equation allows for calculation of the clavulanic acid concentration in the neutral form, which remains in the heavy aqueous phase.

Results and discussion

Table 1 presents the experimental values together with each solvent's pertinent properties such as the dielectric constant, polarity, solubility in water and its molecular weight.

Table 1 Clavulanic acid distribution coefficient in different solvents and relevant properties of the solvents

Solvent	D (-)	Dielectric constant (d) (ε vacuum^{-1})	Solubility (S) (g/100g H_2O)	Molecular Weight (MW)
Butyl acetate	0.19	5.01	0.7	116.60
Ethyl acetate	0.56	6.02	8.5	88.10
Methyl isobuthyl ketone	0.32	13.11	1.9	100.16
2-butanol	0.91	15.80	9.0	74.12
n-butanol	1.38	17.51	12.5	74.12

The effects of the physicochemical properties of the organic solvents on the CA extraction are listed in Table 1. The degree of extraction is intrinsically affected by these properties. The first influence observed was on the organic solvent molecular weights. Figure 2 shows that D is inversely related to the solvent's molecular weight, i.e., the higher the MW the lower the distribution coefficient. The extraction of CA with 2-butanol and n-butanol, representing the low MW solvents, was considerably higher than with the other solvents. As for the effect of the dielectric constant on D, there is no simple or theoretical function able to relate these two variables, as indicated in Figure 3. However, if the data are divided into two regions, two directly proportional

relationships are observed. The first region encompasses the results obtained with butyl and ethyl acetate, while the second region involves the other three solvents, with a dielectric constant higher than 10. The discontinuity of the tendency for the linear increase of D with the dielectric constant is intrinsically related to the molecular structure of each solvent, particularly with regard to the functional ketone group, and with the solubility of these solvents in water. CA contains two hydroxyl groups in its structure, allowing for interactions between molecules through hydrogen bonds. The dissolution of substances like CA is favored in polar solvents in which hydrogen bonds are formed, such as alcohols. Solvents like ethyl acetate and other esters present weaker intermolecular interaction (dipole-dipole) when compared with hydrogen bonds, leading to a low dielectric constant and a weak interaction between solute (CA) and solvent, despite their higher polarity. The composition of the medium strongly affects the thermodynamic properties, which in turn affect the intermolecular interaction between the solvent and CA, producing different yields and purification factors. Figure 4 illustrates the behavior of D with solubility, S, and their relationship. The third point shown in this figure, corresponding to ethyl acetate, deviates from the linear behavior shown by the other solvents, i.e., although the solubility of ethyl acetate is nearly the same as that of 2-butanol, the dielectric constant of 2-butanol is much higher than that of ethyl acetate. However, as Figure 5 indicates, there is a well defined direct proportionality between D and the product of the dielectric constant and solubility, dxS, showing that this product can be used as a criterion to investigate other possible solvents to extract CA from aqueous media.

* not determined

The solvent n-butanol produces better results than ethyl acetate in terms of its ability to concentrate the CA solution, because n-butanol is more water-soluble than ethyl acetate; CA, in turn, is highly water-soluble, improving the extraction. The values of the concentration factor were found to decrease when ethyl acetate was used to extract CA, due to its low solubility in water. Although n-butanol presents a higher distribution coefficient for CA, the fact that it is more water-soluble actually hinders the purpose of the purification process, which is to trigger the precipitation reaction in this solvent. This is a decisive factor in choosing the most adequate solvent for the process. Therefore, ethyl acetate is potentially the solvent of choice to purify CA from fermentation broth.

In order to increase the value of the distribution constant, experiments were conducted to determine the pH at which all the CA was in the dissociated form. The results in Figure 6 indicate the pH at which the maximum CA extraction is achieved, i.e., the pH corresponding to the lowest neutral CA (clavulanate form) concentration. The neutral concentration is zero at pH 1.63; in this condition the extraction factor is 35.6% with a distribution coefficient of 0.73. Figure 7 presents the relation between D and CA in the neutral form (clavulanate), in the extraction with ethyl acetate. Therefore, at zero level of Cn, the maximum D value is 0.73.

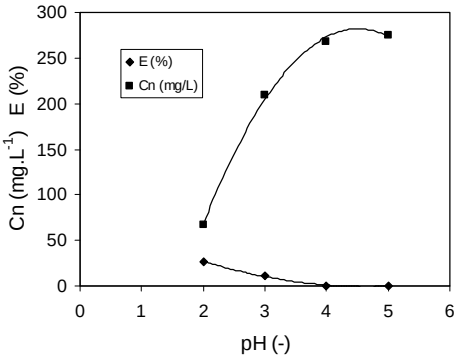

Figure 6. Variation of neutral concentration and the extraction factor, with pH, for ethyl acetate.

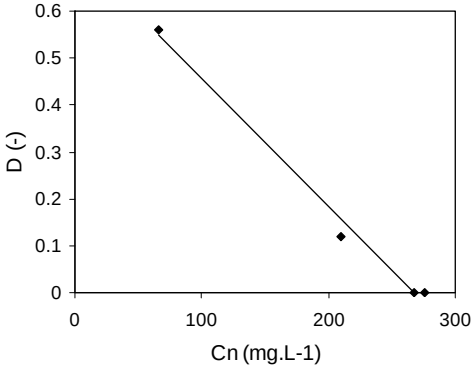

Figure 7. Distribution coefficient for clavulanic acid in ethyl acetate as a function of the neutral concentration and initial concentration.

The use of n-butanol is very attractive because it produces a high, but in this case, the use of a desiccant substance or dehydrating material is mandatory in order to withdraw water solubilized in n-butanol. The cost of removing water from the process should be a decisive factor in the choice between n-butanol and ethyl acetate as the solvent. During the extraction of clavulanic acid by organic solvents such as ethyl acetate and other esters, dipole-dipole type interactions occur. These are weak interactions, e.g., hydrogen bonding. Despite the higher polarity of some organic solvents, they usually have a low dielectric constant, which affects the CA extraction, and a weak solute-solvent interaction. These interactions may be stronger or weaker, depending on the components in the solution which are able to promote changes in the thermodynamic properties of the mixture, affecting the purification factor and yield. The extraction of clavulanic acid with n-butanol is better than with ethyl acetate, but the higher solubility of water in n-butanol impairs the final precipitation of CA.

The optimal condition for the extraction of clavulanic acid with ethyl acetate is at pH 1.63, which provides an extraction factor of 35.6% with a distribution coefficient of 0.73.

In addition, the distribution coefficient is linearly related to the product dxS, which could be used to investigate other solvents to extract CA or other beta-lactam antibiotics from fermentation broth.

Abstract

The solid-state bioprocess for microbial production of potent antioxidants is an emerging promissory biotechnology. Ellagic acid (EA) is a potent antioxidant with important physiological and functional properties. In this study EA was produced by solid state fermentation (SSF) using pomegranate husk as support and nutrient source. *Aspergillus niger* GH1 was used to release ellagic acid from ellagitannins present into pomegranate residues. SSF was kinetically monitored during 168 h. Polyphenolic content was evaluated during the fermentation, EA released was measured by HPLC. Obtained results demonstrated high rates of biodegradation of the hexahydroxydiphenic group from the ellagitannins. The highest EA accumulation was reached at the 96 h of culture (12.3 mg per gram of substrate). A yield of 0.3 g EA per g of substrate was obtained. EA formation specific rate was of $1.92x10^{-4}$ g product per g biomass per hour and the productivity of $1.29x10^{-4}$ g EA per g support per hour. SSF is an excellent alternative bioprocess for bio treatment of pomegranate residues to produce ellagic acid

1. Introduction

Ellagic acid (EA) and ellagitannins (ET´s) are naturally occurring phenolic compounds widely distributed in plants, the importance of this compound is due its diverse properties reported as potent antioxidant, anti-inflammatory, anti'-tumoral, anti-microbial, anti-viral and anti-proliferative capacities (Aguilera-Carbo et al. 2007). Major ellagitannins source are wood oak (*Quercus sp*), chesnut (*Castanea sp*) and myrobalan (*Terminalia chebula*) and some fruits like strawberry, raspberry, blueberry, cranberry, pecan and walnut.(Clifford and Scalbert, 2000). Chemically, ellagitannins consist of glucose esterified with hexahydroxidiphenic acid, gallic acid and their derivates (Shi et al., 2005). For industrial EA production from ET's, the acidic hydrolysis is the common method, however, it is an expensive and low-yield procedure (Saavedra et al. 2005). Recently, several studies on biotechnological production of EA from several plant materials have been published (Huang et al. 2007a, b, c, d; Robledo et. al. 2008; Aguilera-Carbo et al., 2008; Aguilar et al., 2008).

Our group, previously reported the first findings on fungal EA production through SSF (Aguilera-Carbó et al., 2008; Robledo et al. 2008) demonstrating that the pomegranate husk residue is an excellent alternative for EA production. Also, a biodegradation process of ET's for EA production has been proposed (Aguilera-Carbo et al. 2007). SSF is one of the most attractive alternative to management of agro industrial by-products, in this case the residues of pomegranate husk contain an interesting profile of nutrients such as large amounts of insoluble carbohydrates, small amount of protein, minerals and some remaining juice and other soluble substances favoring a rapid microbial growth. These properties can be approached for the production of high value-added metabolites. In this study we evaluated the kinetic parameters of EA production by *Aspergillus niger* GH1 using a pomegranate husk residues as support of SSF

2 Materials and methods

Powder of pomegranate husk. The samples of pomegranate fruits were collected from a rustic orchat in Sabinas, Coahuila, México. The pomegranate fruits were cleaned with water and separated in husk and seed, the husk were dried in a funnel dryer, at 60 ºC for 48 h. The dried husk was pulverized and sifted to a 30 mesh particle size in an industrial homogenizer (5 L, model LP12 Series 600-182, JR Maquinaria para mercado S.A. de C.V., México) and stored in dark and dry conditions. The material obtained was called powder of pomegranate husk (PPH).

Microorganism strain. Aspergillus niger GH1, was provided by Food Research Department collection (Universidad Autónoma de Coahuila, in Saltillo, Coahuila, México). This was previously isolated from a native plant of a semidesert zone, and selected to grow in high tannin concentrations (Cruz-Hernandez et al., 2005).

Propagation, composition media and culture conditions. The mycophill agar medium was used for propagation of fungal inoculum. The culture broth for SSF was PPH medium composed with (gL^{-1}) $NaNO_3$ 6.0, KH_2PO_4 2.4, $MgSO_4$ 1.2, KCl 1.2 and inoculated with $2x10^7$ spores per gram of PPH (support). The fermentation was carry out in tray reactors under moisture of 70 % at 30 ºC by seven days. SSF was analyzed in triplicates.

Pre treatment of material fermented for the determination. Fermented PPH was resuspended with water (30 mL) and shacked in a RIVAL immersion blender (model IB901 MX) during two cycles of 30 s, the material was transfered at 50 mL conic tubes and these were immersed in a vibrating sonic bath for 30 min (Bransonic, Model 2510R-MTH, Branson Corp, CT, USA). The material was centrifuged at 6000 rpm by 30 min, decanted and the liquid fraction was recovered (Aguilera-Carbo et al. 2007a).

Analytical methods. The biomass content was indirectly evaluated by spectrophotometry using the glucosamine content determination (Boone-Villa et al., 2008). Substrate consumption (total polyphenols content) was evaluated using the methodology reported by Makkar (1993).

Sample Preparation of ellagic acid determination and quantification by HPLC. The PPH fermented was resuspended with 30 mL of ethanol and homogenized in a submerged blender by two cycles of 30 s, the material was transfered at 50 mL conic tubes and immersed into a vibrating sonic bath by 30 min, the mixed material, an aliquot of 1.5 mL was transferred into an eppendorff tube and centrifuged at 6000 rpm (3600g) by 20 min. The supernatant was decanted and the precipitate was resuspended in ethanol. The sample was immersed into a vibrating sonic bath again for 30 min and the solution was transferred into clean test tubes and filled up to a 5 mL with ethanol and reimmersed into vibrating sonic bath for 2 h. The suspended material was filtered through 0.45 μm nylon membrane and injected into HPLC. The EA recovered was quantified by HPLC method previously reported by our group (Aguilera-Carbo et al., 2008a), The HPLC Varian Pro Star systems with a photodiode array detector (PDA Pro Star 330) was used Separation was carried out with a Prodigy ODS column (5 m; 250 x 4.6 mm, Phenomenex) and temperature of 25°C. A gradient profile of mobile phase, consisting of acetonitrile (solvent A) and 0.3% acetic acid in water (v/v) (solvent B), 7-20% A (0-7 min), 20-30% B (7-12 min), 30% B (12-18 min), 30-60% B (18-20 min), 60-100% B (20-23 min), 100% B (23-30 min) y 7% B (30-31)and 7 min for baseline stabilization was applied at a flow rate of 0.6 mL/min. The sample injection was of L. A wavelength of 254 nm was used.

Mathematical models

Biomass production was adjusted with the Velhurst-Pearl logistic equation, originally developed for population growth.

$$\frac{dX}{dt} = \mu_M \left[1 - \frac{X}{X_{\max}} \right] X \qquad (1)$$

where X is biomass density (g per L, per cm^2 or per kg), μ_M the maximum specific growth rate (h^{-1}) and X_M the equilibrium level of X for which, dX/dt = 0 for X > 0. Solution of the above equation can be written as follows:

$$X = \frac{X_{\max}}{1 + \left(\frac{X_{\max} - X_0}{X_0} \right) e^{-\mu_M t}} \tag{2}$$

where X_0 is the initial condition for X. Eq. (2) is useful to fit experimental data by Eq. (1), finding the least value of the sum of squared errors as a function of parameters, X_0, X_M and μ_M.

Substrate consumption was modeled using a two-term expression proposed by Viniegra-Gonzalez et al. (2003) as follows:

$$-\frac{dS}{dt} = \frac{1}{Y_{X/S}} \frac{dX}{dt} + mX \tag{3}$$

where S is the substrate concentration (g per L, per cm^2 or per kg), $Y_{X/S}$ the biomass yield coefficient (g X/g S) and m the maintenance coefficient (g S/g X h). Solution of Eq. (3) can be obtained as a function of X as follows:

$$S(t) = S_0 - \left(\frac{X - X_0}{Y_{X/S}} \right) - \left(\frac{X_{\max} * m}{\mu} \right) \ln \left[\frac{X_{\max} - X_0}{X_{\max} - X} \right] \tag{4}$$

where S_0 is the initial condition for substrate level, S. Eq. (4) helps to test the importance of the maintenance coefficient, m, because a state plot of $S(t)$ vs. $X(t)$ will yield a straight line with slope, $1/Y_{X/S}$, whenever m is negligible. Otherwise, a logarithmic correction will appear with coefficient, mX_M/μ_M.

Kinetics of product formation can be modeled using the equation as proposed by Aguilar et al. (2001) as follows:

$$\frac{dP}{dt} = Y_{P/X} \frac{dX}{dt} + kX \tag{5}$$

where P is the product concentration, $Y_{P/X}$ the product yield in terms of biomass (units of product per unit of biomass) and k the secondary coefficient of product formation or destruction. Eq. (5) is similar to Eq. (3), but here the coefficient k can be negative, zero, or positive, since product formation or destruction is not necessarily related to growth. Again it is possible to solve Eq. (5) as a function of biomass

$$P(t) = P_0 + Y_{P/X}(X - X_0) + \frac{kX_M}{\mu_M} \ln \left[\frac{X_M - X_0}{X_M - X} \right] \tag{6}$$

The specific growth rate (μ) was obtained by the growth plot linearization and, the slope obtention was from the straight line by minimal square regression. The specific production rate of enzyme, q_P, was defined as follows:

$$q_P = \mu_M \cdot Y_{P/X} \tag{7}$$

The specific substrate uptake rate, q_S, was defined as follows:

$$q_S = \mu_M / Y_{X/S} \tag{8}$$

$Y_{P/X}$ and $Y_{X/S}$ were estimated from the linear correlation between the ellagic acid and biomass concentration, and biomass and pomegranate husk powder, respectively.

Basic model for metabolite productivity

Enzyme productivity for fermentation systems can be expressed in different ways. In this paper it is chosen to define productivity, *Γ*, for every *t>0* as *P*(*t*)/*t*, within the overall culture medium. For example, if the porosity and the liquid content of a given SSF are known, productivity, in terms of reaction volume, can be corrected by corresponding proportional factors. Also, if enzymes are excreted to the medium and leached out at the end of the fermentation, final productivity can be estimated by taking into account the dilution factor. However, in all cases, the initial figure, related to microbial physiology is productivity defined as follows:

$$\Gamma_{\max} = \text{maximum of} \left[\frac{P}{t} \right] \quad (9)$$

That is, for a given fermentation curve, Γ_{max}, will be the maximum of the ratio between the product level per liquid broth volume, *P*, added to the system and divided by the fermentation time, *t*. In most cases, Γ_{max} will be evaluated at the peak of metabolic activities production, but, this is not always the case because of the time factor involved and the asymptotic nature of end fermentation points.

In particular, there is a term named as reference productivity ($_{Ref}$), which helps to identify the major physiological factors involved in productivity of a given experimental system that in some cases can be corrected by otter two parameters.

$$\Gamma_{Ref} = \mu_M Y_{P/X} X_{\max} \quad (10)$$

Results and discussion

In this study we evaluated the kinetic parameters of EA production by *Aspergillus niger* GH1 using a pomegranate husk residues as support of SSF. Figure 1 shows the biomass production where it was observed a lag phase during the first 50 hours of culture, After this time, the exponential growth was permanent reaching the maximal biomass concentration (0.45gg^{-1}) at 120 hours. *A. niger* GH1 grew faster and higher in comparison with the same strain grown on creosote bush leaves (Aguilera-Carbo et al., 2008). In a similar study, Vatem and Shetty (2002) reported the growth of *Rhizopus oligosporus* during the SSF of cranberry pomace for antioxidant production, where the fungus reached its maximum growth after 240 h of culture. Consumption of THP from PPH, to the first 24 hours we observed an increase on THP concentration around 20%, can must to THP solubility on the culture media, More than 40 % (0.061 gg-1) of THP were consumed at the 48 hours, while the following days polyphenols concentration remained constant, this behavior could be due to the THP degradation and the generation and consumption of polyphenols monomers. Figure 1 shows that the *A. niger* GH1 strain is capable to degrade the THP from pomegranate husk powder, in a great manner mainly due to the material chemical composition. THP content reported in pomegranate husk are monomeric ET's, such punicalagin, vascalagin and some glycosides of ellagic acid (with hexoses, pentoses, ramnoses, etc.) which are potential sources of EA (Seeram et al. 2005).

The results for EA accumulation are showed in figure 1 where it is possible to observe that during the fermentation time the maximal ellagic acid concentration was reached at 96 hours with an amount of 12.3 mgg-1 in comparison with 1.5 mgg-1 EA present at initial time (EA free present in pomegranate husk powder). These results suggest that the ET's fraction from THP, are degraded by enzymes from *A. niger* GH1 strain.

After 96 hours of fermentation it was observed a decrement in the ellagic acid concentration, have it in end of the culture 2 mgg-1.This behavior appear may be caused by interaction of EA with proteins, some metals or well, to be consumed by the fungus, but does not exist reports about the ellagic acid consumption by microorganism, It is important to consider that EA has been mentioned as inhibitor of microbial growth (Aguilera'Carbo et al. 2007). Values found in the present research for EA production are higher than those reported by Vattem

and Shetty (2003) using *Lentinus edodes* fermenting cranberry pomace (320 μgg^{-1} in extracts with ethanol at time of fermentation of 120 hours in SSF).

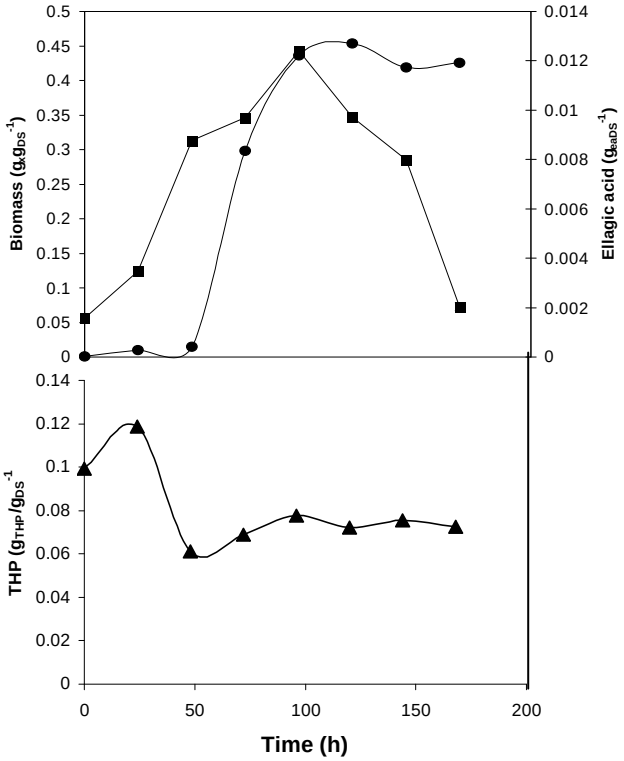

Figure 1. Mycelial growth (●), EA production (■) and THP consumption (▲).

Important advances in EA production from ellagitannins have been reported in submerged co-cultures by Huang et al. (2007a, b, c). Recently, high EA yields (24%) were obtained after optimization of the co-culture of *A. oryzae* with *Trichoderma reesei* using acorn cups extract containing up to 62% ellagitannins as substrate (Huang et al., 2007c). However, in SSC the information is limited to those studies reported by Vattem & Shetty 2002; Vattem & Shetty 2003, using cranberry pomace as support and source of ellagitannins with very low EA yields. Huang et al. (2007c) suggested for the first time, the presence of ellagitannin acyl hydrolase as the enzyme responsible of the EA accumulation, which indicates that a new tannase is involved in the biodegradation ellagitannins. Also, they reported that such enzyme had an synergistic activity with other enzymes as xylanase and cellulase to enhance the EA accumulation. However, further studies are needed to define the catalytic role and properties of this new EHA or ellagitannin acyl hydrolase detected. Aguilera-Carbo et al. (2008) reported that the SSF of *A. niger* GH1 using creosote bush ellagitannins impregnated in polyurethane foam could remarkably enhance EA accumulation.

The kinetic parameters estimated under evaluated conditions are showed in Table 1. It is important to note that a yield of 0.024 grams of EA per gram of biomass produced can be reached, however the experimental value was 6 times lower than that value. SSF of pomegranate husk can yield 0.323 grams of EA per gram of substrate, but the experimental value was of 0.299. These kinetic parameters demonstrated that it is necessary to optimize the SSF bioprocess to enhance the EA production.

Table 1 kinetics parameters on EA production in SSF

Parameter	Yx/s	Yp/x	Yp/s	Qs	Qp	P
Experimental	0.378	0.024	0.323	0.021	$1.92x10^{-4}$	$1.29x10^{-4}$
Calculated	0.357	0.004	0.299	0.279	$4.87x10^{-4}$	$8.51x10^{-5}$

Conclusions

Biotechnological EA production is a interesting field where is necessary more studies on exploration of a novel sources, byproducts carry out of optimization in EA production. The kinetic evaluation of EA production by *Aspergillus niger* GH1 using a pomegranate husk residues as support it allows kinetics parameters involved under production if this metabolite were calculated and can be considerate for the optimization of EA in SSF.

Topic: Integration of life sciences & engineering

Abstract

The Sulphite Spent Liquor (SSL) is the by-product from acidic sulphite pulping of wood. Besides dissolved sulphonated lignin (lignosulphonates), SSL normally contains notable proportion of sugars, arisen during the pulping, which can be a valuable raw material for bioprocessing. Single cell protein (SCP) is known as valuable relatively cheap product with wide applications in human and animal food staffs, as texture providing agents and flavour enhancers among others. Sugars-free SSL, from another side, may be considered as the value added product for a multipurpose utilization. In this work the possibility of single cell protein production from SSL of acidic sulphite pulping of *Eucalyptus globulus* wood (CAIMA Pulp Mill, Constancia) has been investigated employing the fungus *Paecilomyces variotii* and *Kluyveromyces fragilis* and *Candida utilis* yeasts. Different batch fermentations for SCP production were carried out with the fungus and the yeasts on both Malt Extract Medium (ME) and Yeast Medium (YM), with different concentrations of sulphite liquor. The results indicate that the fungus has a high capacity to metabolize the SSL available carbon sources for cell growth and exhibit high tolerance to the present inhibitors. Yeasts showed much lower yields on biomass production being strongly inhibited at 80% liquor medium. Fungus biomass analysis was performed and a protein content of 67 – 70% and a nucleic acid content of 17% were presented. These levels are according to requirements for SCP feed/food staffs.

1 Introduction

The shortage of protein-rich food and global existence malnourished people has forced mankind to search for alternative protein sources. Single Cell Protein (SCP) seams to be a promising alternative. SCP is the protein extracted from cultivated microbial biomass. Bioconversion of agricultural and industrial wastes to microbial protein has an additional benefit of making the final product cheaper and of representing a contribution to the environment. More over, it would make food production less dependent upon land and reduce the pressure on agriculture. Currently SCP is produced from many species of microorganisms, namely fungi and yeasts. Their rapid growth and high protein content made them excellent sources of SCP. The final product should not only be nutritious but also pass all toxicity tests to be commercialized as a food product (Anupama and Ravindra, 2000).

The Hardwood Spent Sulphite Liquor (HSSL) is the waste by-product of the pulp and paper industries that produce bleached pulps by acidic sulphite pulping of *Eucalyptus globulus* wood. After the pulping, HSSL is burned for reagents and energy recovering. HSSL contains essentially sulphonated lignin (lignosulphonates) and sugars from degraded hemicelluloses, mainly pentoses. Xylose is the main pentose present. HSSL can be used as a substrate for different bioconversion products with market value.

* Corresponding author. Tel + 351-234-370716. E-mail:abx@ua.pt

Yeasts usually exhibit a high capacity to assimilate sugar substrates through specific transport mechanisms and oxide-reductive metabolism, thus promoting a fast rate of growth (Ugalde and Castrillo, 2002).

Morphological properties of pellet and flocculated fungus biomass products could lead to relatively easy and cheap harvesting compared with yeasts or bacteria (Jin et al., 1999)

Candida utilis is especially suitable because it has a high tolerance for sulphite, can convert both hexoses and pentoses and has been used for production of several industrial products both for human and animal consumption (Rajoka et al, 2006).

Kluyveromyces fragilis has been found to have a high specific growth rate and it has been used for industrial purposes due to its physiological characteristics and bioproduct yields, in particular hydrolytic enzymes and food biomass (Schultz et al., 2006).

Paecilomyces variotii is a fungus that can be used to produce microbial protein due to its optimal performance in highly polluted residues, such as sulphite liquor. Besides monosaccharides it consumes also acetic acid of spent sulphite liquor. Protein produced by this fungus meets the aminoacids requirements for humans and animals (Almeida e Silva et al., 2003).

In this work the ability of SSL as a substrate for SCP bioproduction has been studied and a comparison between *Paecilomyces variotii*, *Candida utilis and Kluyveromyces fragilis* has been done in order to evaluate their industrial implementation.

2 Materials and Methods

Industrial thin spent sulphite liquor (SSL) was supplied by Caima Cellulose Company S.A.. SSL was prepared for the fermentation process by the addition of NH_4OH to adjust the liquor pH to 5.5 and to supplement it with a source of nitrogen. SSL was oxygenated and vacuum-filtered through glass fibre membrane filters with 1 µm pores (Filtrac.Herzberg, Ahlstrom). The liquor was analysed for dry solids (105 Cº), ash (cacinations at 525 ºC), sugars composition, acetic acid, furfural and lignosulphonate (LS) contents. Sugars analysis as alditol acetate derivatives were carried out using GC after Saeman hydrolysis of SSL. The quantification of LS was done by UV spectroscopy at 273 nm (Hitachi 2000 UV/Vis spectrophotometer). The analyse of furfural was carried out on Knauer HPLC system (Pump Mode K-1001 equipped with dynamic mixer K-1500; detector – UV fast scanning K-2600 operating at 280 nm wavelength; column – 8 µm PL Hi-PlexH 300 x 7.7 mm; eluent – water, 0.6 mL/min, 65 ºC) using phenol as an internal standard. The analysis of acetic acid was carried out on Gilson HPLC system (Pump Gilson 307; detector - refractive index Gilson 131; column - 10 µm Eurokat®; eluent - H_2SO_4 0,01N, 0.4 mL/min). Total reducing sugars concentration was analyzed by DNS method (Miller, 1959).

Paecilomyces variotii NRRL 1115 and the yeasts *Kluyveromyces fragilis* PYCC 3886 and *Candida utilis* PYCC 2541 were kept on malt extract and yeast medium (YM) agar slants at 5 ºC, respectively, and renewed every month. For the inoculum preparation, the fungus was transferred to 500 mL Erlenmeyer flasks containing 250 mL of 60% liquor and 40% malt extract medium (ME) and it was carried out for 2,3 and 6 days. For the preparation of yeasts inoculum, yeasts were transfered to 100mL Erlenmeyer flasks containing 50mL of yeast medium (YM) and the cultivation was carried out for 20h. Batch fermentations for SCP production were carried out with the fungus and the yeasts on both malt extract medium and yeast medium, with different concentrations of sulphite liquor (40, 60, 80 and 100%) at 29 ºC and 180 rpm. ME and YM pH was not adjusted – pH ~ 6.5.

Xylose, glucose and acetic acid contents were determined by referred Gilson HPLC system. Yeasts optical densities (OD) were measured using UV/Vis spectrophotometer Shimadzu at 620nm for *K.fragilis* and 640nm for *C. utilis*. Calibration curves OD versus

dry cell weight allowed to quantify biomass concentration.The fungus biomass formed during the fermentation process was assayed by direct weighing because this is an heterogeneus culture. A 0.044 mm opening sieve was used to separate the microrganism from the medium. The mycelia was washed in flowing distilled water to eliminate the residual fermentation medium, dried at 105 ºC at atmospheric pressure and weighed. After cells were freezed-dried, the crude protein content of cells was determinated with the powdered fungus by the Kjeldahl nitrogen method (N x 6.25) (Clesceri et al., 2001). Lowry method (Harris et al., 1989) was used to determine true protein content after cell disruption by sonication technique. Nucleic acids were quantified according to Sambrook et al. (1989).

3 Results and discussion

The general chemical composition of eucalypt SSL has been analysed and its composition is shown in Table 1.

Table 1. The chemical composition of SSL from acidic sulphite pulping of eucalypt wood.

Component	Concentration (gL^{-1})
Lignosulphonates	78,2 ± 0,6
Acetic acid	9,6 ± 0,1
Furfural	Traces
Ash	15,1 ± 0,2
Dry solids	150,3 ± 0,8
pH	3,4 ± 0,1
Reducing sugars	44,7 ± 0,4
D-xylose	20,5 ± 0,7
D-mannose	8,5 ± 0,3
L-arabinose	7,8 ± 0,2
D-galactose	4,5 ± 0,5
D-glucose	2,3 ± 0,1
L-rahmnose	1,6 ± 0,3
L-fucose	0,4 ± 0,2

Besides lignosulphonates, SSL contained remarkable amounts of acetic acid and sugars from degraded hemicelluloses, mainly pentoses. In particular, a high concentration of xylose was detected, which can be used as substrate for growth of biomass in order to increase the industrial profit. In addition to xylose, the acetic acid may be considered to be a suitable source of carbon for the fungus growth.

As SSL has such diverse composition certainly associated to any growth inhibition, inoculate have been made with 60% of liquor and 40% of ME. Time of inoculation has been studied making a set of equal batch fermentations assays to choose the best innoculation time between 2, 3 and six days. After these times biomass was transfered to 100% of liquor and one flask sample was analysed at day 0, 4^{th}, 7^{th} and 11^{th} from each experience. Results are presented on Figure 1.

Paecilomyces variotii grows consuming pentoses, hexoses and acetic acid and best results were reached with a 2 days inoculum where a 4 fold biomass increase was atteined: biomass production at the end of the 11 days fermentation time was 39,3 g/L.

A batch experiment with direct inoculation from Petri dish to 100% liquor was carried out and results are presented in Figure 2.

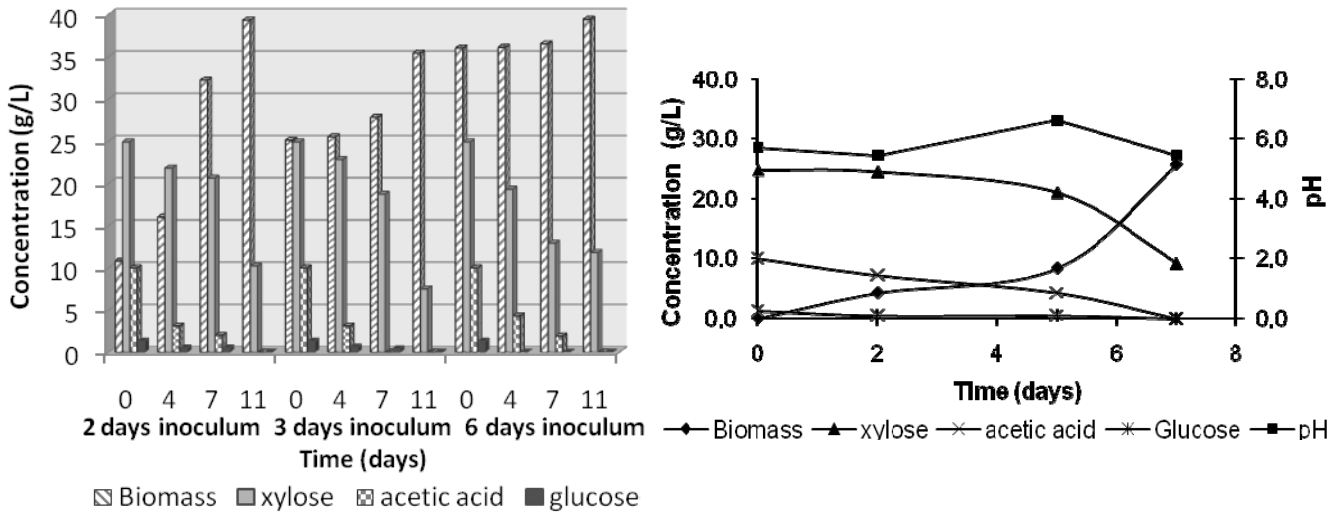

Figure 1 - *Paecilomyces variotii* 100% liquor medium fermentations.

Figure 2 - *Paecilomyces variotii* growth time course at 100% liquor medium, 0 days inoculum.

Acetic acid was completely consumed with the highest consumption rate and a low sugar consumption was verified until the 7th day. Without previous inoculum *P. variotii* showed a huge capacity to metabolize the SSL available carbon sources for cell growth and exhibit high tolerance to the traditional inhibitors acetic acid between others.

Some protein production yields (based on sugars and acetic acid carbon sources only) exceeded 100% and these results stand for the hypothesis that phenolic compouds present in the liquor such as: pyrogallol, syringic, galli and, ellagic acids represent another aditional carbon source for the fungus. *P. variotii* biomass has a high true protein content as well as crude protein that might be considered as the sum of real protein and the nucleic acids content what means the total nitrogen content (Table 1).

Table 1 - *Paecilomyces variotii* biomass analysis.

Analysis method	Kjeldahl	Lowry	Nucleic acids
	80.0%	68.1%	17.8%

Batch tests for biomass production have been carried out with *K. fragilis* with three different liquor concentrations (Table 2).

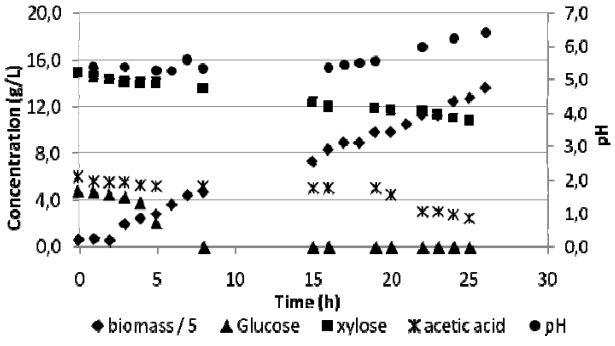
Table 2 – *Kluyveromyces fragilis* growth parameters analysis.

Medium (% Liquor)	μ_{max} (h^{-1})	$Q_{p\,max}$ (g/L/h)	$Y_{x/s\,max}$ (g/g)	Biomass (g/L)
40	0.19	0.13	0.39	3.1
60	0.19	0.07	0.94	1.0
80	0.14	0.04	0.27	0.5

It is clear that liquor has some component that is responsible for yeast growth inhibition: much lower yields on biomass production were obtained with liquor contents higher than 80%. Liquor is strongly inhibitory for yeasts.

Candida utilis was tested on 60% liquor and results are presented on Figure 3.

A growth curves comparison was established for both yeasts at the same conditions (Figure 4).



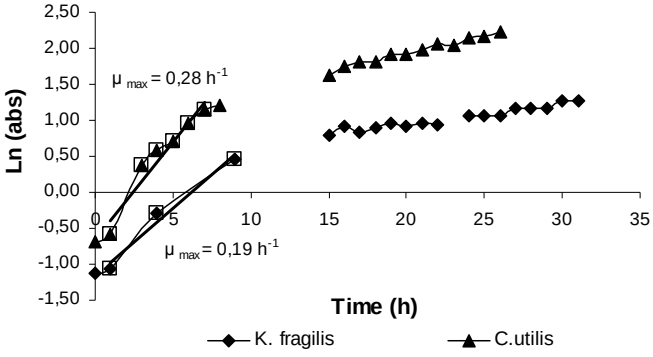


Figure 3 – Time course for *C. utilis* fermentation – medium: 60% liquor + YM.

Figure 4 - *C. utilis* and *K. fragilis* specific growth rates; medium: 60% liquor + YM**.**

The diferences in behaviour concerning sugars consumption and specific growth rates indicate that *K. fragilis* and *C.utilis* exhibit different degrees of tolerance for toxic components, such as acetic acid and phenolic compounds. *C. utilis* showed better results: 3 times more biomass than *K. fragilis* at the same conditions and 42% acetic acid consumption. Acetic acid was suggested to be a strong inhibitor for *K. fragilis*.

The potential of spent sulphite liquor as a substrate for SCP was demonstrated. After the optimization of biomass production, the resulting protein will be analysed in order to evaluate its composition, susceptibility to food and feed applications and process feasibility for the industrial implementation.

Keywords: lipases, enzymatic interesterification, milkfat modification, enzyme immobilization, polysiloxane–polyvinyl alcohol hybrid matrix
Topic: Biotechnology applied to production of new and better quality food

Abstract

Two food grade commercial preparations of lipases from *Rhizopus oryzae* and *Candida rugosa* were evaluated in relation to their potential to perform milkfat interesterification with vegetable oil. Both lipases were immobilized on polysiloxane–polyvinyl alcohol (POS-PVA) activated with sodium metaperiodate and used to catalyze the interesterification in a solvent free medium containing milkfat (80%) and soybean oil (20%). Reactions were monitored by the formation of free fatty acids using acid-base titration and the profile of triacylglycerols (TAG) analyzed by gas chromatography. Starting materials and interesterified products were analyzed in terms of saponification and iodine indexes determined by standard methods, and consistency. Both lipases resulted in changes on the triacylglycerols profile with a decrease on the TAGs concentration having C_{38} and C_{54} acyl-carbon numbers and an increase in the TAGs concentration containing C_{26}–C_{32} and C_{46}–C_{48}. It was also observed that the decrease in the concentration of the TAG C_{38}, characteristic of milkfat, was more pronounced using *Candida rugosa* lipase. On the other hand, the use of *Rhizopus oryzae* lipase resulted in higher reduction in the concentration of the TAG C_{54}, characteristic of soybean oil. The consistency expressed as yield value, decreased 27.67 and 21.12% after the interesterification catalyzed by *R. oyzae* and *C. rugosa* lipases, respectively. These results showed the potential of the selected immobilized lipases to change the TAGs profile of the milkfat-soybean oil blend, with a correspondent decrease in the consistence similar for both lipases, meaning a better spreadability of the product after the reaction.

1 Introduction

Milkfat is a very complex food, constituted by a broad range of long and short chain fatty acids in the form of triglycerides. This complexity is responsible for its unique physical and organoleptical characteristics. Nevertheless, the consumption of milkfat has been declined due to its high degree of saturation, price and high percentage of hypercholesterolemic fatty acids (Balcão and Malcata, 1998). An alternative to overcome such drawbacks was to replace milkfat by partial hydrogenated vegetable oils, in the form of margarines and spreads. However, vegetal oil hydrogenation process generates also high amount of *trans* fatty acids as by-product. The ingestion of these fatty acids has been found to increase both the low density lipoprotein cholesterol (LDL-cholesterol), known as “bad” cholesterol, and decrease the high density lipoprotein cholesterol (HDL-cholesterol) known as “good” cholesterol. This has motivated the food industry to reformulate products that could take advantage of the beneficial effects of milkfat as conjugated linoleic acids (Haug et al., 2007).

An interesting approach is to blend milkfat with vegetable oils either in the presence (interesterification reaction) or without catalyst (physical mixture). The former yielded a product with better spreadability properties and can be catalyzed by chemical or enzymatic routes. Enzymatic interesterification is advantageous in comparison to chemical

* Corresponding author. Tel + 55-1231595149. E-mail:jsant200@yahoo.com.br

interesterification because enzymes (lipases) allow carrying out processes under mild reaction conditions (temperature and pressure) that results better preservation of the milkfat flavor (Rodrigues and Gioielli, 2003).

To fully exploit the technical and economical advantages of lipases, it is recommended to use them in an immobilized form to reduce the cost and the poor stability of the soluble form. There are many methods available for biocatalyst immobilization that span from binding on prefabricated carrier materials to incorporation into in situ prepared carriers. Recently, the potential of using a hybrid matrix of Polysiloxane-Polyvinyl Alcohol (POS-PVA) obtained by sol-gel process for lipase immobilization has been demonstrated in our laboratory (Paula et al., 2008).

Thus, in this work, two food grade commercial preparations of lipases from *Rhizopus oryzae* and *Candida rugosa* were evaluated in relation to their potential to perform milkfat interesterification with soybean oil. Both lipases were immobilized on POS-PVA activated with sodium metaperiodate and used to catalyze the interesterification of a solvent free medium containing milkfat (80%) and soybean oil (20%).

2 Materials and Methods

2.1 Materials

Food grade commercial lipase samples from *Rhizopus oryzae* (Lipomod L036P) and *Candida rugosa* (Lipomod L034P) were kindly donated by Biocatalysts (Cardiff, Inglaterra). Lipase samples were immobilized on POS-PVA activated with sodium metaperiodate. Milkfat was obtained from complete fusion, in microwaves oven, from commercial butter (Paulista Extra without salt, purchased in a local market) at temperatures from 50 to 65°C, to disperse the emulsion, followed by centrifugation and separation of the aqueous phase. Commercial soybean oil (Liza Type 1 Extra filtered 5 times, purchased in a local market) was utilized without additional treatment. Other reagents were tetraethoxysilane (TEOS), acquired from Aldrich Chemical Co. (Milwaukee, WI, USA); polyvinyl alcohol (PVA, MW 72,000) and polyethylene glycol (PEG, molecular weight 1500), supplied by Reagen (Rio de Janeiro, RJ, Brazil). All other chemicals were of analytical grade.

2.2 Support synthesis, activation and immobilization procedure

The polysiloxane-polyvinyl alcohol (POS-PVA) hybrid composite was prepared by sol-gel technique according to the methodology described by Paula et al. (2008). The resulting POS-PVA particles was activated with sodium metaperiodate (Cunha et al., 1999) and used to immobilize both lipases at fixed loading (0.20 g of lipase per gram of support). Aqueous polyethylene glycol (PEG) 1500 solution (5 mg/mL) was added together with the enzyme at a fixed amount (5mg/g of support). Lipase-support system was maintained in contact for 24h at 4^{o}C. Immobilized lipase derivatives were filtered and thoroughly rinsed with hexane.

2.3 Interesterification of milkfat with soybean oil

The interesterification reactions were performed in duplicate under inert nitrogen atmosphere, in cylindrical glass reactors (100mL), containing 50g of milkfat and soybean oil blends at proportions of 80:20. Mixtures were incubated with immobilized derivatives on POS-PVA at proportions of 10% (w/w) in relation to the total weight of reactants involved in the reaction media. Reactions were carried out for a maximum period of 72h, in a rotary shaker (170 rpm) at 45ºC. The progress of the reaction was followed by the determination of the saponification and iodine indexes, triacylglycerols (TAGs) composition and consistency of the interesterified products.

2.4 Free fatty acids and indexes of saponification and iodine

The content of free fatty acids was determined according to standard method Cd 3d-63 (American Oil Chemists' Society, 2004). The saponification and iodine indexes were determined by the standard methods Cd 3-25 and Cd 1b-87, respectively (American Oil Chemists' Society, 2004).

2.5 Determination of the triacylglycerols (TAGs) profile in interesterification reactions

The determination of the TAGs was carried out using a gas chromatography (Varian - Model 3800), with a column packed 3% OV1 SILPT-WBM 100/120 MESH in Silco Var, Restek (purchased from the Frankel Commerce of Ltd Analytic Instruments, São Paulo, SP), operating under conditions previously established (Paula, 2008).

2.6 Hydrolysis degree (H, %)

The hydrolysis degree was calculated according to the equation 2.1:

$$H(\%) = \frac{AG_f}{AG_t} \cdot 100 \qquad (2.1)$$

where: AG_f = total concentration of fatty acids formed in the reaction (mM); AG_t = total concentration of fatty acids that would be liberated, considering the total hydrolysis of triacylglycerols in the reaction medium (mM).

2.7 Interesterification Degree (I, %)

The interesterification degree was calculated according to the equation 2.2:

$$I(\%) = \frac{\sum (TAG_I)_t - \sum (TAG_I)_0}{\sum (TAG_D)_0} \cdot 100 \qquad (2.2)$$

where: TAG_I = concentration (mM) of the triacylglycerols in which concentration increased during the reaction; TAG_D = concentration (mM) of the triacylglycerols in which concentration decreased during the reaction. The index "t" and (0) represent the concentrations of TAG in any time of reaction and in the initial reaction mixture, respectively.

2.8 Consistency

The consistency of the raw materials and interesterified products were determined utilizing a texture analyzer (Model QTS-25 Brookfield, Middleboro, MA, USA) controlled by the Texture Pro software v. 2.1. Samples were heated in microwave oven (55–62ºC) for the fusion of the crystals, and conditioned in cubic silicone forms (edge of 25mm) during 48h, at 10ºC. The probe TA15 was used, corresponding to an acrylic cone with angle of 45º. Tests were under the following conditions: total of cycles 1, distance = 10mm, speed = 120mm/min, time = 5s; determination of the force in compression (gf), in duplicate.

The results were used to calculate the "yield value", defined according to Equation 2.3 (Deman and Deman, 2002):

$$C = K \cdot \frac{W}{p^{1.6}} \qquad (2.3)$$

where: C = "yield value" (gf/cm); K = a constant depending on cone angle (4700 for 45º); W = maximum compression force (gf), for 5s; p = penetration depth (in 0.1mm).

3 Results and discussion

Table 1 shows the saponification and iodine indexes for the interesterified products obtained in the reactions catalyzed by lipases from *R. oryzae* (L036P) and *C. rugosa* (L034P). Values for pure milkfat and physical blend of milkfat with soybean oil are also shown in Table 1.

As can be noted, similar saponification indexes (218.91 and 218.29 mgKOH/g) were found for both interesterified products. Such results can be understood by considering that the interesterification reaction is responsible for changes in the fatty acids positions but cannot afford alterations on the molecular weight of the raw materials.

Table 1. Saponification and iodine indexes for pure milkfat, milkfat and soybean oil mixture (80%:20%) and interesterified products.

Index	Milkfat	Mixture	Interesterified Products	
			L036P (*R. oryzae*)	L034P (*C. rugosa*)
Saponification (mgKOH/g)	230.17	209.29	218.91	218.29
Iodine (gI_2/100g)	34.41	49.61	49.27	50.59

Interesterified products showed iodine indexes higher than the one observed for pure milkfat (34.41 gI_2/100g). This can be explained by the fatty acids composition of soybean oil which has more unsaturated fatty acid proportions than milkfat and, therefore, the mixture of these two components resulted in higher iodine index. Besides this, values for interesterified products were similar to the one given by the physical raw materials blend (49.10 gI_2/100g). As already mentioned, the interesterification reaction is responsible only for changes in fatty acids positions, resulting in products that present the same fatty acids composition.

Figure 1 shows the composition profile in TAGs for the interesterified products, pure milkfat and raw materials blend. As can be observed, the addition of soybean oil to milkfat resulted in a reduction of TAGs C_{28}–C_{46} concentrations and an increase in long chain TAGs (C_{52} and C_{54}) concentrations, which are presented in the soybean oil in high amounts. The comparison between the composition of the interesterified products with the initial raw materials blend (Figure 1) showed a decrease in the triacylglycerols level with a long chain (C_{54}) and increase in the content of the triacylglycerols C_{26}–C_{32} and C_{46}–C_{48}, after the process. A decrease in the TAG C_{38} concentration, characteristic of the milkfat, was observed mainly for *Candida rugosa* lipase, whereas for the lipase from *Rhizopus oryzae* higher reduction was noted for TAG C_{54} concentration, characteristic of soybean oil.

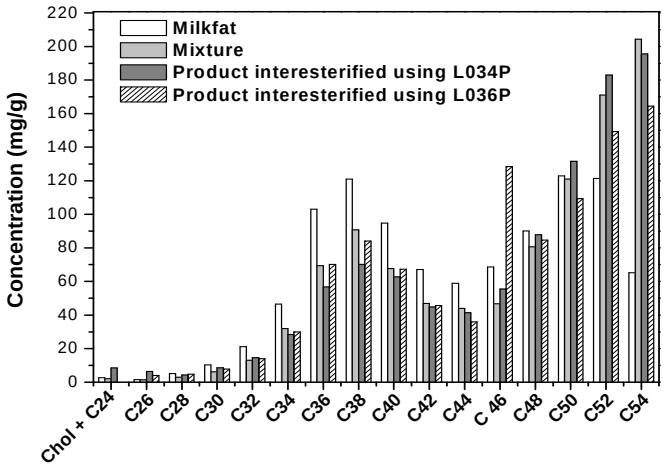

Figure 1. Comparison between TAGs composition for interesterified products, pure milkfat and raw materials blend (TAGs were identified by the sum of the number of carbons in the fatty acid residues).

From the TAGs profile, the interesterification degree (%) was calculated according to equation 2.2, and this result was compared to the hydrolysis degree (%), as shown in Figure 2. As observed, the enzymes L034 (Figure 2.a) and L036 (Figure 2.b) resulted in a maximum interesterification degree of 9 and 14 %, in 72 and 48 h, respectively.

To achieve high yields in the interesterification reactions the water content in the bulk liquid phase should be kept as low as possible. Although a small amount of water is needed for

maintenance of the enzymatic activity (Lamboursain et al., 1996), high levels of water may lead to the formation of free fatty acids, mono and diglycerides, instead of TAGs redistribution. In this work, immobilized derivatives containing 10% of water were used and this fact can explain the hydrolysis degree (about 5 %) obtained in the reactions catalyzed by L034P and by L036P, as observed in Figure 2. This may suggest that additional strategy should be taken into consideration to control the water content aiming to avoid the undesirable hydrolysis of the TAGs.

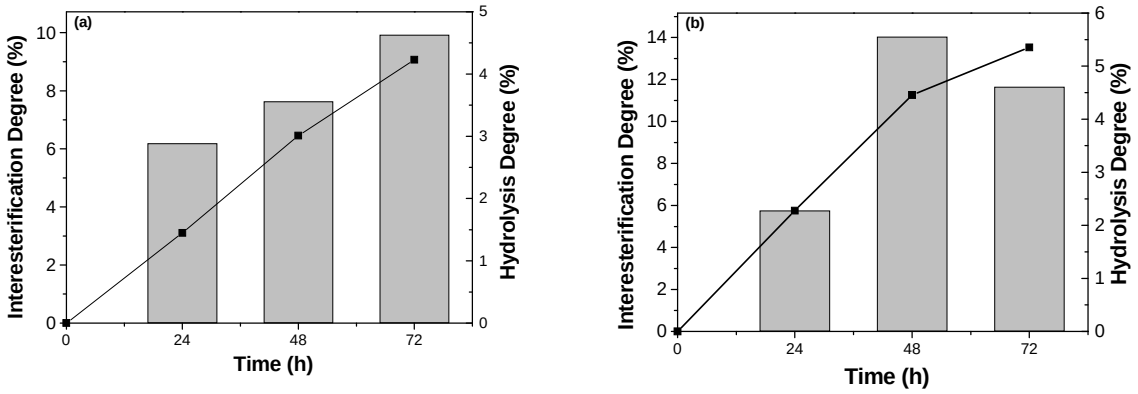

Figure 2. Interesterification (bars) and Hydrolysis (●) Degree for interesterification reactions catalyzed by lipases from *Candida rugosa* (a) and *Rhizopus oryzae* (b).

The consistency values for the interesterified products, pure milkfat and raw materials blends, measured at 10ºC are displayed in Figure 3. These results indicated that a reduction higher than 50% can be achieved by simply adding soybean oil to the pure milkfat. Rodrigues et al. (2003) also described similar behavior for milkfat and corn oil blends and explained this assuming that the addition of liquid oil to the milkfat dilute the fat crystals, giving, as a consequence, a more fragile structure.

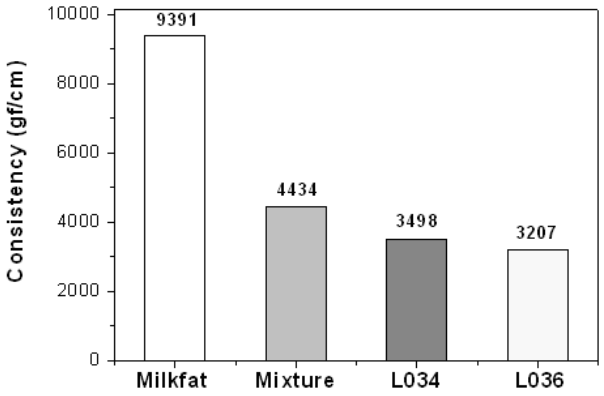

Figure 3. Consistency of the interesterified products compared to the milkfat and the mixture of the raw materials

In relation to the consistency of the physical raw materials blend, the interesterification reactions catalyzed by *R. oyzae* and *C. rugosa* lipases provided a decrease in the consistency in the order of 28 and 21%, respectively. Such reductions can be explained either by the incorporation of the unsaturated fatty acids present in the soybean oil in the TAGs of the milkfat or by the presence of small amounts of mono and diglycerides, which can behave like emulsifiers and can modify the texture products (Kaewthong et al., 2005).

4 Conclusions

Results showed the potential of the evaluated lipases for the interesterification of milkfat with soybean oil. The use of these enzymes resulted in the modification of the triglycerols composition and the interesterified products presented a reduction of 27.67 and 21.12% in the consistency values for reactions catalyzed by *R. oyzae* (L036P) and *C. rugosa* (L034P) lipases, respectively. Therefore, the feasibility of using these lipases to reduce the milkfat consistency and turning the milkfat more spreadable under cooling temperature has been demonstrated.

Topic: Clean Technology, Valorization of Amazonic Products
Presentation Format: Poster

Abstract

The present work involves enzymatic hydrolysis of crude buriti oil, for further extraction and concentration of β-carotene. In the hydrolysis process, the performance of commercial lipase Lipozyme TL IM was evaluated. The analyzed parameters in the hydrolysis process were temperature, enzyme quantity (enzymatic activity) and ratio of buriti oil / water. The experimental conditions were established based on an experimental design in order to set the maximum free fatty acids contents and the minimum loss of carotenoids.

The results were analysed for the free fatty acids content using titration; total carotenoids through spectrophotometry and its composition by HPLC, employing a YMC ODS-A column with a mobile phase of acetonitrile/methanol/THF (50/45/5). The optimized conditions of the enzymatic hydrolysis were 31.2°C (temperature), 25 U (enzymatic activity in 8 mL of mixture volume), 2.33 (ratio oil/water), at 300 rpm, during 4 hours of reaction. After the hydrolysis of the oil, some methods were tested to separate the formed fatty acids from the carotenoids, as partition with ethanol and winterization, increasing the β-carotene concentration in the final product.

1 Introduction

β-carotene is the main source of provitamin A and is widely used as a food colorant and nutritional supplier. The global market for carotenoids, which was of US$ 887 millions in 2005 and has been growing at an yearly rate of 3%, is estimated to surpass US$ 1 billion in 2009, being β-carotene responsible for almost 30% of this market (Fraser & Bramley, 2004).

Most of the β-carotene sold in the world is produced by chemical synthesis from β-ionone, but a small amount is manufactured using biotechnological processes, based on different microorganisms, such as fungi (*Blaskelea trispora* and *Phycomyces blaskeleeanus*), yeasts (*Rhodotorula glutinis*), bacteria (*Flavobacterium multivorum*) and microalgae (*Dunaliella salina* and *D. bardawil*) (Bhosale & Bernstein, 2004; Dufossé *et al*, 2005; Kuzina & Cerdá-Olmedo, 2007; Maldonade *et al*, 2008).

Some oleaginous fruits, such as palm (*Elaeis guineensis*) and buriti (*Mauritia vinifera*), present high concentrations of carotenoids, specially β-carotene. Buriti is a palm tree that grows wild in different areas of Brazil, and has been traditionally used for the preparation of beverages and candies in the Amazon area. The recent interest about other natural sources of β-carotene stimulated the development of processes to extract the carotenoid-rich oil of the buriti fruit. Most processes, however, are still based on the conventional technologies for pulps, including drying and pressing the oil off the pulp (Rodriguez-Amaya, 2001; Santos, 2005).

* Corresponding author. Tel + 55-21-25627572. E-mail:alice@eq.ufrj.br

Due to similarity between the physical properties (solubility, polarity, molar massr) of carotenoids and triglycerides, besides low selectivity of most physical separation methods currently used for carotenoids extraction, as well as irreversible structural alterations caused by chemical methods, the search for more specific and mild methods to the extraction of carotenoids contained in vegetable oils is a great challenge (Güçlü-Üstündag & Temelli, 2004).

The present work consists in a bioprocess development by enzymatic hydrolysis of crude buriti oil using commercial lipase Lipozyme TL IM, for further extraction and concentration of β-carotene.

2 Materials and Methods

The crude buriti oil RF3800 was gently provided by Beraca Sabará®. The commercial lipase utilized was Lipozyme TL IM from *Thermomyces lanuginosus* from Novozymes®, which presented 690,24 ± 6 kU/kg of lipolytic activity, measured as Meirelles (1997).

Some conditions for the enzymatic hydrolysis were initially constant as reaction time (4 h), agitation speed (200 rpm), reaction volume (8 mL) and amount of alumina, used as fatty acid adsorbent, (10 % w/v). Others parameters, like temperature, enzyme quantity (activity) and ratio buriti oil/ water, were evaluated (Table 1) with a central composite experimental design with 3 levels and 3 central points.

Table 1 – Value range utilized for parameter optimization of enzymatic hydrolysis

Parameters	-1,68	-1	0	+1	+1,68
Temperature (°C)	25	29	35	41	45
Enzymatic Activity (U)	1	10,7	25	39,9	50
Ratio Oil/Water	1/1 (1)	7/5 (1.4)	2/1 (2)	13/5 (2.6)	3/1 (3)

For achieving higher yiels in free fatty acids content, additional tests were realized, which the conditions (temperature and ratio oil/water) obtained in the experimental design were maintained, but considering enzyme activity within small intervals (5, 15, 25, 35, 45, 55 and 65 U), besides agitation speed (200, 300 and 400 rpm) and reactional time (0,5, 1, 1.5, 2, 3, 4, 6 and 8 h). After this, the organic phase (carotenoids and oil) were separated from the other components (water, glycerol, lipase, saturated fatty acids and alumina). Then, desacidification and concentration were tested by partition with ethanol (Gonçalves *et al*, 2007) and winterization.

The results were analyzed for the free fatty acids contents using potentiometric titration (Kanicky & Shah, 2002; Osawa & Gonçalves, 2006); and total carotenoids using spectrophotometry (Rodriguez-Amaya, 2001).The samples were also analyzed according to the composition of carotenoids in HPLC. The separation was carried out with a 100 x 4.6 i.d. mm YMC-Pack ODS-A column (5 mm particle size), using as mobile phase acetonitrile/methanol/THF (50/45/5 v/v/v), with addition of 0.05% triethilamine to methanol. The flow rate was 1.0 mL/min, and the absorbance was detected on 450 nm. The standards used was obtained by open column chromatography separation, in which activated magnesium oxide – diatomaceous earth mix was employed. Initially was added the unsaponifiable fraction of crude buriti oil to the column, and then eluted with petroleum ether in concentrations varying from 4 to 20 of diethyl ether. The fractions obtained were α-carotene, β-carotene and γ-carotene. These carotenoids were confirmed by scanning in the visible spectre in DR400 UV Hach spectrophotometer (Godoy & Rodriguez-Amaya, 1995; Rodriguez-Amaya, 2001; Ribeiro, 2008). The results of experimental design were analyzed employing software STATISTICA 6.0.

3 Results and Discussion

The crude buriti oil presented a high content of unsaturated fatty acids, mainly oleic acid (75%), and carotenoids, about 1800 ppm (Table 2), which carotenoids composition can be observed in Figure 1 (Ribeiro, 2008).

Table 2 – Major components in crude buriti oil

Components	%
Fatty acids	
Saturated	22.2
Unsaturated	77.8
Carotenoids	
β-carotene	76.8
α-carotene	8.8
γ-carotene	4.5

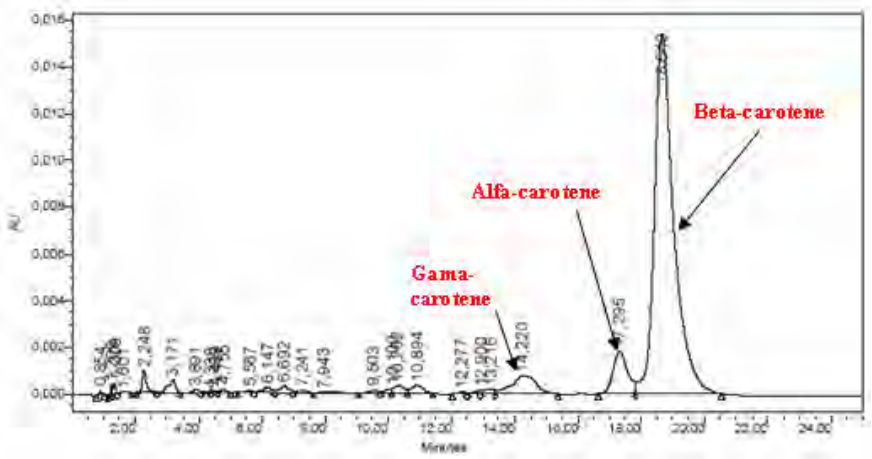

Figure 1 – Carotenoid composition profile of crude buriti oil

The results obtained in the central composite experimental design referred to the enzymatic hydrolysis with Lipozyme TL IM were decpited in the Table 3. The optimized conditions obtained were: 31.2 °C (temperature), 21.6 U (enzymatic activity) and 2.33 (ratio oil/water), which using the regression coefficients, the variables free fatty acid and carotenoids could be calculated, resulting in 6.48% and 1749 ppm, respectively.

Table 3 – Results of enzymatic hydrolysis of crude buriti oil using central composite design

Assays	T(°C)	Activ(U)	Oil/Water	%FFA	Carot. (ppm)
1	29.0	10.7	1.4	62.89	1539
2	29.0	10.7	2.6	56.58	1810
3	29.0	39.9	1.4	73.61	1561
4	29.0	39.9	2.6	73.04	1732
5	41.0	10.7	1.4	62.53	1580
6	41.0	10.7	2.6	52.83	1692
7	41.0	39.9	1.4	**76.46**	1609
8	41.0	39.9	2.6	61.20	1609
9	25.0	25.0	2.0	60.11	1547
10	45.0	25.0	2.0	66.06	1570
11	35.0	1.0	2.0	18.78	1814
12	35.0	50.0	2.0	72.00	1602
13	35.0	25.0	1.0	64.24	1631
14	35.0	25.0	3.0	67.86	1596
15 (C)	35.0	25.0	2.0	66.06	1728
16 (C)	35.0	25.0	2.0	62.61	1746
17 (C)	35.0	25.0	2.0	68.87	1720

High free fatty acids yield could be explained by tridimensional structure of lipase active site (Gutierrez-Ayesta *et al*, 2007) or also by possible hiperactivation generated by immobilization method used in the production of Lipozyme TL IM, which could leave the active site always exposed and activated (Cunha, 2007). Devos *et al* (2006) performed a comparation between 12 lipases in the hydrolys of algal phospholipids, showing that Lipozyme TL IM also generated free fatty acids yields of 75%, although using higher reaction time (24 h), agitation speed (800 rpm), enzyme quantity (1% w/v) and ratio between organic and aqueous phases (1/10).

Since the enzymatic activity was the only parameter statistically significant in the oil hydrolysis, it was tested in small intervals, which determined that better condition was 25 U (0,47% w/v), without great carotenoids loss (Figure 2).

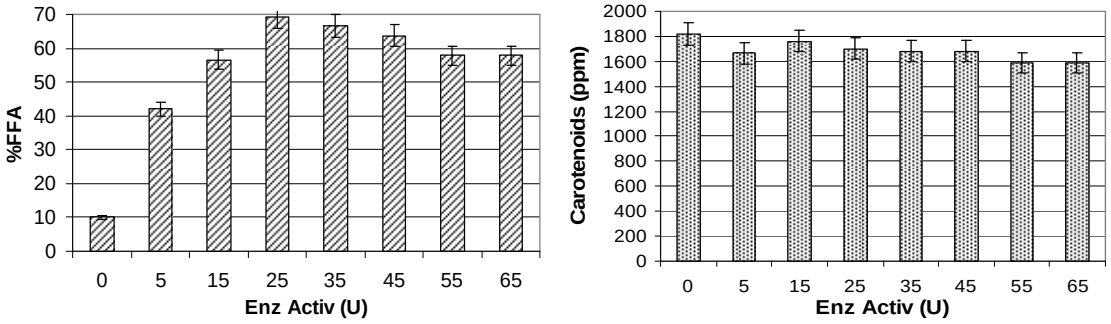

Figure 2 – Optimization of enzyme quantity in the enzymatic hydrolysis of buriti oil

Still objecting a higher oil hydrolysis, different agitation speed were tested in the system to increase the interfacial area and facilitate lipase action. The chosen speed was 300 rpm due to the increased free fatty acids yields (about 75%), with carotenoid loss slightly lower than obtained in 40 rpm (Figure 3).

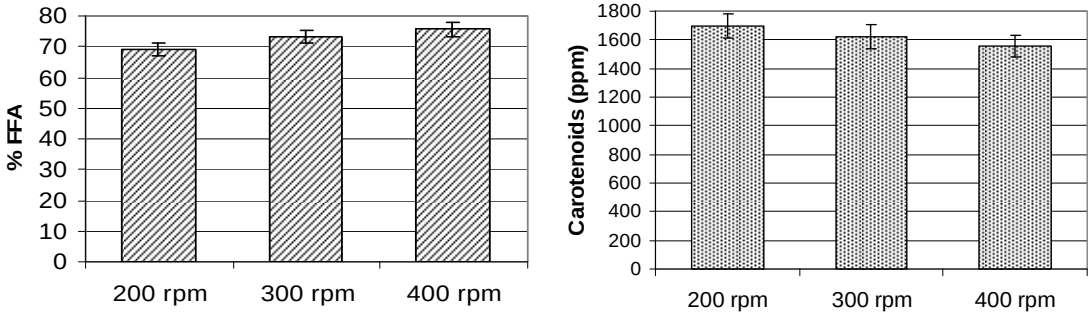

Figure 3 – Evaluation of agitation speed in the enzymatic hydrolysis of buriti oil

Maintaining all the previous conditions, the reaction hydrolysis kinetics was evaluated, and then observed that, in 4 h of reaction, the oil hydrolysis was stabilized (Figure 4). Probably, the free fatty acids yields remained about 75% due to pH alteration, which reached values near to 5, leading to a possible lipase inhibition.

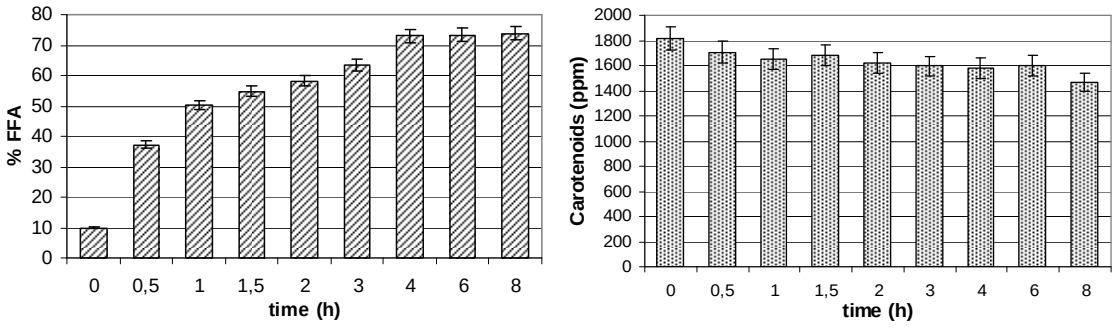

Figure 4 – Optimization of reactional time in the enzymatic hydrolysis of buriti oil

After phase separation, two methods of carotenoids concentration were tested. First was the partition with ethanol, which, in 15 min, the fatty acid concentration in alcoholic phase was 10%. Gonçalves & Meirelles (2004) reached concentration of 53%, but in their work was included stand-by step of 24 h to equilibrate the system, and the quantity of fatty acids in the sample was near to 4%.

In relation to carotenoids, just 2% were distributed to ethanolic phase when crude buriti oil was used. Gonçalves et al (2007) verified the carotenoids of palm oil distribute to the alcoholic phase between 1.6 a 2.7%, which could increase if the water quantity in the system was lower, for example with anhydrous ethanol the carotenoids partition rise to 13%. In Figure 5, the variation of free fatty acids and carotenoids was observed since the ending of enzymatic process (1), the separation of organic and aqueous phases (2), and the sucessive extraction of organic phase with ethanol (3).

In this process, the carotenoid loss was of 4.4%, and practically duplicating the total quantity after the sucessive extraction. The fatty acids was reduced to 30%, indicating that more extraction will be needed.

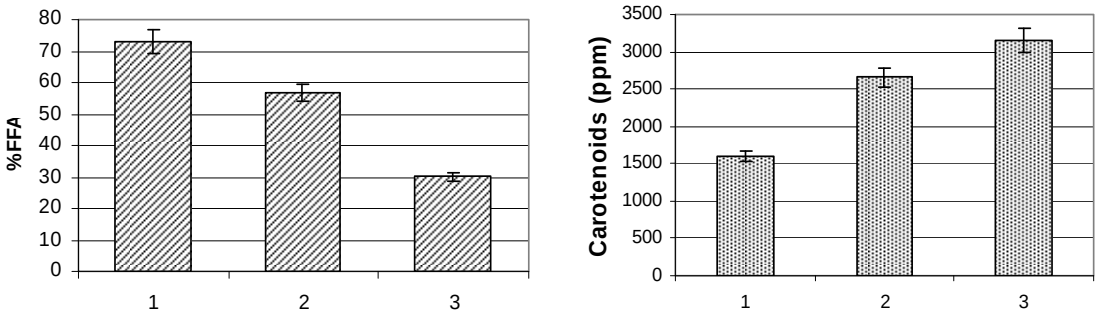

Figure 1 – Evaluation of free fatty acids and carotenoids during the post-processing of buriti oil

In winterization process, two phases were obtained: the first solid with 43% of free fatty acids and 3186 ppm of carotenoids, while the other liquid with 26% of free fatty acids and 3910 ppm of carotenoids (Figure 6).

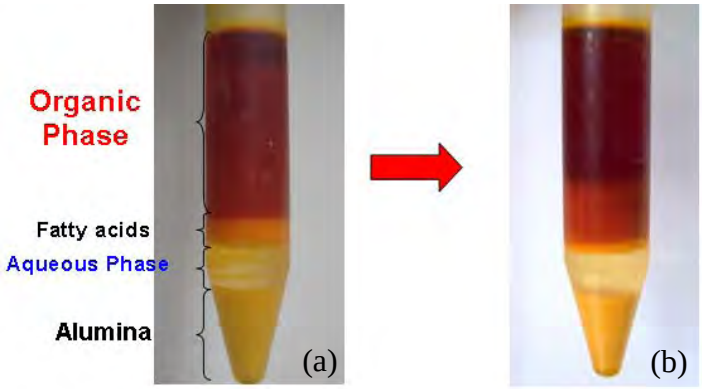

Figure 6 – (a) Before and (b) after the winterization of buriti oil

4 Conclusions

The enzymatic hydrolysis followed by partition with ethanol or winterization demonstrated to be a feasible method for extraction and concentration of carotenoids. This could facilitate a generation of food products rich in carotenoids, reducing the problems of hipervitaminose A in the world.

Enzymatic inulin hydrolysis using PVA-based matrices

Pedro Fernandes*, Stefano Cattorini, Joaquim M.S. Cabral

Keywords Hydrogels, polyvinyl alcohol, inulin hydrolysis, inulinase, encapsulation
Topic: Integration of life sciences & engineering.

Abstract

Inulinase form *Aspergillus niger* was immobilized into poly(vinylalcohol) hydrogel lens-(Lentikats®) and hemispherical-shaped capsules, based on LentiKat® liquid. Temperature and pH profiles, as well as kinetic constants were determined, for both free and immobilised enzyme. A broader-shaped curve was observed for the pH-activity profile when immobilized forms were matched to the free form. The K_M of inulinase increased roughly 2-fold upon immobilization, suggesting diffusion limitations of inulin inside the gel. Long term operation with immobilized enzymes is not viable given the decay of mechanical strength of the support above 55ºC. The hemispherical form of the immobilized enzyme displayed long-term operational stability in repeated batch-mode runs, for it allowed for 20 runs at 50ºC, with a final decay of product yield in 20%. When Lentikats® were used, similar decay was roughly of 70%.

1 Introduction

Inulin is a linear-linked fructose polymer that occurs as reserve substrate in Jerusalem artichoke, chicory or dahlia tubers. This polymer is an acknowledged source for the production of fructose syrups, in alternative to the multi-enzymatic starch hydrolysis or the less favored inverted sugar production (Ricca et al., 2007). Inulin hydrolysis can be performed chemically, but this approach leads to unwanted by-products and colored compounds, shortcomings that can be overcome if the enzymatic route, performed by inulinases, is used (Vandamme and Derycke, 1983). The enzymatic approach is further favored if a suitable immobilization method can be used. In the food industry this requires for a readily available support and simple immobilization procedures, to comply with the need to cut down costs and complexity (Walsh, 2007). Immobilization of inulinase for fructose production has mostly relied in covalent and ionic binding methods, although entrapment into alginate, chitin and casein has also been reported (Gill et al. 2006, Ricca et al., 2007) Polyvinyl alcohol is a synthetic polymer that can be used to form hydrogels, and combines the biocompatibility of natural polymers with high mechanical strength (Angelova and Hunkeler, 1999). Several methods have been developed to produce PVA capsules. One of the most recent relies on the controlled drying of a PVA based hydrogel (LentiKat® liquid), and subsequent chemical stabilization, leading to lens-shaped particles (Vorlop and Jekkel, 1999). This methodology has been applied to the hydrolysis of di- and oligosaccharides (Rebros et al., 2006, 2007), but not to polysaccharides such as inulin. In the present work two procedures of inulinase immobilization for inulin hydrolysis to fructose, based in the use of LentiKats® liquid, were evaluated: gelation of PVA by controlled drying, yielding lenticular shaped particles, and a novel approach where PVA is extruded into polyethylene glycol (PEG), where gelification occurs instantaneously in the form of hemisphere-like capsules. The kinetic parameters, pH and temperature profiles of free and both forms of immobilized inulinase were matched and the long term stability of the two forms of the immobilized enzyme was evaluated.

2 Materials and methods

Fructozyme L, a commercial preparation of inulinase from *Aspergillus niger*, was provided by Sigma, polyethylene glycol (PEG) 600 was from Fluka, LentiKat® liquid, a PVA-based material, and LentiKat® stabilizer were from GeniaLab and inulin from chicory (Fibruline Instant) was a kind gift from Cosucra. All other chemical were of analytical grade from various suppliers.

Inulinase immobilization

Entrapment of inulinase in Lentikats® was performed according to the protocol provided by GeniaLab (http://www.geniaLab.de/download/tt-english.pdf). Briefly, the LentiKat® liquid was heated at 95ºC and then cooled to 40ºC. The enzyme suspension (0.5 ml of a ten-fold, 100 mM acetate buffer, pH 4.5, diluted commercial preparation) was added to 10 ml of the LentiKat® liquid and thoroughly mixed. The liquid was extruded through a needle (Therumo, 20 G x 2") into Petri dishes to form small drops. These were left at room temperature, until roughly 28% of the initial mass remained. LentiKat® stabilizer was then poured into the Petri dish, and after 2-3 minutes, the suspension was transferred to a flask, about a 10-fold volume of stabilizer further added, and the whole stirred for 2 hours. The lens-shaped particles, with 3-4 mm diameter, were harvested, thoroughly washed with acetate buffer, and soaked in the buffer for two hours, harvested and weighed after removal of excess buffer with qualitative filter paper, and either immediately used for bioconversion runs or stored at 4ºC until use. Alternatively, immobilized biocatalyst particles were prepared by extruding drop-wise the LentiKat® liquid containing inulinase into stirred 150 ml of PEG 600. After a 2-hour period, the hemispherical capsules formed were harvested, thoroughly washed with acetate buffer, weighed after removal of excess buffer with qualitative filter paper, and either immediately used for bioconversion runs or stored at 4ºC until use. Immobilization yield was determined as the ratio between the specific activity of immobilized inulinase and that of the soluble inulinase, in a 30 minutes run. Runs were performed in 1.5 ml screw-capped magnetically stirred (500 rpm) reactors, filled with 1.0 ml of 100 mM acetate buffer (pH 4.5), containing 5.0% (w/v) of inulin.

Determination of temperature and pH profiles and of kinetic parameters

Experiments were performed at the intended pH (4–6) and temperature (40–65ºC), in inulin (5.0 % w/v, unless stated otherwise) dissolved in 1 ml of acetate buffer (100 mM), containing 50 mg of immobilized inulinase or 20 μl of a 40-fold diluted preparation of free inulinase. Runs were performed in 1.5 ml screw caped vessels and agitation (500 rpm) was promoted by magnetic stirring. Samples (10 μl) were taken after 30 minutes and immediately assayed for reducing sugars. All runs were performed in triplicates, at least. Kinetic parameters were determined using the commercial software Leonora (Cornish-Bowden,1995)

Repeated batch hydrolysis

Reactions were performed in 1.5 ml screw-capped magnetically stirred (500 rpm) reactors at 50ºC or 55ºC, in 1.0 ml of 100 mM acetate buffer (pH 4.5), containing 5.0% (w/v) of inulin and 50 mg of immobilized inulinase. Throughout each cycle (24-hours run), 10 μl samples were collected and assayed for reducing sugars. After each cycle the immobilized biocatalyst was harvested, thoroughly washed with acetate buffer and used for the next run. All runs were performed in triplicates, at least.

Analytical methods

Quantification of reducing sugars was performed by the DNS method (Miller, 1959). Quantification of protein was performed by the BCA method (Smith et al., 1985) using a commercial kit from Pierce. Particles of immobilized biocatalyst were dissolved in distilled water heated at 70ºC, prior to protein quantification. Liquid supernatants resulting form the immobilization procedures were also assayed for protein levels. The standard deviation from these determinations did not exceed 8%, except if stated otherwise.

3. Results and discussion

Depending on the nature of the procedure for the formation of the production of the PVA-encapsulated inulinase, different shapes were obtained (Figure 1).

Figure 1. Typical shapes of PVA capsules obtained according to the standard Genialab methodology to yield lens-shaped particles, Lentikats® (a); or following extrusion into PEG 600, to yield hemispherical particles (b).

Lentikats® allowed slightly higher enzyme loading and activity retention upon immobilization when compared to hemispherical beads, but the differences are not significant (Table 1). No traces of protein were observed in the supernatants resulting from the immobilization procedures, hence the difference in enzyme loading may be ascribed to the differences in overall weight of the particles obtained. Given the mild methodology used for immobilization, immobilization yields are most likely affected by diffusion limitations. Still, roughly full conversion of a 5.0 % (w/v) solution of inulin is obtained after a 24-hour biotransformation period, as reflected by the final product concentration, which is similar to the result obtained with the free enzyme, and clearly highlights the potential of this approach.

Table 1. Immobilization of inulinase in Lentikat®-liquid based matrices.

Immobilized biocatalyst	**Relative mass of the capsules (%)**	**Enzyme loading (mg $g^{-1}_{support}$)**	**Immobilizaton yield (%)**	**Final product concentration (g l^{-1})[a]**
Lentikats®	80	0.20 ± 0.05	34 ± 5	46 ± 3
Hemispherical capsules	100	0.13 ± 0.02	37 ± 4	47 ± 2
Free enzyme	-	-	-	49± 4

[a] Determined after a 24-hour biotransformation run using a 5.0 % w/v inulin solution in 100 mM acetate buffer, pH 4.5 and using similar amount of enzyme.

The activity retention upon immobilization in PVA matrices compares favorably or at least matches data from other authors for immobilization of inulinase in gelatin (Bajpai and Margaritis, 1985), casein (Kochhar et al., 1998), activated charcoal, porous silica beads, gelatin and gelatin-citrate (Paula et al., 2007), alginate and Dowex (Gill et al., 2006).

Effect of pH and temperature in enzyme activity

The influence of pH on the initial activity of free and immobilized inulinase was evaluated in the pH range 4.0–6.0 at 50 ºC (Figure 2a).

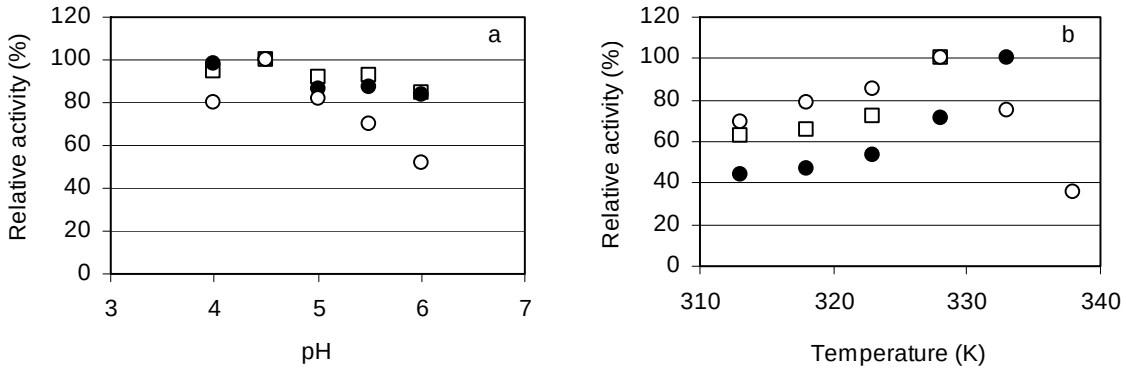

Figure 2. pH (a) and temperature (b) profiles of free inulinase (open dots), inulinase immobilized in Lentikats® (open squares) and inulinase immobilized in hemispherical particles (closed dots). Reactions were performed in 100 mM acetate buffer containing 5.0 % (w/v) of inulin, at 50ºC (a) and pH 4.5 (b).

Both free and immobilized forms of the enzyme show an optimum pH for catalytic activity at 4.5. A much broader-shaped curve was observed for the two immobilized forms of the biocatalyst, when compared to the free form, particularly in the more acidic range. This can be advantageous, for operation at lower pH values reduces the risk of microbial contamination. A broadened pH range upon immobilization was also reported for inulinase immobilization in Amberlite (Rocha et al., 2006), but was not observed for immobilization in DEAE-Sephacel or in QAE-Sephadex (Gill et al., 2006). This effect was also reported for invertase immobilization in Lentikats®, and was tentatively ascribed to secondary interactions between the polymer and the enzyme and polymer matrix throughout the immobilization process (Rebros et al., 2007).

The free inulinase displayed the maximum activity at 55 ºC. The activity of the inulinase immobilized in Lentikats® steadily increased up to 55 ºC, but above this temperature the PVA-based matrix was shown to be unstable and tended to melt, a feature that effectively took place almost immediately once the lens-shaped particles were incubated at 60 ºC. Such behavior, that clearly prevents the useful application of Lentikats® above 55 ºC, was previously reported by Rebros and co-workers (2007), while evaluating the use of immobilized invertase for sucrose hydrolysis. Hemispherical shaped particles displayed slightly enhanced mechanical stability, for temperature activity profile could be evaluated up to 60ºC, with biocatalytic activity also consistently increasing with temperature. Above 60 ºC, however the trend towards melting was also observed, hence 60 ºC was determined as the temperature for maximum activity for the latter immobilized biocatalyst. Particle formation through extrusion into PEG seems thus to slightly enhance mechanical stability at the higher temperatures tested, and therefore increase the optimum temperature for immobilized inulinase activity, when matched to the free form.

Effect of immobilization in kinetic parameters

The trials for the evaluation of the kinetic constants for the Michaelis-Menten type kinetics of inulin enzymatic hydrolysis (Rocha et al., 2006), were performed at pH 4.5 and 50 ºC. Kinetic constants were determined from experimental data using Leonora software (Cornish-Bowden, 1995). The K_M for both forms of the immobilized enzyme was roughly 2-fold higher than that of the free inulinase (Table 2). Such increase can be most likely ascribed to the impaired accessibility of the bulky inulin molecule to the active site of the immobilized enzyme due to the diffusion barrier created by the matrix. Although the thin nature of the lenticular particles would be likely to lower diffusion hindrances, when compared to hemispherical particles, that effect was not significantly noticeable, given the similarity of the data. An increase in K_M upon immobilization by entrapment in gelatin (Bajpai and Margaritis,

1985) or adsorption in porous supports (Gupta et al., 1992) has also been reported. Immobilization also affected V_{max} was also affected by immobilization, a roughly 4-fold decease was observed, irrespective of the immobilization strategy, as compared to the free enzyme (Table 2).

Table 2. Kinetics constants obtained for inulin hydrolysis with free and immobilized inulinase.

Biocatalyst	**K_M (g l^{-1})**	**V_{max} ($g_{fructose}$ g^{-1}_{enzyme} s^{-1})**
Free enzyme	26 ± 3	2.7± 0.1
Lentikats®	46 ± 8	1.1 ± 0.2
Hemispherical	53 ± 5	0.71 ± 0.02

Biocatalyst reuse

The feasibility of the application of an immobilized enzyme system in a large scale process clearly depends on its operational stability. In order to evaluate this key parameter, repeated batch hydrolysis runs were performed at 50 ºC and 55 ºC, using both immobilized biocatalysts (Figure 3). Reuse of the immobilized biocatalyst at 55 ºC proved unfeasible due to mechanical instability of the supports. This effect was also somehow noticed in Lentikats® at 50 ºC, which seemed furthermore relatively sensitive to stress from magnetic stirring. Hemispherical beads were successfully used at 50 ºC throughout 20 cycles, displaying a final decrease in the relative product yield of roughly 20%.

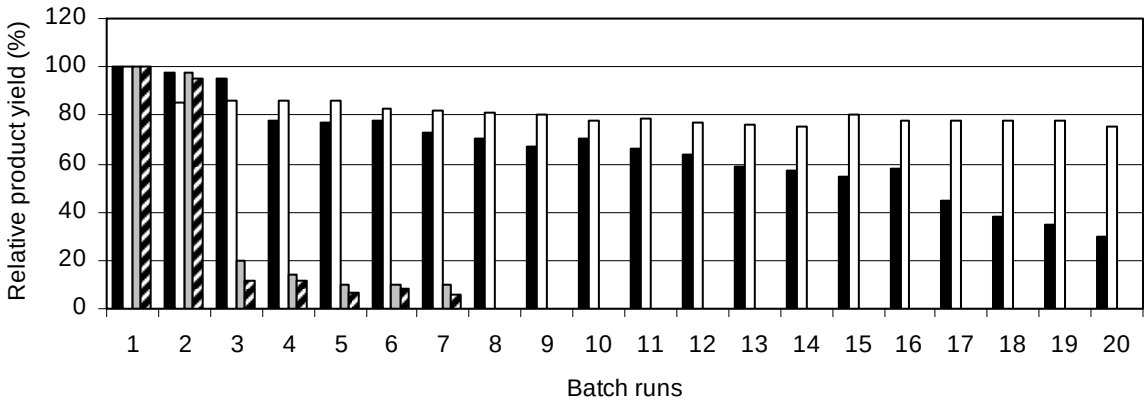

Figure 3. Effect on the final product yield of the repeated use of inulinase immobilized in Lentikats® (closed and grey bars) and in hemispherical beads (open and stripped bars), for the hydrolysis of a 5% (w/v) inulin solution. Batch runs (24 h) were performed at 50 ºC (closed and open bars) and 55 ºC (grey and stripped bars), at pH 4.5. Final fructose concentration in the first cycle was 50 g l^{-1}.Standard deviation did not exceed 10%.

4. Conclusions

Inulinase was effectively immobilized polyvinyl alcohol particles, either as LentiKats® or in hemispherical beads obtained through extrusion of LentiKat® liquid into PEG 600. Immobilization broadened the pH-activity profile paving the way for operation under relatively acidic conditions. The activity of free and LentiKats® immobilized enzyme reached a maximum at 55 ºC, which was shifted to 60 ºC when hemispherical beads were used. Still in

both immobilized preparations a significant decay in mechanical strength was observed above 55ºC, which limits to 50 ºC their application in long term operation. Diffusion limitations were observed as a result of entrapment. Hemispherical beads were successfully used throughout 20 consecutive batch runs with no apparent mechanical changes in the matrix and no significant decrease in the final product yield, which highlight the potential of inulinase immobilized in PVA-based particles obtained through extrusion into PEG as a suitable biocatalyst for application in large scale processes for fructose production through inulin hydrolysis.

Topic: Integration of life sciences & engineering

Abstract

Biodiesel production from acids oils is considered as a step up of recycling waste oil and has a positive environmental impact. In this study the biodiesel production from macauba high acid oil using *C. antarctica* B lipase (CALB) immobilized in green coconut fiber was investigated. The results showed that the conversion rate of a reaction catalyzed by CALB immobilized in coconut was similar to Novozyme 435. Maximum conversion (82.91%) was obtained at 50ºC, amount of catalyst of 10% w/w of oil and macauba acid oil: ethanol ratio of 3:1 w/w. The viscosity of this biodiesel from macauba acid oil (2.75 cSt, at 40ºC) is smaller than reported values in the literature.

1 Introduction

Biodiesel is defined by American Society for Testing and Materials (ASTM) as monoalkyl esters of long chain fatty acids derived from a renewable lipid feedstock, such as vegetable oil or animal fat. It is a renewable and sustainable substitute of the diesel fuel traditionally obtained from petroleum (MARCHETTI *et al*., 2008). Actually, one of the biggest disadvantages of the use of biodiesel is its high cost in comparison with petroleum-based fuel. Feedstock oil is responsible for 60-75% of the cost (TAMALAMPUDI *et al*., 2008). Thus, to provide biodiesel at a reasonable price, not only refined vegetable oils but mainly crude, waste materials and by-products should be used.

Brazil has a vegetable rich variation that can be used as oil source, as castor-bean, palm, macauba, sunflower, babassu, soy, and others. From these vegetables, macauba (*Acrocomia aculeata*) has potential to produce up to 5 ton of palmitic oil and 1.4 ton of lauric oil giving a total productivity of 6.4 ton of oil/ha (CLEMENTE *et al*., 2005). This feature highlights this palm tree as a good source of oil. Another characteristic of this fruit is that its oil presents high content of free fatty acids few weeks after raw fruit harvest. This occurs due to the high content of unsaturated fatty acids and the endogenous enzymes in the macauba pulp.

In biodiesel production studies, several researches have been attempt to acid oils. Biodiesel production from acids oils is considered as a step up of recycling waste oil and has a positive environmental impact. However, using alkaline catalyst, there is a significant drop in the ester conversion when free fatty acids are beyond 2% (SHARMA *et al*., 2008). Thus, to apply chemical catalysis is necessary to perform a pretreatment in order to reduce the free fatty acids. In this case, use of immobilized lipases for biodiesel production eliminates the disadvantages of the homogeneous process by producing of very high purity product without pretreatment and with less or no downstream operations.

Therefore, the aim of this study was to investigate the kinetic of enzymatic esterification and transesterification reaction of macauba high acid oil for biodiesel production using *C. antarctica* B lipase immobilized in green coconut fiber. In this work, the biodiesel fuel was produced by the enzyme-catalyzed esterification and transesterification from high acid value macauba oil and ethanol. The selected routes are able to use less expensive feedstocks that cannot be converted to biodiesel by conventional methods which use strong base, such as sodium hydroxide.

2 Material and Methods

Raw-material: Macauba acid oil utilized in this study was purchased from rural producers at Minas Gerais State, Brazil. Free fatty acids in the oil were determined by AOCS Official Method. The sample was diluted in a neutralized solvent, followed by titration with a standard NaOH solution (0.1N), in the presence of phenolphthalein as indicator (AOCS, 2004).

Immobilized biocatalyst production: CALB was immobilized by adsorption on green coconut fiber, at room temperature, through the enzyme - support contact for 2 h. For each gram of dry support, 10 mL of lipase solution (1000 U/L), in 25 mM sodium phosphate buffer, were used. After immobilization, the biocatalyst was separated by filtration, rinsed with phosphate buffer and dried at vacuum for 10 min.

Biodiesel synthesis: A batch small-scale reaction was performed in a thermostatized bath from a mixture of macauba acid oil and ethanol (3:1 w/w) using lipase type B from *C. antarctica* immobilized in coconut fiber as catalyst. The enzyme was added in the proportion of 10% to the oil weight and the alcoholysis was carried at 35^{o}C and 30 rpm during 96h (FUKUDA *et al*., 2001). The mixture was filtered under vacuum. The enzyme was recovered in filter paper and glycerin was easily separated by gravity. Experiments, carried under same experimental conditions, were performed with a commercial immobilized lipase (Novozym 435) to compare with the coconut immobilized lipase performance.

Additionally, the hydroesterification using the macauba acid oil was carried out in two steps for comparison purposes: hydrolysis of the oil at 300^{o}C and 1000 psi, followed by acid-catalyzed methanolysis performed at 190^{o}C and 500 psi using niobic acid (NB-340 CBMM) as catalyst at concentration of 10 wt% relative to FFA

Yield: The conversion efficiency to methyl esters was accomplished by colorimetric method at intervals of 24 h. Determination of free glycerol in biodiesel was performed measuring the absorbance at 500 nm (ARANDA and ANTUNES, 2004).

Statistical analysis: A 2^3 complete factorial design was adopted to evaluate the effects of three operational parameters on biodiesel conversion from *C. antarctica* immobilized in coconut fiber: catalyst concentration in relation to oil mass (5-10 %), temperature (35-50^{o}C) and oil:ethanol weight ratio (3:1-6:1). Those selected levels were based on preliminary experiments. The standard deviation was evaluated from triplicate experiments carried out at the center-point and the experiments were carried out in a randomized order. The experimental data obtained were analyzed by the response surface regression procedure to fit a non linear first order model as follows: $Y = \lambda_0 + \sum \lambda_i X_i + \sum \lambda_{ij} X_{ij}$ (1)

where Y is the predicted response variable, λ_o, λ_i, λ_{ij} are regression coefficients of the model, and X_i, X_j represent the independent variables in the form of coded values. Statistica software version 7.0 was used for variance analysis.

Rheology: The biodiesel viscosity was determined in a cone-plate rheometer (Brookfield Ultra/DVD III). The variation of kinematic viscosity (η) with temperature was represented by equation: $\eta = e^{(A+B/T+C/T^2)}$ (2)

3 Results

The macauba acid oil presented 27 to 30% of free fatty acids, expressed as oleic acid. This oil have higher free fatty acid levels: 2 and 12 fold compared to jatropha and karanja oil for example (SHARMA *et al.*, 2008). Viscosity is another important property of vegetable oil and biodiesel. The average viscosity of vegetable oil is in ranger of 23.2 to 53.0 cSt at ~40ºC (DEMIRBAS, 2008). For macauba acid oil, the viscosity value is 26.82 cSt at 40ºC. Another characteristic is the molecular weight of waste oil, 858.7, which was calculated from fatty acid composition of macauba oil (FREITAS *et al*., 2008).

A preliminar test was realized to compare the effect of reaction time on the conversion of macauba oil in fatty acids ethyl esters when catalyzed by CALB immobilized in coconut fiber or by Novozyme 435 (Figure 1). The reaction conditions were T=35ºC, amount of catalyst of 10% w/w of oil and macauba acid oil: ethanol ratio of 3:1 w/w. The lipase immobilized in coconut fiber reached biodiesel conversion of 53±1.61% after 24 h and for reaction catalyzed by Novozyme 435, after 24 h, the conversion was 52.33±0.58%. The maximum conversion (82±3.0 %) was reached after 72 h in a reaction catalyzed by Novozyme 435, however this value is only slightly superior at CALB immobilized in coconut fiber. In this way, we selected the CALB immobilized in coconut fiber as catalysis for operational parameters analysis on biodiesel conversion.

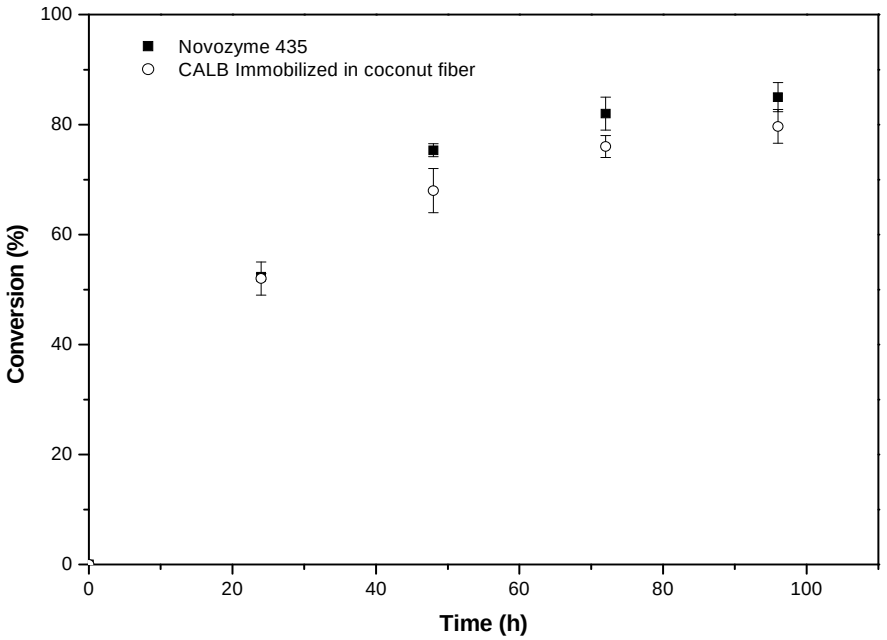

Figure 1. Kinetic of conversion of macauba oil in fatty acids ethyl esters using CALB immobilized in coconut fiber and commercial enzyme (Novozyme 435).

The results of the 2^3 complete factorial design are shown in Table 1. Maximum conversion (82.91%) was obtained at 50ºC, amount of catalyst of 10% w/w of oil and macauba acid oil: ethanol ratio of 3:1 (w/w). This value is comparable to the conversion obtained when the reaction was catalyzed by Novozyme 435 (82±3.0 %), after 72 h (Figure 1). For researches where ethanol was the nucleophile, after 24h, maximum conversion for Novozyme 435 was 86 % (HERNÁNDEZ-MARTÍN and OTERO, 2008), a value near to obtained in this study for CALB immobilized in coconut fiber.

The results of experimental design were analyzed via multiple regressions. The coefficients of a full model were evaluated via regression analysis and tested for significance, leading to the best model fiited. This showed that only the linear coefficients (X_1, X_2, X_3) were

significant. The ANOVA analysis for response surface, considering only the significant coefficients, is provided in Table 2.

Table 1 - 2^3 complete factorial design matrix and the responses of the dependent variable

The final estimative response model equation by which the conversion rate of macauba oil to biodiesel was estimated was as follows: $Y = 66.95 + 8.97X_1 + 10.02X_2 - 6.52X_3$ (3).

From this model, we can to conclude that, for the experimental range analyzed, the enzyme concentration was the most relevant parameter affecting the transesterification, followed by temperature and oil:ethanol ratio. As expected, this factor has a positive influence, but the enzyme cost should be considered as the main limitation to increase enzyme concentration in the process.

Using the conditions where maximum conversion was reached, 50ºC, amount of catalyst of 10% w/w of oil and macauba acid oil: ethanol ratio of 3:1 (w/w), lipase-based biodiesel was used in some product analyses. First, the variation of kinematic viscosity (η) with temperature for lipase-based biodiesel and macauba acid oil were evaluated (Figure 2). The constants (A, B, C) and the regression coefficients (R^2) for each regression shown in Figure 2 are presented in Table 3. The viscosity of the biodiesel obtained from macauba acid oil (2.75 cSt, at 40ºC) is in accordance with biodiesel standards outlined in EN 590 and it is smaller than reported values in the literaturature (2.83 to 5.12 cSt, at 40^{o}C) (DEMIRBAS, 2008).

Although the transesterification time using lipase is higher, bioconversion appears as a cleaner technology to biodiesel production. Furthermore, glycerin can be easily recovered, biodiesel presented lower viscosity and better quality due to very low temperature of enzymatic reaction (35^{o}C).

In parallel, the hydroesterification process with niobic acid has been studied for a comparison with biocatalyzed reaction. The hydroesterification processes reached 78±2.0 % and 22±0.5% of conversion in a very smaller reaction time (60 minutes) for systems with methanol and ethanol, respectively (Figure 3). And regarding the lipase-based biodiesel the viscosity decrease of 5.4 cSt at 20°C to 2.2 cSt at 40°C (Ea/R = 4108 K) while to hidroesterification-based biodiesel the viscosity decrease of 10.6 cSt at 20°C to 5.34 cSt at 40°C (Ea/R = 3117 K).

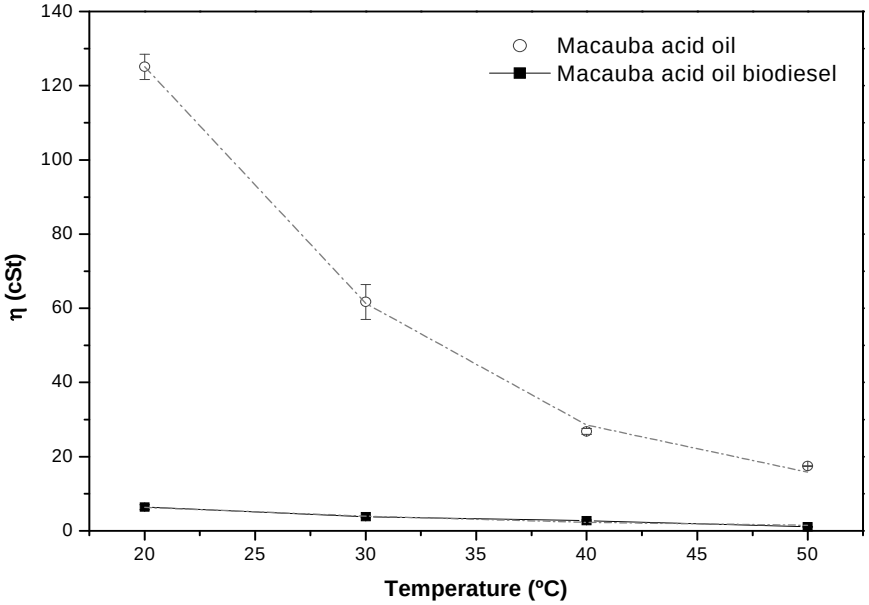

Figure 2. Variation of macauba acid oil and biodiesel kinematic viscosity with temperature.

Table 3 – Regression parameters for viscosity

Fuel type	Regression equation $\eta = e^{(A+B/T+C/T^2)}$			
	A	**B**	**C**	**R^2**
Macauba acid oil	-0.57232	205.81453	-1955.5515	0.9992
Macauba acid oil biodiesel	-2.03205	150.96777	-1467.13455	0.97319

Conclusions

Candida antarctica B lipase immobilized in coconut fiber was found to be an active enzyme catalyzing the conversion of high acid value waste oil to biodiesel. For only one cycle, the conversion rate of a reaction catalyzed by CALB immobilized in coconut was similar to Novozyme 435. And, however studies of hydroesterification had shown smaller reaction time, easier separation and purification steps and better viscosity value were observed using enzymatic process. These results are an indicative that CALB immobilized in coconut fiber can be a cheap alternative catalyst to biodiesel production. To confirm this, more studies analyzing CALB immobilized in coconut operational stability, biodiesel characteristics and others are being performed.

Topic: Sustainable process-product development through green chemistry

Introduction

The synthesis of enantiomeric pure chiral compounds, became one of the most important fields of chemistry investigation due to their significance in the pharmaceutical industry. Chiral secondary alcohols are usually used as synthetic intermediates or chiral auxiliaries in the synthesis of different drugs (Stecher & Faber, 1997). The demand for attainment one or, in certain cases, both enantiomers alcohols with pharmacological value, lead to the development of strategies to access such chiral compounds, namely enzymatic resolution (Wang *et al.*, 1988), asymmetric hydrogenation of ketones (Noyori *et al.*, 1995), Corey-Bakshi-Shibata borane reduction (Corey *et al.*, 1987), kinetic resolution of epoxides (Tokunaga *et al.*, 1997), ketone reduction (Goldberg *et al.*, 2007) and fermentation (Suzuki *et al.*, 1996).

Several different techniques have been developed to achieve the resolution of enantiomers. Some of these techniques take advantage of the chemical or physical properties differences in each enantiomer, such as crystallization, chromatography, distillation, membranes technology (Maier *et al.*, 2001).

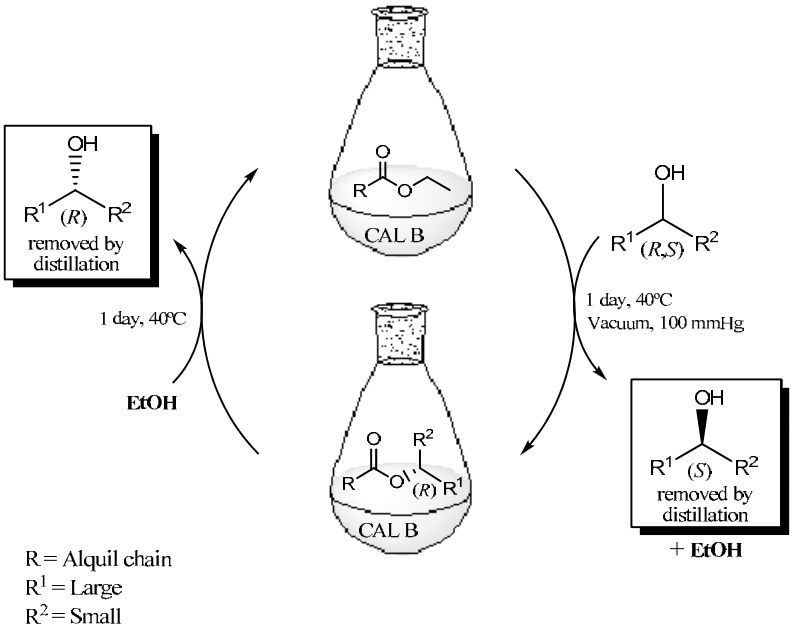
Enzymatic kinetic resolution of racemic alcohols is a well-established method and often the unique and/or most practical route for the preparation of enantiomerically enriched precursors (Ghanem, 2007; Patel, 2001). The enzymes present real advantages in view of the fact that they catalyse reactions under mild conditions with high enantio- or diasteroselectivity, high efficiency and offer the possibility of working with organic solvents (Kazandjian & Klibanov, 1985), supercritical fluids or ionic liquids (Rasalkar *et al.*, 2004). On the other hand, some limitations are observed, specifically the need of large excess of acylating agent and in what concern to the separation step. The chromatography techniques usually used on the separation of enantiomers are a drawback at large scale. More elegant methods of separation have been report to improve the separation of the alcohol from the acylating agent, such as, by using fluorous solvent (Luo *et al.*, 2002), ionic liquids (Lourenco & Afonso, 2007), membrane or PEG (Nogawa et al., 2006).

The selection of the acylating group is an important issue for the separation and to achieve irreversible esterification. The utility of vinyl esters and isopropenyl esters as acylating reagents in this enzymatic reactions was reported since 1987, but present some restrictions like formation of side products (Hanefeld, 2003). New acylating agents are being developed in order to oppose those limitations, namely succinic anhydride (Gutman *et al.*, 1993; Vaidyanathan *et al.*, 2007) and carbonates (Pozo *et al.*, 1992).

The production of enantiomerical enriched secondary alcohols at large (Negishi *et al.*, 1997) or lab (Irimescu *et al.*, 2003) scale by enzymatic esterification or transesterification using

ester from fatty acids was claimed. These reactions were carried out without organic solvents and continuous removal of water or volatile alcohol under vacuum.

Herein we present the progress achieved for irreversible enzymatic kinetic resolution of secondary alcohols in the presence of fatty esters without solvents under vacuum; utilization of the same enzyme for recover of the other enantiomer by transesterification; and application of low pressure distillation as a green separation technique.



Scheme 1 - Enzymatic transesterification for the resolution of *rac-sec*-alcohols

Results and discussion

On course of previously work developed in this laboratory, where ionic liquids and ionic acylating agents were applied, it was reported a simple, robust, reliable, reusable and efficient preparative methodology for the one pot resolution-separation of *sec*-alcohols based on the enzymatic resolution with CAL B as biocatalyst. It was also demonstrated by this strategy the possibility to separate both enantiomers only by enzymatic resolution and extraction, without need or chromatographic separations techniques.

The acylating agent and the alcohol for this study were selected based on their chemical and physical properties. The fatty esters are stable liquid compounds, which are easily prepared in high yield and high purity, that present good properties as a solvent and acylating agent, avoiding the use of organic solvents. The alcohol tested was the 1-phenylethanol, a compound formed by a bulky phenyl and a small methyl group that can be used as model in the studies of enantioselective catalysts for alcohol conversion.

The conditions used were optimized with the aim of control and shift to products formation. In this way the reaction was performed under vacuum (100 mmHg) during 24 hours at 40ºC. Under these conditions the evaporation of the alcohol is minimal and we obtained better conversions.

From the results obtained (Table 1) we can observe that the efficiency of the enzyme is retained for the two cycles since minimal erosion of yield and enantioselectivity was observed for each transesterification step. Further, the lose of 3-7% yield in each step is due to product lost during the distillation process.

Table 1. Results for enzymatic resolution of (*rac*)-1-Phenylethanol following the method described on scheme 1.

Cycle	*(S)*-1-phenylethanol		*(R)*-1-phenylethanol	
	Yield (%)	ee (%)[a]	Yield (%)	ee (%)[a]
1	47	89	44	86
2	43	87	44	80

[a] enantiomer excess analyzed by GC

Conclusions

A more sustainable method for efficient enantiomeric kinetic resolution and enantiomer separation of secondary alcohols is demonstrated based on: 1) use of fatty esters as acylating agents, by removal of the unreacted enantiomer alcohol by distillation, while the other enantiomer stay in the form of less volatile fatty ester; 2) second enzymatic reaction to generate the other enantiomer and the acycling agent ready for the next cycle.

Experimental

General procedure for enzymatic kinetic resolution and separation of sec-alcohols: CALB (Novozym 435; 500 mg) and racemic 1-phenylethanol (10.35 mmol) were added to a stirred ethyl myristate (10.35 mmol). The reaction mixture was stirred for 24 hours under reduced pressure (100 mmHg) at 40ºC in a thermostatic bath. After this time, the reaction mixture was filtrated and the enzyme washed with hexane (3 x 15 mL). The solvent was then evaporated and destilated under reduced pressure (1mmHg, 60ºC) to give the *(S)*-1-phenylethanol.

The enzyme was dried under reduced pressure (20 mmHg) for 2 h.

After distillation, ethanol (2.5 equiv) and the recovered enzyme were added and the mixture was stirred for 24 hours at 40ºC in a thermostatic bath.

Then, the reaction mixture was filtrated again and the enzyme washed with hexane (3 x 15 mL). The solvent was then evaporated and destilated under reduced pressure (1mmHg, 60ºC) to give the *(R)*-1-Phenylethanol.

Reuse experiment: The enzyme was dried under reduced pressure (20 mmHg) for 2 h and added to recovered ethyl myristate, then more racemic 1-phenylethanol (10.35 mmol) was added to the mixture, and the reaction was performed as described above.

The GC analysis of 1-phenylethanol was performed using Trace Focus Unicam, FID detection, using capillary column astec chiraldex^{TM} G-TA (30m $\times$0.25mm $\times$ 0.12µm). t_R (*S*) = 12.78 min.; t_R (*R*)-25= 13.45 min.

Enhanced Production of Recombinant Staphylokinase: An Experimental Design Approach

Arshad Jawed, K. L. Dikshit, Debendra K. Sahoo*
IMTECH - Institute for Microbial Technology, Sector 39A, Chandigarh, INDIA, 160 036

Keywords: Staphylokinase, Response surface methodology, Central composite design, Optimization, *Escherichia coli*
Topic: Integration of life sciences & engineering.

Abstract

Aiming at large-scale production of staphylokianse we cloned and intracellularly expressed staphylokinase in plasmid pET-9b using *Escherichia coli* as host in soluble form. Initial optimization studies, carried out for increasing SAK expression using defined medium resulted in a cell concentration of 1.15 g DCW/L and staphylokinase production of 84.5 mg SAK/L. Further optimization was carried out by using statistical methods, namely Response Surface Methodology (RSM). RSM was employed with 4 variables at 5 levels of concentrations using Central Composite Design (CCD), with glucose, KH_2PO_4, $(NH_4)_2HPO_4$ and various organic nitrogen sources in separate experiments and also in combination by D-optimal design. Optimized medium resulted in cell concentration of 1.97 g DCW/L and staphylokinase expression level of 83.0 mg SAK/g DCW corresponding to 163.86 mg SAK/L. The results obtained were validated at fermentation of scale of 5 L, with final cell concentration of 5.8 g DCW/L and staphylokinase production exceeding 415 mg SAK/L in batch mode. Fed-batch fermentation strategy with nutrient (substate) feeding resulted in 24.4 g DCW/L with 1290 mg of SAK/L at 5L and the process was scaled up and validated at 20L scale.

1. Introduction

Thrombolytic therapies aim at early dissolution of the blood clot that causes occlusive thrombosis and results in heart attack. The 15.5 kDa bacterial protein staphylokinase (SAK) isolated from *Staphylococcus aureus* is one such molecule that forms a stochiometric protein-protein complex with plasmin (-ogen) in the plasma millieu and the complex thus formed is capable of dissolving the blood clots (Collen and Lijnen, 1991). The SAK-plasmin(ogen) complex is fibrin specific and is strongly inhibited by α_2-antiplasmin and recycles staphylokinase in its active form (Collen,1998; Lijnen *et al*. 1991; Silence *et al*. 1993).

Owing to the market potential, we aimed for development of a process for production of staphylokinase, especially with a significantly increased product titer. Process development cannot be generalized for every protein or expression sytem or a combination there off as the requirements for maximum growth and productivity are highly case specific and are unique in terms of promoter systems, host-vector interaction, amino acid sequences and the characteristics of the recombinant protein (Shin *et al*. 1997). The effect of parameters such as medium composition, nutrient concentration and availability, dissolved oxygen concentration, specific growth rate, concentration of inducer and antibiotic (selection pressure), plasmid stability, formation of inhibitory by-products etc., varies from case to case and have to be studied in detail for each process and expression host (Lee, 1996).

2. Materials and Methods

2.1 Bacterial strain and plasmid

The strain used was *Escherichia coli* BL 21, transformed with plasmid pET 9b, containing gene for staphylokinase, that was placed downstream of the T7 RNA promoter regulated by the control of *lac* promoter in pET-series expression vector. A kanamycin resistance gene present in the plasmid acts as a selection marker. The culture was maintained in glycerol stocks at –70 ^{0}C in an ultra-low freezer.

2.2 Culture medium

The staphylokinase production medium for initial screening included LB medium, a defined (synthetic) medium and a defined medium supplemented with yeast extract (semi-synthetic). The defined (synthetic) medium consists of glucose 10 gL^{-1} (carbon source), KH_2PO_4, 1.33 gL^{-1}, $(NH_4)_2HPO_4$, 4 gL^{-1}, $MgSO_4.7H_2O$, 0.40 gL^{-1} and trace metal solution. The staphylokinase production medium consisted of varied concentrations of carbon source (Glucose), nitrogen source (yeast extract / tryptone / peptone), KH_2PO_4), $(NH_4)_2HPO_4$ and $MgSO_4.7H_2O$, 0.04 gL^{-1} and trace metals as per experimental plan. The initial pH of the medium was adjusted to 6.8 by 1N NaOH or 1N HCl.

2.3 Inoculum preparation and culture conditions

LB agar plates (containing Kanamycin, 30 µg/ml) streaked with a loopful of culture from frozen glycerol stock (kept at -70^{O}C) were incubated overnight at 37 ^{0}C. A single isolated colony, picked from this plate, was used to inoculate 10 ml LB medium (as pre-inoculum) and incubated in a rotary shaker at 37 ^{0}C at 200 rpm for 8 h. It was used to inoculate 90 ml of LB medium taken in 500 ml flask and the flask was incubated in a rotary shaker at 200 rpm and 37 ^{0}C for 8 h to be used latter as inoculum for the production medium. After inoculation, the flasks were added with kanamycin (30 µg/ml) to maintain plasmid stability and after 4 h of incubation at 37 ^{0}C and 200 rpm, the culture was induced with Iso-Propyl-Thio-Galactoside (IPTG), 0.5 mM for staphylokinase expression.

2.4 Analytical methods

Samples were taken from the culture broth after 4 h of induction with IPTG, and centrifuged at 10,000 rpm for 15 minutes. The settled cell mass from one tube was dissolved in sterile saline and was used to estimate cell growth by measuring cell density at 600 nm using a spectrophotometer. (One absorbance unit corresponds to 0.46 gDCW OD^{-1} L^{-1}). The cells settled in other tubes were lysed to release intracellular proteins, using multiple sample buffer (containing urea and β-mercaptoethanol). The lysate was directly loaded onto 12 % SDS-Poly-acrylamide gel. The protein concentration was obtained by densitometry with Bovine serum albumin (BSA) as standard on a gel documentation system using GENE SNAP and GENE TOOLS (Syngene Inc., USA).

2.5 *Design of experiments*

Response surface methodology, a powerful tool for understanding complex processes and for describing factor interactions in multi-factor systems, has been used for designing the experiments. In our study, a fractional factorial design, using Design Expert Software (Stat Ease Inc., Minneapolis. U.S.) was employed. The optimum levels for growth and staphylokinase production by the recombinant strain, with respect to carbon source, nitrogen source and phosphates were obtained by response surface methodology. Using response surface methodology, the relationship among the variables, i.e. Carbon source, Nitrogen source, KH_2PO_4, $(NH_4)_2HPO_4$, were expressed mathematically in the form of a polynomial model, which gave the response as a function of relevant variables. The present work was based on Central

Composite Design (CCD) utilized to obtain the experimental data, which would fit an empirical second order polynomial model representing the response surfaces over a relatively broad range of parameters.

A second order RSM design with 5 levels CCD was used to explore the effect of various medium ingredients on growth and formation of product. Each factor was studied at five different levels (-2, -1, 0, 1, 2). The test variables chosen in this study were KH_2PO_4, $(NH_4)_2HPO_4$, glucose and nitrogen sources (yeast extract / tryptone / peptone) in separate experiments. After obtaining the optimum results, the effect of a combination of the three nitrogen sources was checked by D-optimal design. The optimal concentrations of the critical medium components were obtained by solving the regression equation and also by analyzing the response surface contour plots.

3. Results and Discussion

Luria-Bertini is one of the widely used undefined mediums for production of recombinant proteins. The medium suffers with the major drawback of quality and varying nutrient contents, leading to high batch-to-batch variation and less reproducibility at fermentations scale (Lee, 1996) and has a number of limitations for use in fed-batch fermentation. On the other hand, the synthetic medium provides better controllability with respect to nutrients and other parameters, but may result in lower product formation. So, many times synthetic medium needs supplementation with complex complex organic nitrogen sources to yield better productivity.

3.1 RSM with Tryptone as nitrogen source

Central composite design (CCD) with glucose, tryptone, KH_2PO_4 and $(NH_4)_2HPO_4$ were chosen as independent variables and for each run, the experimental responses, namely cell growth and staphylokinase expression were obtained at 4 h of induction with IPTG or at 8 h of incubation. ANOVA was required to test the significance, adequacy and accuracy of the model. Emphasis was given on maximizing both the responses namely cell growth and staphylokinase expression. The statistical analysis of the data showed that the level of significance for the model was above 95 % (with p-value <0.001). A *p*-value less than 0.05 indicate the adequacy of the model and less than 0.1 indicates the adequacy of the interaction.

By applying multiple regression analysis on experimental data, the experimental results fitted into quadratic model, with R^2 value of 0.98, for *Escherichia coli* cell growth and R^2 value of 0.99 for staphylokinase production. Both the models showed high value of regression coefficient and it was also suggested that the second order polynomial equation was accurate and capable of representing the model selected within the experimental domain. A low probability value, P<0.001 was obtained for both cell growth and staphylokinase production. The components showed good interactions with *p*-value lower than 0.1 in almost all the individual and interaction terms. The mathematical regression model for growth of cells and production of staphylokinase in the form of factors in their coded terms are given in Table 1, where the terms A, B, C and D are coded values of the variables glucose, tryptone, KH_2PO_4 and $(NH_4)_2HPO_4$. The optimum values for maximum cell growth and staphylokinase production were 4.53 gDCW and 61.89 mg SAK/g DCW (Table 2). The predicted values by the program and the actual values were found to be very close to each other.

3.2 RSM with peptone as nitrogen source

In the second case peptone was used as sole organic nitrogen source in semi-synthetic medium to investigate the region of response surface in the neighborhood of the optimum, an experimental design with more than two levels of each variable is required, so that a second order approximation to the response surface can be developed. A central composite design (CCD) with glucose, peptone, KH_2PO_4 and $(NH_4)_2HPO_4$ were chosen as independent variables and the statistical analysis of the data showed that the significance level for the model was above 95 % (with p-value <0.001).

Glucose, peptone, KH_2PO_4 and $(NH_4)_2HPO_4$ were taken as variables for analysis and optimization of parameters for maximum growth and staphylokinase production. The values obtained after experiments were considered in terms of responses and were fitted into a suitable model. By applying multiple regression analysis on experimental data, the experimental results were fitted with a second order polynomial equation and R2 value of 0.99 for *Escherichia coli* cell growth and R2 value of 0.99 for staphylokinase production were obtained. Both the models showed high value of regression coefficient and it also suggested that the second order polynomial equation was accurate and capable of representing the model selected within the experimental domain. A low probability value, $P < 0.001$ was obtained for both cell growth and staphylokinase production. The mathematical regression model for cell growth and production of staphylokinase in the form of factors in their coded terms are given in Table 1, where the terms A, B, C and D are coded values of the variables glucose, peptone, KH_2PO_4 and $(NH_4)_2HPO_4$. The optimum values for maximum cell growth and staphylokinase production were 1.86 g DCW and 73.5 mg SAK/gDCW (Table 2). The predicted values by the program and the actual values were found to be very close to each other.

3.3 RSM with Yeast extract as nitrogen source

Central Composite Design experiment was set up with the four independent variables, namely glucose, yeast extract, KH_2PO_4 and $(NH_4)_2HPO_4$. The statistical analysis of the data showed that the level of significance for the model was above 95 % (with p-value <0.01).
Glucose, yeast extract, KH_2PO_4 and $(NH_4)_2HPO_4$ were taken as variables for analysis and optimization of parameters for maximum growth and staphylokinase production. The values obtained after experiments were considered in terms of responses and were fitted into a suitable model. By applying multiple regression analysis on experimental data, the experimental results were fitted with a second order polynomial equation. In this case the results were fitted into quadratic model, with R2 value of 0.99, for *Escherichia coli* cell growth and R2 value of 0.98 for staphylokinase production. Both the models showed high value of regression coefficient and it also suggested that the second order polynomial equation was accurate and capable of representing the model selected within the experimental domain. A low probability value, $P < 0.001$ was obtained for both cell growth and staphylokinase production. The mathematical regression model for cell growth and production of staphylokinase in the form of factors in their coded terms are given in Table 1, where the terms A, B, C and D correspond to the variables glucose, tryptone, KH_2PO_4 and $(NH_4)_2HPO_4$. The optimum values for maximum cell growth and staphylokinase production were 1.70 gDCW and 71.50 mgSAK/gDCW (Table 2). The predicted values by the program and the actual values were found to be very close to each other.

As indicated by the results obtained from central composite designs by running the variables glucose, KH_2PO_4, $(NH_4)_2HPO_4$ and tryptone / peptone / yeast extract separately as the sole organic nitrogen source, it could be argued that none of the nitrogen sources had a substantial advantage over the others in enhancing cell growth or staphylokinase production. Therefore, a new set of experiment with a combination of these three organic nitrogen sources to a final concentration of 1 % (w/v) was set up using D-optimal design to investigate the effect of a combination of these three organic nitrogen sources on staphylokinase expression. The parameters were used were varied each at 5 levels (-2, -1, 0, +1, +2), with a final sum (combination of all three nitrogen sources) equal to 1 % (w/v), which was constant throughout the experiment.

3.4 D-optimal design for a combination of tryptone / peptone /yeast extract

A combination all three nitrogen sources was tried using D-optimal design with the three nitrogen sources namely, tryptone, yeast extract and peptone. The three components were locked at the maximum level of 1 % (w/v) and were varied from 0 – 1 % (w/v) at 5 levels coded as (-2, -1, 0, +1 and +2). By applying the regression analysis on the experimental data obtained, the

experimental results were fitted with a second order polynomial equation. Thus a mathematical regression model for growth of cells and staphylokinase production in the form of coded variables could be easily defined (Table 1). The experimental data fitted in the quadratic model yielded R2 value of 0.98 for cell growth and R2 value of 0.90 for staphylokinase production.

The different organic nitrogen sources showed good interactions with each other for staphylokinase expression but the interaction between tryptone and yeast extract was not found to be very significant (p-value >0.1). The optimization results showed the maximum cell growth (1.974 gDCW) along with higher expression of staphylokinase (83.01 mg SAK/g DCW) when tryptone, 0.76 (% w/v) and yeast extract, 0.24 (% w/v) were taken (approximate ratio of 3:1) and validated the use of RSM as a useful tool for the optimization of recombinant protein expression in *E. coli.*

3.5 Batch and fed-batch fermentation

Batch and fed-batch fermentation runs were performed for validation of the fermentation medium obtained by RSM and D-optimal design. Cell growth was found to be 5.9 g/L of the fermentation broth with SAK expression mounting to 480 mg SAK/L of fermentation broth, while in fed-batch mode cell growth increased to 24.4 gDCW/L and SAK expression went up to 1200 mg SAK/L of fermentation broth.

4. Conclusion

The ultimate aim of any optimization process is maximization of the yield of target product and reduction of input. Our investigation showed glucose, tryptone, yeast extract, potassium di-hydrogen phosphate and di-ammonium hydrogen phosphate to have significant effect on staphylokinase expression. The optimization work resulted in the reduction in concentration of medium components and increase in staphylokinase yield under experimental conditions. This demonstrated that the statistical approach described in this work could be successfully applied for optimization of media components in case of a recombinant therapeutic protein like staphylokinase and result in the saving of material, labor and time.

Keywords: Calixarenes; Liquid-liquid protein extraction; myoglobin; biocatalysis in organic media; pseudoactivity of peroxidase
Topic: Advancing the chemical and biological engineering fundamentals.

ABSTRACT

The present work involves the use of *p-tert*-butylcalix[4,6,8]arene carboxylic acid derivatives for selective extraction of myoglobin. All three calixarenes were found to extract this haemoprotein to organic phase, exhibiting extraction parameters higher than 0.90. Myoglobin-^{t}butyl[6]CH_2COOH complex revealed pseudoactivity of peroxidase which catalysed the oxidation of seryngaldazine in the presence of hydrogen peroxide in organic medium containing chloroform. The effect of pH, protein and substrate concentrations was investigated in biocatalysis by using myoglobin-^{t}Butil[6]CH_2COOH complex. The highest specific activity of myoglobin was 1.37×10^{-1} U. mg protein^{-1} at initial pH of 6.5 in organic medium. Apparent kinetic parameters ($V'_{máx}$, K'_m, k'_{cat} e k'_{cat}/K'_m) for the pseudo-activity of peroxidase were determined in organic media for different pH values by Michaelis-Menten. Furthermore, the stability of the protein-calixarene complex was investigated for different initial pH values and $t_{1/2}$ values were obtained in the range of 3.5 – 5.2 days. Myoglobin-calixarene complex present in organic medium was recovered in fresh aqueous solutions at alkaline pH, with a recovery of pseudo-peroxidase activity of over 100 %. The results strongly suggest that the use of calixarene derivatives is an alternative technique for protein extraction and solubilisation in organic media for biocatalysis.

INTRODUCTION

Protein recognition by synthetic molecules is a highly challenging field both in academic and applied research (Ludwig, 2005). The use of calix[n]arenes has attracted an increasing interest in the last two decades as a tool for biochemical recognition and separation of biological macromolecules such as proteins (Ludwig, 2005 and Shimojo *et al.*, 2007). Calix[n]arenes are macrocyclic structures which consist of phenol rings connected by methylene bridges. These compounds consist of cup-shaped molecules which can form host-guest complex with a wide range of guest molecules by introducing several functional groups either at the upper or lower rim (Gutsche, 1995).

Recently, Oshima *et al.* (2002 and 2005), have reported that a calix[6]arene carboxylic acid derivative (^{t}Oct[6]CH_2COOH) exhibited high affinity for cationic proteins such as cytochrome *c* by promoting its extraction in organic media. Besides the extraction of cytochrome c to organic phase by using such calixarenes, they observed pseudoactivity of peroxidase in organic solvents. Biocatalysis in non-conventional media is an important field in enzyme engineering

[1]* Corresponding author. E-mail: akarmali@deq.isel.ipl.pt

because there several advantages over the aqueous media such as change in substrate specificity, selectivity and biocatalyst´s stability (Gupta and Roy, 2004 and Aires-Barros, 2000).

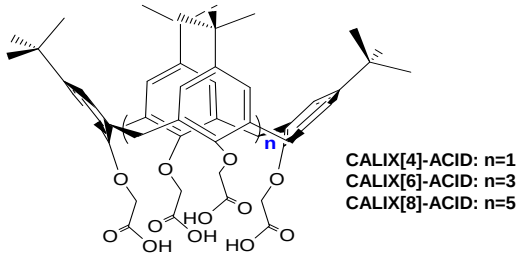

Figure 1 - Structure of *p-tert*-butylcalix[n]arene acid derivates.

The present work involves the use of lower rim substituted acid derivatives of *p-tert*-butylcalix[4,6,8]arenes, CALIX[4,6,8]-ACID (Figure 1) for selective extraction of myoglobin (Mb) which was used as a model protein.

Myoglobin is a multifunctional hemeprotein involved in several key physiological roles in animals as well as it exhibits peroxidase-like activity by catalyzing the oxidation of phenolic compounds in the presence of hydrogen peroxide (Carlsen *et al.*, 2003). The present work is concerned with extraction of myoglobin with CALIX[4,6,8]-ACIDs in organic media and biocatalysis of Mb-CALIX[6]-ACID complex which catalysed the oxidation of syringaldazine in the presence of hydrogen peroxide in organic medium.

MATERIALS AND METHODS

Materials

The structures and abbreviations of the extractants used in the present work are show in the Figure 1. The *p-tert*-butylcalix[n]arenes (n=4, 6 and 8) used as starting materials were prepared according to the Gutsche's procedures (Gutsche and Iqbal, 1990, Gutsche *et al.*, 1990 and Munch and Gutsche, 1990). These were in turn etherified with ethyl bromoacetate in the presence of anhydrous potassium carbonate in refluxing dry acetone for several hours (25h-72h, TLC control) (Iwamoto and Shinkai, 1992, Arnaud-Neu *et al.*, 1989). After appropriated work-up, the products were recrystallised from ethanol (*tetraethyl p-tert-butylcalix[4]arene tetraacetate, 1a*) or ethanol-dichloromethane (*hexaethyl p-tert-butylcalix[6]arene hexaacetate***,** *1b* and *octaethyl p-tert-butylcalix[8]arene octaacetate, 1c*), yielding the corresponding esters in moderate to good yields. Treatment of 1a-c with aqueous 10% tetramethylammonium hydroxide under reflux for 24h, afforded the calixarene acids CALIX[4,6,8]-ACID, after acidic workup (Chang and Cho, 1986).

Myoglobin from horse heart (Mb *c*) was obtained from Sigma Chemical Co. (USA) and all other chemicals were of analytical grade.

Methods

Extraction of Mb c With Calixarenes in Organic Solvents

Mb *c* solutions (14.7 μM) were prepared in buffers with different pH (see Table 1) as reported previously with some modifications (Oshima *et al.* 2002 and 2005). Calixarenes (CALIX[4,6,8]-ACID) were prepared either in chloroform or dichloromethane at a concentration range of 0.1 - 3.0 mM. The two phases (2, 3 and 5 mL), were mixed in stoppered glass

Table 1 - Experimental conditions for Mb *c* extraction.

Aqueous Phase	**Volume (mL)**	2, 3 and 5
	[Protein] (μM)	14.7
	pH	4.5 – 9.0 (10mM citrate buffer, 50mM phosphate buffer and 10mM glycine buffer)
Organic Phase	**Volume (mL)**	2, 3 and 5
	Solvent	CH_2Cl_2 and $CHCl_3$
	Extractant	**CALIX[4,6,8]-ACID**
	[Calixarene] (mM)	0.1, 0.2, 0.5, 1.0, 2.0 and 3.0
Temperature (ºC)		28
Contact Time (h)		0.5, 0.75 and 1

test tube and gently shaken for about 0.5 – 1 hr at 28 ºC. Phases were separated and protein concentration was measured by the absorbance of the Soret band peak (407 – 410 nm, Li and Mabrouk, 2003) both in aqueous and organic phases and the extractability was determined by the degree of extraction (E = 1 – [Mb c]$_{aq,eq}$/[Mb c]$_{aq,ini}$).

Protein Assay

Protein concentration in aqueous solutions was determined by Coomassie blue dye binding method by using BSA as the protein standard (Sedmak and Grossberg, 1977).

Biocatalysis

Pseudoperoxidase Activity of Mb c

The pseudoperoxidase activity of Mb *c* was assayed by using syringaldazine (Syr) and H_2O_2 as substrates as described previously (Goldberg *et al.*, 1983). The assay of pseudoactivity of Mb *c* in aqueous phase was carried out by using 15 μL of 1mM Syr dissolved in ethanol, 3 μL of 0.8 mM H_2O_2, 262 μL of 50 mM phosphate buffer pH 6.5 and 50 μL of Mb *c* solution (14.7 μM). The enzyme reaction was followed in a microtiter plate reader (Bio-Rad 680) at 550 nm due to oxidation of Syr to corresponding quinone at room temperature. The assay of pseudoperoxidase activity of Mb *c* – CALIX[6]-ACID complex in chloroform was performed by using a reaction mixture containing 100 μL of Syr 1mM dissolved in chloroform, 3 μL of 0.8 mM H_2O_2, 127 μL of chloroform and 100 μL of Mb *c* – CALIX[6]-ACID complex. One enzyme unit is defined as the amount of either Mb *c* or Mb *c* – CALIX[6]-ACID complex required to convert one μmole substrate into product per min under these experimental conditions.

Optimum pH of Pseudoactivity of Mb c

Mb *c* (14.7 μM) was prepared in different buffers as follows: 50 mM phosphate buffer pH 6.5, 50 mM citrate buffer pH 3.5 – 5.5 and 10 mM glycine buffer pH 7.5 – 9.0. Such initial Mb *c* solutions were extracted with CALIX[6]-ACID in organic medium and pseudoperoxidase activity of Mb *c* – CALIX[6]-ACID complex was determined as described above.

Kinetic Parameters

Specific activity of Mb *c* – CALIX[6]-ACID complex was determined by using aqueous initial solutions of Mb *c* (0.2 – 4.8 μM) in different buffer systems which was extracted with CALIX[6]-ACID in organic medium and pseudoperoxidase activity of Mb *c* – CALIX[6]-ACID complex was determined as described above. Apparent kinetic parameters (V'_{max}, K'_{cat} and K'_m) of the reaction catalysed by Mb *c* – CALIX[6]-ACID complex were determined by both Michaelis-Menten and Lineweaver-Burk plots by using the software Enzyme Kinetics – SigmaPlot v.10.0 (Systat Software, Inc.). All enzyme assays were carried out in triplicates by varying the concentration of Syr (0.01 – 0.6 mM) in the reaction medium as described previously.

Recovery of Mb c from organic phase to fresh aqueous solution

Mb *c* was recovered from organic phase to fresh aqueous solution by using buffers with different pH values (3.5 – 14.0) in order to disrupt the non-covalent Mb *c* – CALIX[6]-ACID complex. Therefore, equal volumes (1 mL) of organic phase containing the complex and aqueous solutions of buffer with different pH, were mixed in an end over end mixer, for about 2 min and phases were separated by centrifugation at 10,000 rpm for 2 min. UV-Vis spectra of both phases were carried out and degree of recovery (E') was determined by E' = [Mb c]$_{aq,eq}$/[Mb c]$_{org.ini}$ as described by Oshima *et al.,* 2005. Pseudoperoxidase activity of Mb *c* was assayed in both organic and aqueous phases in order to determine the recovery of pseudoactivity of Mb *c*.

RESULTS AND DISCUSSION

The extraction of Mb *c* at initial aqueous pH of 5.1 was investigated by using increasing concentrations of C4, C6 and C8 in chloroform as shown in Figure 1. As far as the degree of

extraction (*E*) is concerned, the highest value of 0.92 was obtained by using 3 mM CALIX[6]-ACID. However, regarding the A_{Soret} in organic phase, it was observed an increase in the following order: C8 > C6 > C4 (Figure 2).

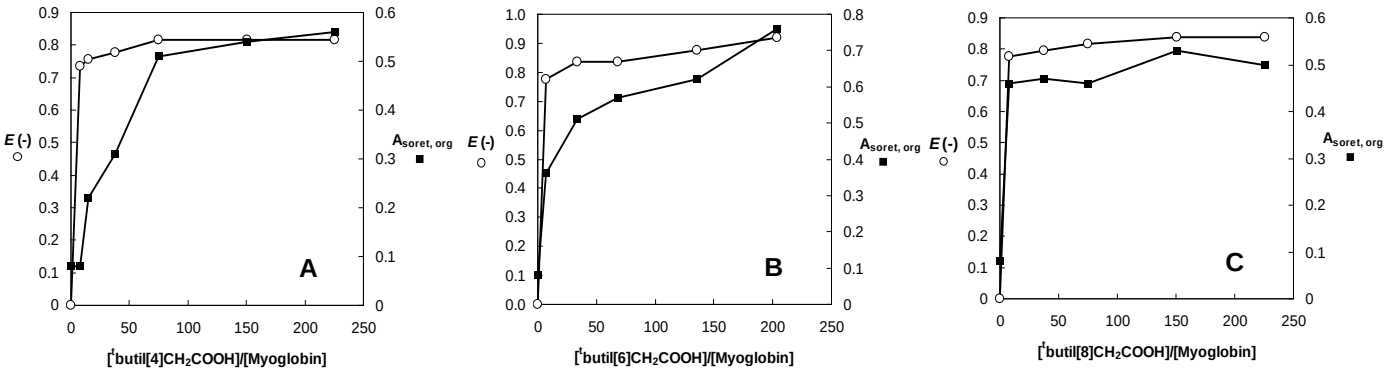

Figure 2 – *Effect of stoichiometric ratio of p-tert*-butylcalix[n]arenes acid derivatives: Mb c on the extraction Mb *c*, with $[Mb\ c]_{ini}$= 14.7μM at pH_{ini} = 5.1: A – extraction with CALIX[4]-ACID; B – extraction with CALIX[6]-ACID; C – extraction with CALIX[8]-ACID.

The structural changes of Mb *c* - CALIX[6]-ACID complex in chloroform were investigated by UV-Vis spectroscopy compared with the free Mb *c* in aqueous medium which revealed significant changes at Soret band peak as well as in Q band peaks (Figure 3).

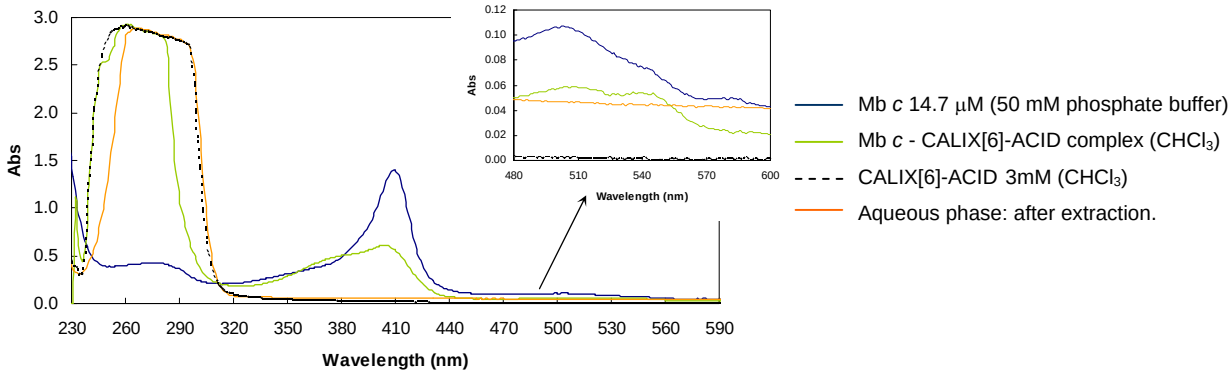

Figure 3 – UV-Vis spectra (230-590nm) of Mb *c* 50mM phosphate buffer pH 6.5, Mb *c* - CALIX[6]-ACID complex in $CHCl_3$ and aqueous phase after extraction.

Wiwatchaiwong *et al*. (2006) also reported similar changes in the Soret band of Mb *c* which was chemically modified with poly(ethylene oxide) in organic solvents. The effect of initial pH of Mb *c* solutions on degree of extraction was also investigated with CALIX[6]-ACID which revealed that protein extraction occurred in a wide range of pH values (4.5 – 9.0) (Figure 4). These data strongly suggest that there are several interactions involved between Mb *c* and CALIX[6]-ACID such as electrostatic and hydrophobic. On the other hand, protein extraction was observed at pH value higher than its pI which suggests apparently that at these pH values electrostatic interactions are not involved since the protein and CALIX[6]-ACID are charged negatively and therefore other interactions may play a role in protein extraction process in organic media.

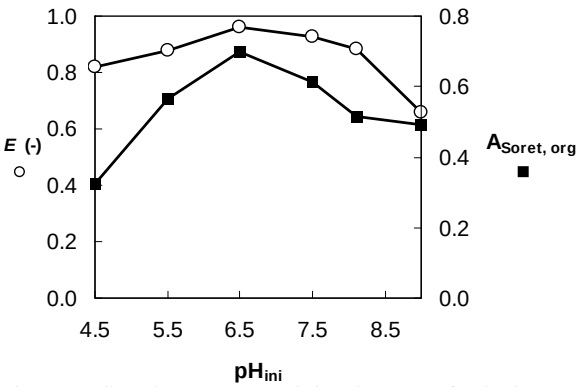

Figure 4 – Effect of pH_{ini} aqueous solution of 14.7 μM **Mb *c*** for the degree of extraction (*E*), with 3mM **CALIX[6]-ACID** in $CHCl_3$.

As far as biocatalysis is concerned, Mb *c* - CALIX[6]-ACID complex exhibited peroxidase-like activity (Figure 5 a) in chloroform and there is a linear relationship between [Mb *c* - CALIX[6]-ACID complex] and initial velocity of peroxidase activity (Figure 5 b). The effect of initial pH of Mb *c* solutions on peroxidase activity was also investigated which revealed that the highest specific activity was obtained at pH 6.5 (Figure 6). Apparent kinetic parameters (K'_m, V'_{max} and K'_{cat}) were determined for the reaction catalysed by Mb *c* - CALIX[6]-ACID complex which are presented in Table 2.

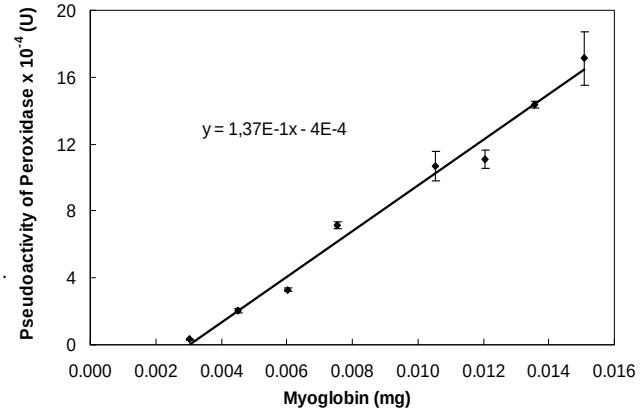

Figure 5 a – The effect of Mb *c* - CALIX[6]-ACID complex concentration on the pseudoperoxidase activity in organic medium (Mb *c* pH_{ini}=6.5).

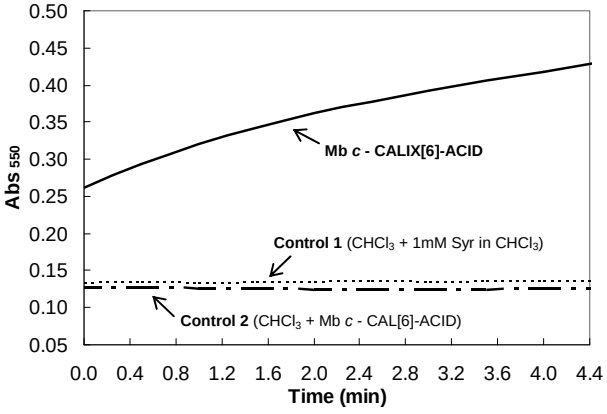

Figure 5 b – Progress curve of the Syr oxidation reaction in organic medium, catalyzed with Mb *c* - CALIX[6]-ACID complex (4.5 μg protein in $CHCl_3$).

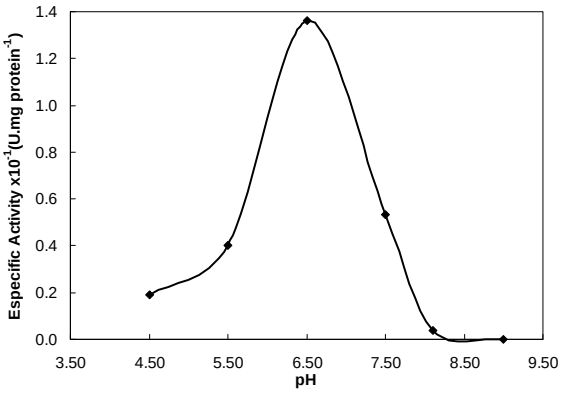

Figure 6 – The effect of pH_{ini} aqueous solution of Mb *c* on the specific activity of Mb *c* - CAL[IX6]-ACID complex in organic medium.

k'_{cat} / K'_m ($mM^{-1}\ s^{-1}$)	$1,83\times10^{-2} \pm 9,19\times10^{-3}$	$2,51\times10^{-2} \pm 2,50\times10^{-3}$	$3,31\times10^{-1} \pm 5,45\times10^{-3}$	$1,18\times10^{-1} \pm 2,07\times10^{-3}$

Subsequently, Mb *c* was recovered from organic phase to fresh aqueous solution by using buffers with different pH values (3.5 – 14.0) as shown in Figure 7. The degree of recovery (*E'*)

was found to be highest at pH 9.5 suggesting that alkaline pH was required to disrupt the Mb *c* - CALIX[6]-ACID complex. However, peroxidase activity of free Mb *c* in fresh aqueous solution exhibited the highest value at pH 10.5 and the recovery of enzyme activity was about 300 % compared with the initial aqueous solution of Mb *c*. Such recoveries of peroxidase activity higher than 100 % may be due to structural and conformational changes in Mb *c* molecules during this recovery process.

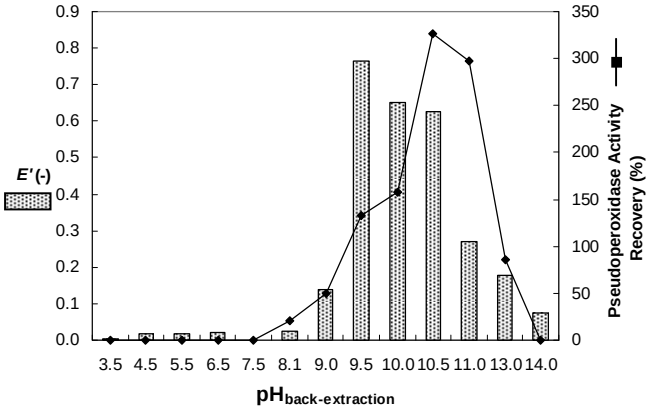

Figure 7 – Degree of back –extraction and pseudoperoxidase activity recovery of Mb *c* in an fresh aqueous solution.

Immobilization of Lecitase® Ultra in XAD 2 and XAD 4 under Ultrasound Irradiation

Karen M. Gonçalves[1]*, Rodrigo O. de Souza[1], Octavio A. C. Antunes[1], Enrique G. Oestreicher[2]

[1] Instituto de Química, Universidade Federal do Rio de Janeiro, Centro de Tecnologia, Bloco A, Cidade Universitária, 21945-970 Rio de Janeiro, Brazil

Keywords: Lecitase® ultra, amberlite XAD 2 and XAD 4, ultrasound irradiation

Abstract

Several immobilization conditions of Lecitase® ultra on amberlite XAD 2 and XAD 4 resin were investigated. The immobilization by adsorption led to an improved enzyme activity and recyclability. Using this approach, soy oil hydrolysis furnished linoleic acid in 12.4 and 11.9% in XAD 2 and XAD 4 respectively.

1. Introduction

Lipases (glycerol ester hydrolases; EC 3.1.1.3) are enzymes that catalyze the hydrolysis of triglycerides to glycerol and fatty acids. They are the most used enzymes in organic chemistry and its versatility leads to multiple industrial applications (Polaina J. and MacCabe A. P., 2007). Moreover, these enzymes may also catalyze the hidrolysis of phospholipids.

Lecitase® ultra, a new enzyme preparation with phospholipase A1 activity, was patented and made commercially available (Schroder, Novozymes A/S, 200). This enzyme is a preparation obtained from the fusion of the genes from lipase *Thermomyces lanuginosus* and phospholipase *Fusarium oxysporum*. Lecitase® ultra was initially developed for degumming process. However, it can be used as enantioselective biocatalyst in fine chemistry (Jose M. Guisan *et al.,* 2007).

Phospholipases have been described to undergo interfacial activation, similarly to lipases. Due to the nature of Lecitase® ultra, some authors found similarities between this enzyme and lipases, as it is hyper-activated by some detergents and it is able to recognize different esters (Jose M. Guisan *et al.,* 2007).

Although lipases and phospholipases present multiple industrial applications, they are often easily inactivated and are difficult to be separated from the reaction system for reuse. The ordinary method to enhance the operational lifetime, stability, recovery, reuse and continuous operation of lipase is to immobilize it on solid supports. The most commonly used immobilization approach is the adsorption because of its easy use and the reduced costs.

In this work, we disclose our results concerning the lipase activity of Lecitase® ultra supported onto hydrophobic amberlite XAD 2 and XAD 4 under different conditions, including ultrasound irradiation.

The ultrasound at low intensity levels favours the mass transfer because it enhances the movement of the liquid medium. However this phenomenon promote high local increases of

*Corresponding author. Tel + 55-21-25627248. E-mail: karen.goncalves@yahoo.com.br

temperature and pressure that can inactivate the enzyme, affecting its secondary structure (Sinisterra J.V., 1992).

Knowing that many beneficial effects in prevention of atherosclerosis, different types of cancer, hypertension and also improvement of immune function has been attributed to.CLA or Conjugated Linoleic acid, the preparations with best activities, after the optimization of immobilization procedures and the study of the effects of ultrasound irradiation, were applied on hydrolysis of soy oil intending to produce it and oleic acid. Which fatty acids are used as food supplements (Gabriel Fernandes *et al.*, 2006).

2. Materials and methods

2.1. Materials

Lecitase® ultra was obtained from Novozymes, amberlite XAD 2 and XAD 4 resin were purchased from Supelco. Acetone and *n*-hexane were obtained from Vetec and were used as received. The ultrasonic source was an ultrasonic bath Branson 2210 operating at 47 kHz. pH measurements were performed using Biocristal pH-stat and pH eletrod Quimis.

2.2. Immobilization of lipase

Crude Lecitase® ultra (16 mg of protein) was dissolved in 6 mL of buffer solution (sodium phosphate 0.1 M, pH 7.0) and mixed with 2 g of amberlite XAD 2 or XAD 4. Then 30 mL of cold acetone or hexane were added and the mixture was stirred under mechanical (*shaker*) or ultrasonic irradiation for 1 h at the immobilization temperature of 10.5°C. The immobilized lipase was collected by filtration, washed twice with *n*-hexane and the solvent was evaporated under reduced pressure. The immobilized lipase was then lyophilized for 1 h (Chwen-Jen Shieh *et al.*, 2007).

2.3. Enzyme activity assay

Lipase activity was checked by hydrolyzing a stabilized olive oil emulsion as proposed by Freire *et al*., (1997). The methodology was modified to determine the activity of the solid biocatalyst. The enzyme (1 mL for the enzyme solution or 0.1 g for the immobilized one) was feeded in a reactor, which contained 19.0 mL olive oil emulsion (5.0% w/v), a buffer (sodium phosphate 0.1 M, pH 7.0) and arabic gum solution (10.0% w/v). After the specified time (15 min), the reaction was quenched by adding 20 mL of acetone:ethanol solution (1:1). Control reactions were performed without the addition of the enzyme. Titration with NaOH 0.05 N were performed until pH 11. One unit of activity was defined as the amount of enzyme required to release 1 μmol of product per minute under the conditions described above.

2.4. Protein assay

Protein concentration was determined by the Bradford method (M.M. Bradford, 1976).

2.5. Immobilization efficiency

The immobilization efficiency was evaluated using the following parameters:
Lipase activity (U/g)
Specific activity (U/mg-protein)

$$\text{Protein loading ratio (\%)} = \frac{\text{amount of protein loaded}}{\text{amount of protein introduced}} \times 100\%$$

$$\text{Activity yield (\%)} = \frac{\text{specific activity of imobilized lipase}}{\text{specific activity of free lipase}} \times 100\%$$

2.6. Hydrolysis of soy oil

The optimized immobilized preparations were applied on soy oil hydrolysis as follows: 2.0 g of soy oil and 0.344 mL of distilled water (1:3) and 0.6 g of immobilized preparations (5 mg of protein) were mixed and the mixture was stirred at 300 rpm at 50°C for 6 h. The hydrolysis

yield was quantified by titration with NaOH 0.05 N using phenolphthalein as indicator and ethanol:ether solution (1:1) as a solvent. The quantification of fatty acids was performed using the following parameters:

- Acidity: Mililiters of NaOH solution to neutralize 100 g of sample: $\frac{V \times N \times f \times 100}{w}$

- Acidity on linoleic acid: Amount of fatty acids represented by linoleic acid:

$$\frac{V \times N \times f \times 100 \times 0{,}280}{w}$$

Where: V = volume of sample
N = normality of NaOH solution
f = correction factor of NaOH solution
w = weight of sample

3. Results and discussion

Lecitase® ultra presented significant activity for all immobilized preparations, however as shown in Table 1, the use of acetone and pre-treated XAD 2 (Table 1, Entry 7), shows better results than the same procedure without previous treatment (pre-treatment consisted of washing resins with distilled water followed by methanol) of XAD 2 (Table 1, Entries 2). The use of ultrasound as an activating source does not lead to any improvement on lipase activity and the temperature of ultrasound bath has not a significant influence on the enzymatic activity as shown in entries 5 and 10 (Table 1).

The use of *n*-hexane as solvent for the Lecitase® ultra immobilization gave interesting results (Table 1, Entry 9) for the reaction with XAD 2 without pre-treatment, leading to a specific activity close to the best result obtained with acetone (Table 1, Entry 7). Again, ultrasound does not enhance the lipase activity under the conditions used in this work.

The difference between protein loading ratios was not significant on protocols used, not including the case that a solvent was not used (Table 1, Entry 1).

Table 1: Results obtained for the Lecitase ® Ultra immobilization in XAD 2:

Entry	Solvent	Stirring	Temperature	Activity (U/g)	Specific activity (u/mg de ptn)	Protein Loading ratio (%)	Activity yield (%)[d]
1 [a]	-	300 rpm	10.5°C	26.6	7.97	41,5	107.41
2 [a]	Acetone	300 rpm	10.5°C	103.74	13	99,3	175.2
3 [a,c]	Acetone	-	24- 44°C	17.38	2.18	99,4	36.33
4 [a,c]	Hexane	-	24- 44°C	46	7.2	79,8	120
5 [b,c]	Acetone	-	24- 44°C	62.36	7.75	99,9	129.17
6 [b,c]	Hexane	-	33 – 50°C	62.69	8.13	95,8	135.5
7 [b]	Acetone	300 rpm	10.5°C	136.12	16.96	100,0	249.41
8 [b]	Hexane	300 rpm	10.5°C	30	3.77	98,8	55.44
9 [a]	Hexane	300 rpm	10.5°C	105.68	13.35	98,5	222.5
10 [b,c]	Acetone	-	14 – 17°C	73	9.26	97,9	136.18

[a] XAD 2 was used without previous treatment [b] XAD 2 was washed with methanol and water before immobilization
[c] Ultrasound was used
[d] Activity yield **(%) =** Specific activity of immobilized lipase **x** 100 / Specific activity of free lipase

The best conditions obtained were applied for XAD 4 resin and the results are summarized in Table 2. As shown in Table 2, conversely to the results obtained for XAD 2, the use of

ultrasound improved the specific lipase activity when compared to the same reaction profile under only mechanical stirring (Table 2, Entries 1, 2 and 3).

Table 2: Results obtained for the Lecitase ® Ultra immobilization in XAD 4

Entry	Solvent	Stirring	Temperature	Activity (U/g)	Specific activity (U/mg of ptn)	Protein Loading ratio (%)	Activity yield (%)[d]
1 [a]	Acetone	300 rpm	10.5°C	77.87	9.72	99.4	142.94
2 [b]	Acetone	300 rpm	10.5°C	95.87	11.94	99.6	175.59
3 [a,c]	Acetone	-	14-17°C	103.17	13.71	93.4	201.62

[a] XAD 4 was washed with methanol and water before immobilization [b] XAD 4 was used without previous treatment
[c] Ultrasound was used
[d] Activity yield **(%) =** Specific activity of immobilized lipase **x** 100/Specific activity of free lipase

The amount of protein immobilized on amberlite XAD 4 under sonication (Table 2, Entry 3) was lower than the others, however its specific activity increased, probably because of difusional limitations were reduced.

3.1. Storage stability at 4°C

The storage stability of the immobilized preparations which presented the best specific activities (Table 1, entries 7 and 9) to amberlite XAD 2 resin and to amberlite XAD 4 resin (Table 2, entry 3) were observed during several days (Figure 1). This could be observed in terms of lipase activity.

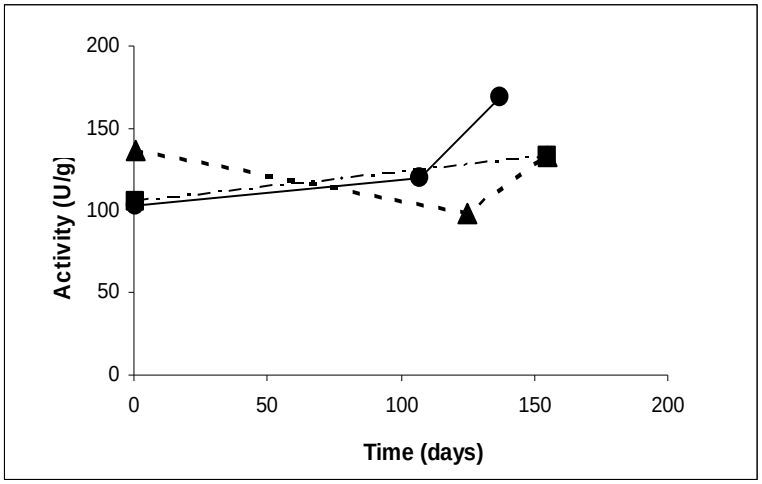

Figure 1. Storage stability.
Immobilized preparation on XAD 2 resin: 7(- - -▲- - -), 9 (– –■– –).
Immobilized preparation on XAD 4 resin: 3 (—●—)

As shown in Figure 1, the enzyme activity was slightly higher after 150 days of storage at 4°C, which could indicate that the enzyme can be used after almost 6 months without loose of activity. This increase in enzymatic activity could be a normal zone of variation, depending on the enzyme used, however it has to be investigated.

3.2. Hydrolysis of soy oil

On the hydrolysis of soy oil the acidity obtained for the reaction catalyzed by XAD 2 (Table 1, Entry 7) and XAD 4 (Table 2, Entry 3) was 44.3% and 42.4%, respectively. When the acidity was quantified based on amount of linoleic acid, the results obtained were 12.4 and 11.9% to XAD 2 and XAD 4, respectively.

4. Conclusions

The different conditions applied on immobilization of Lecitase® ultra showed that the use of *n*-hexane as solvent offers better results when amberlite XAD 2 is not pre-treated. Probably the hydrophobic nature of this solvent facilitates the enzymes access to the support against the other organic substances in the resin. However, when acetone was used, amberlite needed to be pre-treated.

The ultrasound irradiation does not improve the hydrolysis activity of Lecitase® ultra on XAD 2. However, difference between the amounts of protein adsorbed is observed. While the ultrasound irradiation improves the adsorption of protein when XAD 2 was not pre-treated (Table 1, Entries 4 and 6), the lipase activity has not significant alterations. In case of XAD 4, ultrasound improves the activity with acetone as solvent.

Therefore, Entries 7, 9 (Table 1) and 3 (Table 2) are the best conditions to immobilize Lecitase® ultra on amberlite XAD 2 and XAD 4. The immobilized preparations (Table 1, Entry 7 and Table 2, Entry 3) present interesting results on hydrolysis of soy oil, made it available to produce fatty acids as linoleic and oleic acids, important food supplements.

Keywords: Industrial Biotrickling filter, lab-scale biotrickling filter, Hydrogen sulfide, Bacterial Community diversity, Clone library
Topic: Integration of life sciences & engineering.

Abstract

The bacterial diversity in a lab-scale and an industrial biotrickling filter treating high loads of hydrogen sulfide (H_2S) were assessed by using molecular biology techniques. Both reactors were operating for more than 6 months with sustained elimination capacities above 90% when samples were withdrawn. In both cases the same experimental procedure was applied, 16S rRNA gene clone libraries were created and clones were clustered into operational taxonomic units (OTUs) for further analysis. The different operational conditions as well as other significant factors like sampling or DNA extraction induced unexpected results in the industrial reactor clone library. Whereas the lab-scale clone collection showed high percentage of sulfur oxidizing bacteria (45%), the industrial bioreactor clone library did not have clones affiliated to any genera of sulfur oxidizers. As a result, industrial library obtained is believed not to be completely representative of the diversity existing in the reactor. Although industrial scale bioreactor showed higher number of OTUs, nearly all the sequences were related to the non sulfur related family Enterobacteriaceae. In contrast, the lab-scale bioreactor clone library demonstrated to have less differentiated OTUs but widely distributed phylogenetically, which indicates the higher representativeness of this collection. Experimental factors which led to these results are analyzed and better knowledge on the implementation of molecular techniques when investigating industrial scale bioreactors is obtained.

1 Introduction

Biogas, that contains secondary components like hydrogen sulfide (H_2S), is produced in the anaerobic treatment of wastewater treatment plant sludge. H_2S is a corrosive, toxic and odorous gas, which has been successfully degraded in biotrickling filters (Fortuny et al. 2008).

A comprehensive study of the communities in these biologic reactors has been shown to be critical to the understanding of the whole biodegradation process (Borin et al., 2006). The

methods used in the traditional culture-dependent approach for assessing the microbial community are often biased since it has been estimated that less than 1% of all microorganisms are cultivable by standard methods (Amann et al., 1995). Nevertheless, techniques used in the novel molecular approach targeting the small subunit rRNA-encoding genes, can solve this bias problem. Thus, a more representative picture of the microbial populations could be obtained.

Several studies have been reported analyzing lab-scale as well as industrial bioreactors communities by using molecular tools (Sakano and Kerkhof, 1998; Friedrich et al., 2002; Sercu et al., 2006). In this study the cloning and sequencing methodology have been successfully applied in a lab-scale biotrickling filter (LSBTF) treating high concentrations of H_2S. However, several problems arose when applying lab-scale molecular biology procedures to the industrial scale biotrickling filter (ISBTF). To our knowledge, this is the first research to study the microbial communities of an industrial scale biotrickling filter degrading high loads of H_2S and to analyze the factors influencing negatively on the coverage of the clone library obtained.

2 Materials and Methods extensive

Experimental setups.

In this work, two biotrickling filters (BTFs) were studied. The start-up in both bioreactors was carried out using sludge from the same municipal WWTP as inoculum. Both BTFs were continuously operated for six months at an empty bed residence time 180 s for gas treatment with inlet concentrations of 2000 ppm_v of H_2S (55.6 g H_2S m^{-3} h^{-1}). Details of the LSBTF can be found elsewhere (Fortuny et al., 2008). It was designed with a single compartment and packed with 3 L of polypropylene HD Q-PAC (Lantec) with a 4 x 4 mm grid opening. The pH was controlled between 6.5 and 7.5 by adding acid or base. The bioreactor worked at room temperature. On the other hand, the ISBTF, located in a wastewater treatment plant, was designed as 4 separated modules with a bed volume of 5.2 m^3 packed with 1" Pall rings. The pH of the ISBTF was set between 2 and 3, and the temperature was allowed to fluctuate according to environmental conditions, from 0 to 20 ºC. In order to keep the pH at the fixed setpoint, a flow of make–up water (effluent from the WWTP containing the following average values: BOD 5 mg l^{-1}, TKN 7 mg l^{-1} and P_{total} 7 mg l^{-1}) was introduced at a flow rate of 30 m^3 d^{-1}.

Under these conditions, elimination capacities around 50 g H_2S m^{-3} h^{-1} were achieved for nealy the whole experimental period. In the LSBTF, metered amounts of H_2S, N_2 and air (0.2, 77.3 and 22.4 % respectively) were used to simulate a controlled biogas inflow whereas in the ISBTF, H_2S laden biogas was obtained directly from the biogas storage tanks of the anaerobic sludge treatment produced in the WWTP. On average, industrial biogas composition was 69% CH_4, 29% CO_2, 1% N_2, and others (including H_2S). In the lab-scale reactor N_2 was used instead of CH_4 for security reasons. More details of the LSBTF, the mineral medium used as make-up water, other operational conditions and analytical methods can be found elsewhere (Fortuny et al., 2008).

DNA isolation and 16S rRNA gene amplification.

In the lab-scale case, biomass samples were withdrawn on day 189 of operation from two sampling ports situated at different heights in the reactor, 17 cm and 34 cm. Both biomass samples were mixed in a 1:1 ratio (w/w) and DNA extraction was carried out. Similarly, in the ISBTF each module was sampled. Separated DNA extractions were carried out for biomass from each module. DNAs from ISBTF modules were mixed prior to PCR amplification according to the DNA concentration obtained to have the same quantity of DNA of every module in the resulting mixture. DNA was tested and preserved as described elsewhere (Chihua and Banks, 2006).

The small subunit (SSU) rRNA gene was polymerase chain reaction (PCR) amplified from

genomic DNA extracted from the environmental samples using the universal bacterial primers 8F and 926R (Molbiol, Germany). PCR reactions were performed as described elsewhere (Chihua and Banks, 2006) but containingd 100 ng of template DNA.Then, 16S rRNA gene fragments were cloned with the TOPO TA Cloning® Kit for Sequencing (Invitrogen, CA, USA) according to the manufacturer's instructions.

Sequencing and phylogenetic reconstruction.

One hundred clone inserts were sequenced for each clone library. In the LSBTF case, clones were sequenced in full with pUC/T3-T7 primers by Macrogen (Korea) wheras in the ISBTF clones were sequenced only with T3 primer, obtaining partial sequences. All sequences were checked for chimeric artifacts by using the CHIMERA_CHECK program of the Ribosomal Database Project (Maidak et al., 2000) and for similar sequences with the ClustalW program. Sequences (approximately 1500bp in LSBTF case or around 800pb in the ISBTF collection) were compared with similar sequences of the reference organisms by a BLAST search (Altschul et al., 1997). Sequences with the same first accession number were grouped into OTUs. Thus, the clustering process was based on the BLAST results obtained for every clone. Similarity between clones within the same OTU was studied by sequence comparison using ClustalW.

Rarefaction analysis.

The rarefaction analysis was calculated using the defined OTUs. The software Analytic Rarefaction (version 1.3, S.M. Holland, http://www.uga.edu/~strata/software/) was used to perform rarefaction analysis. The 16S rRNA gene sequences of the clones have been submitted to the Genbank /EMBL/DDBJ to obtain the corresponding accession numbers. The coverage of the clone library was calculated according to the following equation: $C= 1 - (n/N) * 100$, where n is the number of unique clones and N is the total number of clones examined (Ravenschlag et al., 1999).

3 Results and Discussion

Microbial populations are predictable to be determined by the operational conditions set in the bioreactors, that is, by the microenvironments created by gradients of pH, temperature, O_2 concentration and pollutant concentration, among other factors. Thus, dissimilar sulfur oxidizing communities were expected among the LSBTF and the ISBTF just because of the pH differences. Conversely microbial community collection obtained for the ISBTF was found to be biased and not to represent the whole bacterial community of the reactor.

Assesment of bacterial communities.

In the present work, microbial communities of two BTFs, lab-scale and industrial scale, degrading high loads of H_2S were investigated. Accordingly with the pollutant being degraded, sulfur-oxidizing bacteria were expected to be predominant in both clone collection of both BTFs. In the LSBTF, neutrophilic bacteria were predictable whereas in the ISBTF, acidic communities were likely the most predominant. Biodiversity in the reactors are influenced by operational conditions such us packing material, pollutant load, pH, etc. Both BTFs have inert packing material which could diminish biological diversity in comparison to organic materials. Also, extreme H_2S concentrations may affect the presence of specific groups of bacteria like sulfur oxidizing bacteria (SOB). In spite of these factors, biomass grows forming biofilms in this sort of reactors what creates microenvironments and favors variety of ecological conditions and consequently increase bacterial assortment.

In this work, the molecular approach was selected to overcome culture-techniques problems and to obtain representative results of the microbial communities present in the reactors. Despite 16S rRNA gene approach also have biases such as preferential DNA extraction or PCR amplification; it would cover most of the populations existing in the biological sample. Such biases emerged during the molecular procedure could modify population relative abundances in the clone collection, indicating that this cloning-sequencing methodology

cannot be considered quantitative. Nevertheless, if good practices are applied results obtained in clone libraries are expected to be directly related to communities present in the bioreactors.

Although results obtained in both clone collections showed that there is a high bacterial diversity in this kind of bioreactors, the industrial scale library demonstrated to have more number of differentiated OTUs (62) but less widely distributed phylogenetically than the lab-scale collection (24). The quantity of OTUs was likely determined by the fact that industrial scale collection was obtained by sequencing only with T3 primer, thus only partial sequences of 750-850 bp were acquired. This could reduce the specificity of the sequences leading to find more OTUs in the clone collection. Conversely, LSBTF's 16S rRNA gene clone library was constructed with near full-length 16S rRNA gene sequences (1500 bp). Although the number of OTUs determines some of the regular analysis usually carried out in this type of studies, it was not a particular issue in the analysis of the ISBTF collection.

Rarefaction analysis demonstrated that the LSBTF clone library constructed was enough representative of the bacterial diversity (curve not shown). ISBTF collection was less suitable describing the specific bacterial richness in terms of species. Nevertheless, concerning ribosomal data project (RDP) genera classification, only 3 genera (Kluyvera, Citrobacter and Enterobacter) comprised the 84% of the clones showing that in terms of genera the community was theoretically less diverse. Coverage percentage was higher in the LSBTF clone library (nearly 68%). In the industrial case coverage was only 29%, lower that values found in literature for industrial bioreactors (Friedrich et al.,2002), demonstrating that an important fraction of microbial diversity is not covered and consequently, clone collection obtained could not be sufficiently representative.

A wide variety of OTUs were found to be SOB in the LSBTF (Table 1), including 45% of the clones. They were closely related to various SOB species such as: *Thiothrix Lakustris*, *Thiothrix sp. CT3*, *Sulfurimonas denitrificans*, *Thiobacillus denitrificans*, *Thiobacillus sajanensis* and *Thiobacillus plumbophylus*. Unexpectedly, only one clone out of 87 could be related to a SOB genera in the ISBTF collection. One clone is affiliated to an uncultured *Pseudomonas spp*. Some *Pseudomonas spp.* have been previously related to sulphur oxidation (Shibata and Kobayashi, 2006) or found in sulfur oxidizing biofilms (Ferrera et al., 2004). None of the typical SOB genera such us Acidithiobacillus was found in the bioreactor.

In table 1 is possible to observe the most abundant clones found in both libraries. Only OTUs comprising more than 3 clones are showed. ISBTF presented species affiliated with Kluyvera, Enterobacter and Rahnella among other genera within the Enterobacteriaceae family.

Table 1. Phylogenetic affiliation of the most abundant clone sequences retrieved in both clone libraries: L: lab-scale, I: industrial scale. OTUs composed by more than 3 clones are represented. Cn: clone number, , S: Similarity

High removal efficiencies achieved in the reactor in long term operation (over six months) indicated that SOB must be present in the bioreactor in enough number to degrade the high loads of H_2S treated. The scarce representation of SOB in the industrial library could be caused by different factors affecting concomitantly.

Causes of low representation of SOB.

As previously stated, the representativeness of the clone library obtained for the industrial bioreactor is uncertain. Acidic SOB are supposed to be degrading hydrogen sulphide at high rates inside the ISBTF and were not found in the collection of clones. Several causes could be not only influencing the relative abundance of the species but also diminishing the presence of some groups of bacteria to the extent that some of them do not appear in the collection. Methodological aspects when applying the same procedure used to construct the lab-scale clone collection might have been key factors to make SOB not predominant and even present in the library.

First of all, representativeness is influenced by the sampling technique. In the lab-scale biofilters samples were withdrawn at two heights, representing the sample volume almost 20% of the total reactor volume. However, ISBTF was sampled for the 4 modules but the total volume sampled represented less than 5% of the total volume due to the technical difficulties when sampling this industrial scale plug flow bioreactor. The 4 modules were sampled and individual DNA extractions were carried out. According to the quantity of elemental sulfur found in the modules, H_2S oxidation is supposed to be accomplished in the two first modules of the bioreactor and mainly in the first one. In the rest of the bioreactor, other types of bacteria would be predominant since almost no source of sulfur would be available. As a result, the vast majority of SOB bacteria could be settled in these parts of the reactor. Prior to PCR amplification, DNA from each module was mixed taking into account the DNA concentration obtained. This could lead to a drastic reduction of the SOB DNA in the resulting sample and consequently in the clone collection.

Another factor affecting the molecular procedure is the elemental sulfur found in the biological samples. The presence of sulfur is thought to be responsible of the low DNA quantities obtained from the industrial bioreactor. Conversely, in the LSBTF, almost no elemental sulfur was found in the samples. In spite of the similar operational conditions, in the lab-scale biofilters oxygen could be distributed in a better way so less elemental sulfur was produced. Thus, the grid used as packing material could be more suitable and favor O_2 transference in front of the Pall rings used in the ISBTF.

As previously stated, pH is a key factor determining populations in the bioreactor. LSBTF was kept at neutral conditions during the whole experimental period. Normally, in lab-scale setups pH is controlled by adding HCl or NaOH. In the industrial case, it would be expensive to control pH in the same way so make-up water is used for that purpose. Make-up water used in this case comes from the wastewater treatment plant effluent, which still contains microorganisms (most of them enteric bacteria, a normal part of the gut flora found in the intestines of humans) as well as BOD, nitrogen and phosphorous. Make-up water average rate used for pH control was 30 $m^3\ d^{-1}$, so this constant addition of microorganisms and nutrients could result in a regular re-inoculation of the reactor. These non sulfur oxidizing bacteria could become predominant in those parts of the reactor where H_2S was not significant, that was likely in the 3^{rd} and 4^{th} module. Moreover, Enteriobacteriaceae are facultative anaerobes so oxygen requirements were not decisive for them, resisting the low levels of oxygen that existed in the reactor. This could considerably explain why Enterobaceriaceae family is so predominant in the clone library obtained.

4 Conclusions

In this study, a molecular approach has been used to characterize the microbial diversity in an industrial as well as in a lab-scale biotrickling filter. Clone libraries potentially representing most abundant species present were created. Whereas lab-scale library was representative

of the bacterial richness present in the reactor, the industrial clone library did not show any SOB. That led to conclude that the collection obtained could not have enough representativeness. Some key factors were identified as possible causes of this lack of fidelity between the real community present in the reactor and the diversity obtained in the clone library. Total sample volume, the presence of sulfur when extracting the DNA as well as the mixture of each volume DNA could have distorted the relative abundances of bacteria in the collection.

Finally, the continuous re-inoculation effect caused by passing through the reactor a high flow rate current of make-up water containing enteric bacteria from the effluent of the WWTP could also determine the high abundance of this group in the industrial clone library.

Keywords: Tomato pomace; Immobilized Metal Affinity Chromatography; polygalacturonase; lignocellulosic enzymes; *Pleurotus ostreatus*.
Topic: Multi-scale and/or multi-disciplinary approach to process-product innovation

Abstract

A strain of *Pleurotus ostreatus* was grown in submerged culture in tomato pomace as sole carbon source for production of polygalacturonase. The culture of *P. ostreatus* revealed a peak of polygalacturonase activity (2181 U/L) on 4th day with specific activity of 42.8 U/mg protein. Differential chromatographic behaviour of polygalacturonase, xylanase and laccase from *P. ostreatus* was investigated on immobilized metal chelates. The effect of ligand concentration, pH, the length of spacer arm and the nature of metal ion was studied for enzyme adsorption on immobilized metal affinity chromatography (IMAC). The presence of imidazole in the equilibration buffer abolished the adsorption of the enzymes to immobilized metal chelates. A one-step purification of polygalacturonase from *P. ostreatus* was devised by using a column of Sepharose 6B-EPI 30-IDA-Cu(II). Purified enzyme exhibited a specific activity of about 1600 U/mg protein, final recovery of enzyme activity of 80% and a purification factor of about 65. The purified enzyme preparation was analysed by SDS-PAGE as well as by *in situ* detection of enzyme activity. Purified preparation of polygalacturonase exhibited a pH and temperature optima of activity at 7.0 and at 50ºC, respectively. The kinetic parameters (V_{max}, K_m, K_{cat}, and K_{cat}/K_m) of purified enzyme were found to be 5530.8 ± 260.7 U/mg of protein, 13.23 ±2.79 mg/ml of polygalacturonic acid, 5553.01 ± 261.7 $s^{-1}$and 419.72 $s^{-1}.mg^{-1}$, respectively. Purified enzyme exhibited a half life (t ½) of 60 ± 7.45 min and 35 ± 0.37 min at 50ºC and at pH 6.0 and 7.0, respectively.

1 Introduction

Food processing industries and agriculture produce annually a huge amount of wastes that are both a disposal and an environmental problem. During tomato processing, a huge amount of the starting raw product represents solid waste material which is known as tomato pomace. It consists of tomato peel, seeds as well as some pulp. The chemical composition of tomato pomace includes proteins, lipids, carbohydrates, amino acids, caratenoids and minerals (Alvarado, Pacheco-Delahaye, Hevia, 2001; Knoblich, Anderson, Latshaw, 2005; Valle, Cámara, Torija, 2006).

Pectinases or pectinolytic enzymes are a group of enzymes that catalyse altogether the degradation of pectic substances present in vegetable cells. Microbial pectinases play an important role in biotechnological applications, namely in food industry (fruit juice extraction, coffee and tea fermentation, oil extraction, improvement of chromaticity and stability of red wines), textile industry (bioscouring of cotton fibers), paper and pulp industry and in waste water treatment. On the other hand, pectinases are used in novel applications such as the purification of plant viruses (Jayani,

Saxena, Gupta, 2005; Gummadi, Panda, 2003) However, industrial production of pectinolytic enzymes makes use almost exclusively of *Aspergillus niger* strains.
Polygalacturonases (EC 3.2.1.15 and EC 3.2.1.67) are pectinolytic enzymes that catalyse the hydrolytic cleavage of the polygalacturonic acid chain with the introduction of water. These enzymes are of industrial interest since they are used in specific applications, such as in baby and functional foods [8]. There is only one report in the literature about the production of endo and exo-polygalacturonases (EC 3.2.1.15 and EC 3.2.1.67, respectively) from *Coriolus trogii* (Levin, Forchiassin, 1998). To our knowledge, the production of such enzymes from *P. ostreatus* has not been reported in the literature.
Since this enzyme is secreted extracelularly by white-rot fungi as well as other lignocellulosic enzymes, it is of great interest to devise a simple and cheap separation method for these enzymes in order to be used in different industrial applications. Immobilized metal affinity chromatography (IMAC) has been used for purification of wild-type and recombinant proteins. The interactions between accessible coordination sites of metal ions and electron-donating groups present on the protein surface are responsible for retention of proteins in IMAC. Several factors affect the adsorption process, such as the nature of metal ion involved in coordination, the matrix, the length of spacer arm, the ligand concentration, the pH and buffer used (Porath, 1992; Gutiérrez, Valle, Galán, 2007).
The present work is concerned with the production of polygalacturonase from *P. ostreatus* by using tomato pomace as sole carbon source in culture medium. Subsequently, the chromatographic behavior of this enzyme as well as other lignocellulosic enzymes (i.e xylanase and laccase) on immobilized metal chelates will be investigated as a function of ligand concentration, pH, length of spacer arm and nature of metal ion. The selective adsorption of polygalacturonase on immobilized metal chelates will be carried out for purification of this enzyme with high yield and purity and kinetic characterization of the purified enzyme will be presented.

2 Methods

2.1 Growth and maintenance of fungal strain

The strain of *P. ostreatus* was grown and maintained in solid potato dextrose agar (PDA). For enzyme production, the strain was grown on liquid media, containing carbon source (either 20 g/L of tomato pomace or 10 g/L of pectin), 1 g/L of $(NH_4)_2SO_4$, 0.125 g/L of $CaCl_2$, 1 g/L of $NaH_2PO_4.H_2O$ and 0.5 g/L of $MgSO_4.7H_2O$. The pH was adjusted to 5.5 prior to autoclaving.

2.2 Fungal growth conditions

Fungal growth conditions were described as reported previously (Freixo , Karmali, Arteiro, 2008).

2.3 Enzyme assays

Enzymatic assays were performed as described in the literature (Freixo, Karmali, Arteiro, 2008).

2.4 Preparation of chromatographic matrices

Chromatographic matrices were prepared as described in the literature (Freixo, Karmali, Arteiro, 2008).

2.5 Adsorption tests of polygalacturonase, xylanase and laccase on metal chelates

As previously described (Martins, Andrade, Karmali, Serralheiro, 2006), a rapid batch method carried out in ELISA microtiter plates was used to study the adsorption of polygalacturonase, xylanase and laccase on the following Cu(II), Ni(II), Zn(II) and Co(II) metal chelate supports: Sepharose 6B- BDGE-30-IDA- M(II), Sepharose 6B- EPI-30-IDA- M(II) and Sepharose 6B- EPI-10-IDA- M(II).

2.6 Purification of polygalacturonase from *P. ostreatus*
Based on the results of the batch mode on ELISA microtiter plates, a set of experimental conditions were selected to purify polygalacturonase from this fungal strain, as described in the literature (Freixo, Karmali, Arteiro, 2008).

2.7 Kinetic characterization of purified polygalacturonase from *P. ostreatus*
Kinetic characterization of purified polygalacturonase from *P. ostreatus* was performed as described in the literature (Freixo, Karmali, Arteiro, 2008).

3 Results and Discussion

3.1 Production of polygalacturonase and protein content in culture supernatants
The cultivation of *P. ostreatus* on tomato pomace medium was followed for 14 days (Fig.1) and displayed a bell-shaped curve for protein content as well as for polygalacturonase activity. Pectinlyase activity in the fermentation broth was also determined during the cultivation process and no activity was detected in culture supernatants. The culture of *P. ostreatus* revealed a peak of polygalacturonase activity (2181U/L of fermentation broth) on the 4th day of culture with a specific activity of 42.8U/mg protein (Fig. 1). This data revealed that at 3rd day of incubation, polygalacturonase activity reached a maximum value and then it exhibited a decrease in activity. This change in enzyme activity may be due to the accumulation of microbial metabolites in the fermentation broth.

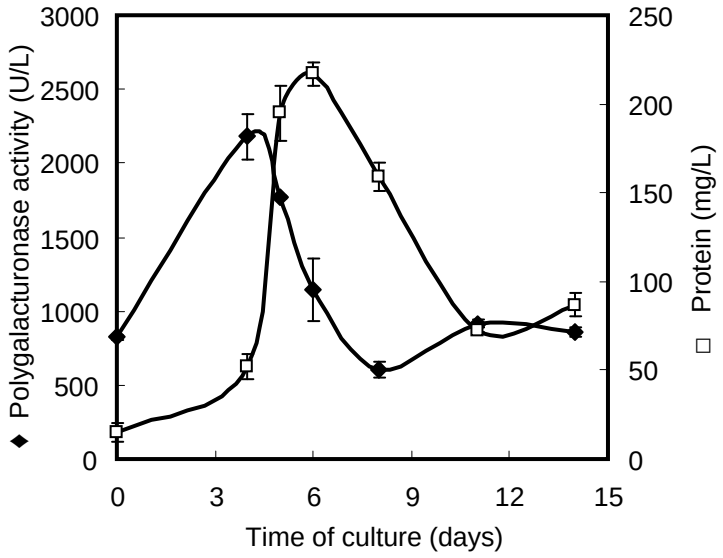

Figure 1 – Total protein content and polygalacturonase activity in shaken cultures of *P. ostreatus* by using tomato pomace as a carbon source which was assayed in culture supernatant of fermentation broth. ♦- Polygalacturonase activity and □ – Protein content.

3.2 Chromatographic behaviour of polygalacturonase, xylanase and laccase on immobilized metal chelates
The chromatographic behaviour of these lignocellulosic enzymes is summarized in Table 1, for different stationary phases (Sepharose 6B-BDGE 30 – IDA, Sepharose 6B-EPI 30–IDA, Sepharose 6B–EPI 10–IDA) as well as for different immobilized metal ions.

Table 1 – Results from adsorption tests of lignocellulosic enzymes from *Pleurotus ostreatus* on immobilized metal chelates.

	pH	Stationary phase	Cu(II)	Ni(II)	Zn(II)	Co(II)
Xylanase	6	BDGE 30, EPI 30, EPI 10	–	–	–	–
	7	BDGE 30, EPI 30, EPI 10	±	–	–	–
	8	BDGE 30, EPI 30, EPI 10	±	–	–	–
Polygalacturonase	6	BDGE 30, EPI 30, EPI 10	+	–	–	–
	7	BDGE 30, EPI 30, EPI 10	+	±	–	–
	8	BDGE 30, EPI 30, EPI 10	+	±	–	–
Laccase	6	BDGE 30, EPI 30, EPI 10	–	–	–	–
	7	BDGE 30, EPI 30, EPI 10	±	–	–	–
	8	BDGE 30, EPI 30, EPI 10	+	–	–	–

3.3 Purification of polygalacturonase by using imidazole in equilibration buffer

The combination of tailor-made stationary phases for IMAC and a correct choice of the adsorption conditions permitted to design a one-step purification procedure for polygalacturonase from *P. ostreatus*. The chromatographic behaviour of polygalacturonase on Sepharose 6B – EPI 30 – IDA-Cu(II) colum at pH 6.0 (Fig.2b) resulted in partially purified enzyme according to the electrophoretic analysis (data not shown). However, the presence of 1mM imidazole in the equilibration buffer abolished the adsorption of several protein contaminants to Sepharose 6B – EPI 30 – IDA- Cu(II) column including laccase and xylanase (data not shown). Hence, polygalacturonase was desorbed from the column with a linear gradient of imidazole (Fig. 2c) with a specific activity of about 1600 U/mg protein, a final recovery of enzyme activity of about 80% and a purification factor of about 65 (Table 3). The purity of chromatographic fractions from Sepharose 6B – EPI 30 – IDA- Cu(II) was analysed by SDS-PAGE which revealed that the purified fractions exhibited two protein bands with Mr of 60 and 70 kDa which was coincident with an activity band of polygalacturonase with Mr of 65 kDa.

Table 3 – Purification of polygalacturonase from *Pleurotus ostreatus* by Immobilized Metal Affinity Chromatography on Sepharose 6B – EPI 30 – IDA - Cu(II) column at pH 6 in the mobile phase containing 1mM imidazole.

	Purification Steps	Total protein (mg)	Total activity (IU)	Specific activity (IU/mg protein)	Recovery (%)	Purification factor
1.	Culture supernatant	0.881	21.24	24.109	100	1
2.	EPI 30-Cu (II) column eluate	0.0109	17.3	1587.1	81.4	65.8

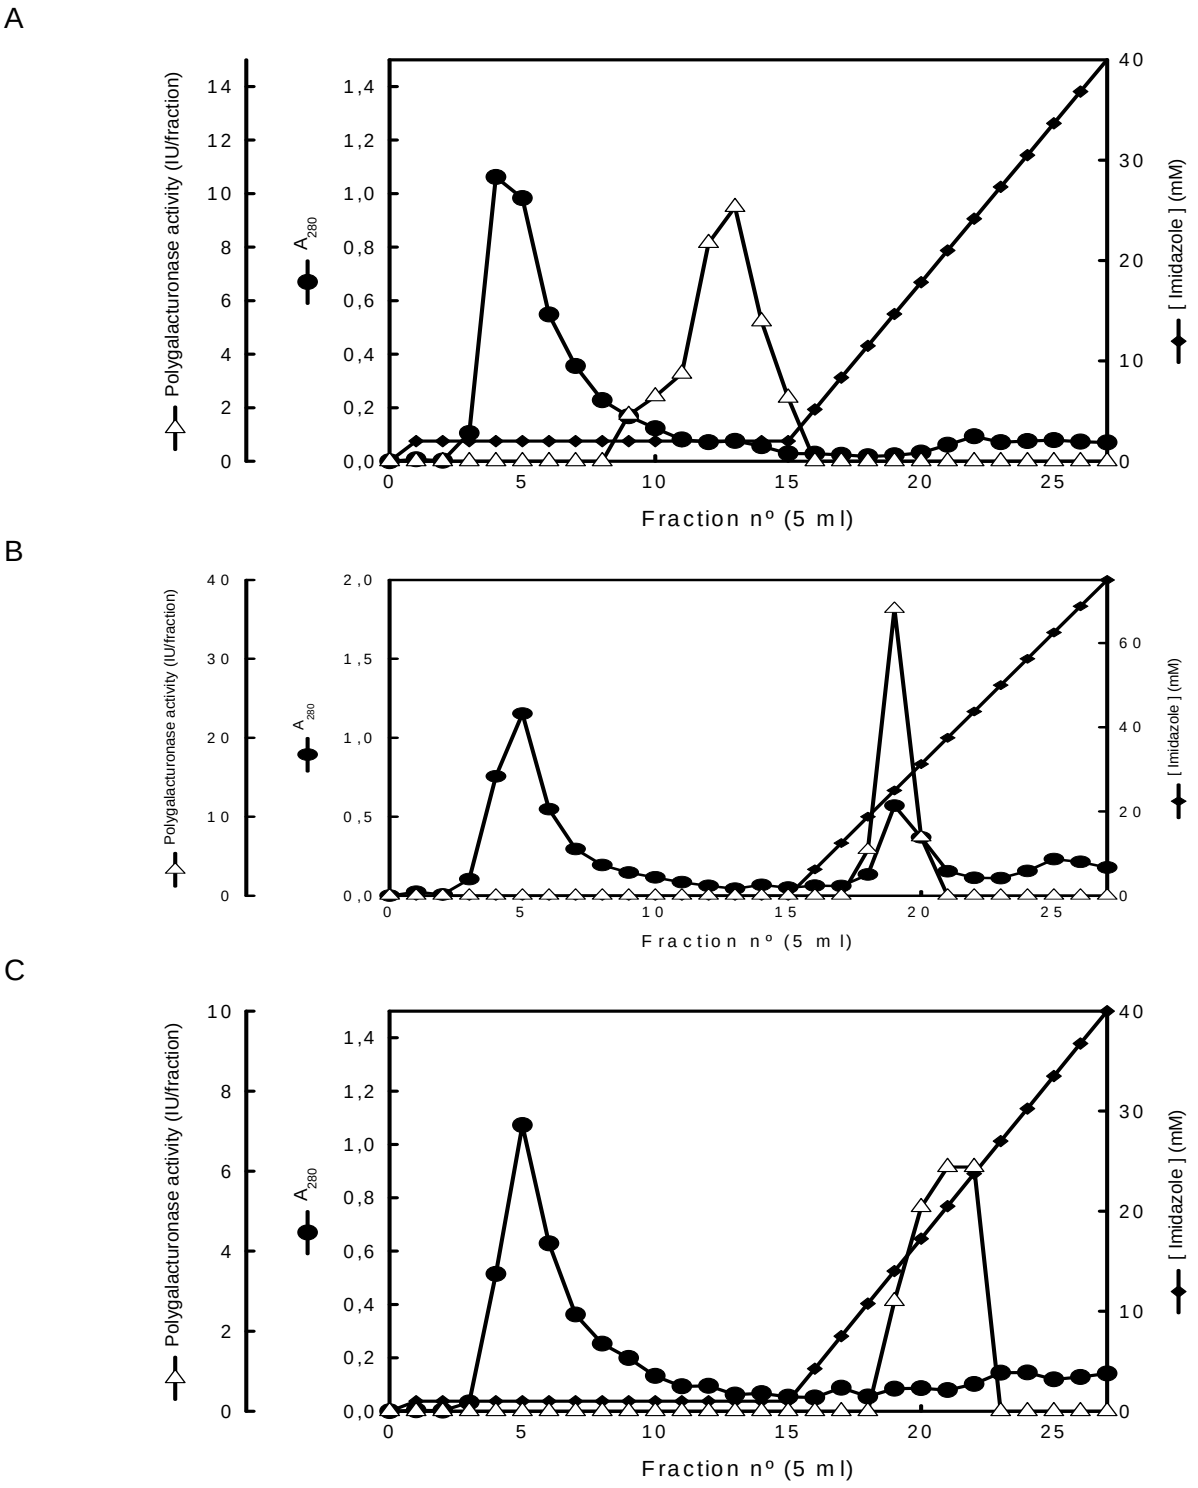

Figure 2 - Chromatographic behaviour of polygalacturonase from *P. ostreatus* on a Sepharose 6B–EPI-30–IDA-Cu(II) column at pH 6.0, as described in Materials and Methods. A- 2mM imidazole in the mobile phase (i.e equilibration buffer); B- No imidazole in the mobile phase and C- 1mM imidazole in the mobile phase.

3.4 Kinetic characterization of purified enzyme

The purified preparation of polygalacturonase exhibited an optimum pH of activity at pH 7.0, in both MES and citrate buffer. On the other hand, the optimum temperature of activity for this enzyme

was found to be at 50ºC in MES buffer at pH 7.0. As far as literature is concerned, in general, fungal polygalacturonases exhibited optimum pH in the acidic range of 3.8 – 4.6 and optimum temperature in the range of 40-60˚C. Therefore, polygalacturonase from *P. ostreatus* exhibited a higher optimum pH of activity than other enzymes from different microbial sources and moreover it is catalytically active at slightly alkaline pH which may be of great advantage for some industrial applications of this enzyme in biocatalysis.

The thermal stability of the purified enzyme was investigated at 50ºC both in citrate buffer at pH 6 as well as in MES buffer at pH 7 which revealed half life ($t_{½}$) values of 60 ± 7.45 min and 35 ± 0.37 min, respectively. These data are within the values reported in the literature for fungal polygalacturonases.

The kinetic parameters (V_{max}, K_m, K_{cat}, and K_{cat}/K_m) of the purified enzyme were found to be 5530.8 ± 260.7 U/mg of protein, 13.23 ±2.79 mg/ml of polygalacturonic acid, 5553.01 ± 261.7 s^{-1} and 419.72 $s^{-1}.mg^{-1}$, respectively at 50˚C in MES buffer and pH 7. The Km values for polygalacturonic acid for the enzymes from *Aspergillus níger* are usually lower in the range of 0.15 - 7.2 mg/ml whereas polygalacturonases from other fungal strains exhibited higher values, namely 5.77 and 11.55 mg/ml from *Sclerotium rolfsii* and 2.3 mg/ml from *Trichosporon penicillatum* SNO-3. As far as V_{max} values are concerned, a range of 828 - 24900 IU/mg protein have been reported in the literature for the enzyme from *Aspergillus níger* and *Trichosporon penicillatum,* respectively.

Keywords*:* Procyanidins, DPn, FT-IR spectroscopy, O-PLS, PLS1, grape seed.

Topic: Integration of life sciences & engineering.

Abstract

In this work, procyanidins were extracted with methanol and acetone/water from seeds of white and red grape varieties. A fractionation by graded methanol/chloroform precipitations permitted to obtain 28 samples that were characterised using thiolysis as pre-treatment followed by HPLC-UV detection; and by FT-IR spectroscopy within the region of 1300-800 cm^{-1}. By applying Orthogonal Projection to Latent Structures (O-PLS) as a generic data pre-treatment in tandem with a PLS1 regression, a robustness model for the prediction of the DPn of procyanidins is presented.

1. Introduction

Grape seeds are known as an abundant rich source of procyanidins formed by both (+)-catechin and (-)-epicatechin monomers (Escribano-Bailon et al., 1992), as well as by more polymerized fractions containing type-A and type-B procyanidin linkages (Passos et al., 2007) (**Figure 1**).

* Corresponding author. Tel + 351-234-401549. E-mail: cpassos@ua.pt

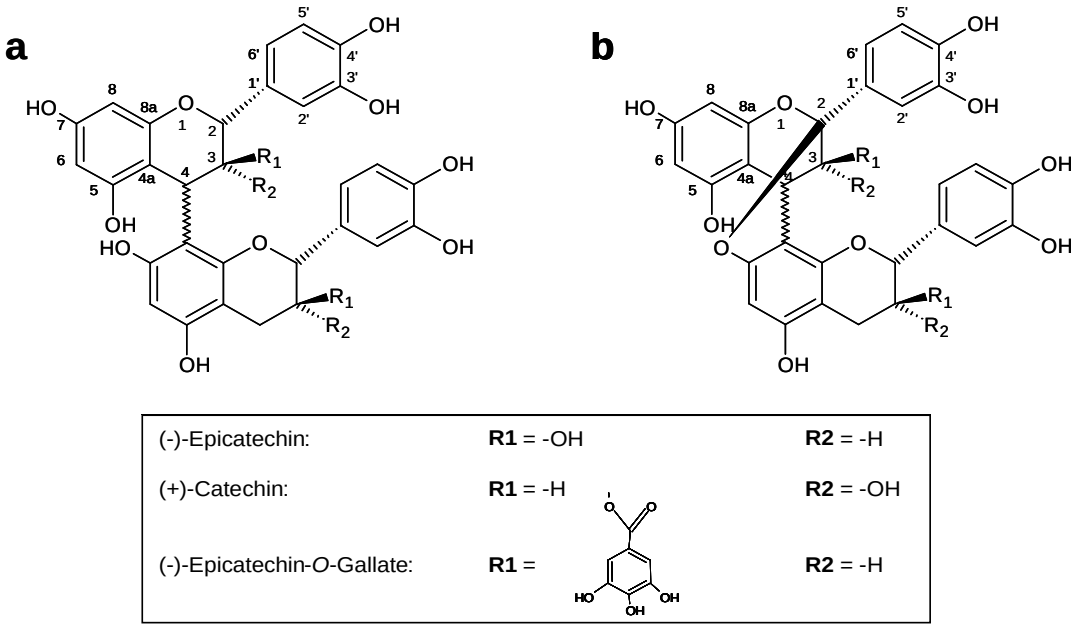

Figure 1. Structure of procyanidin dimers: (a) type-B,containing (C4-C8) interflavanic linkage and (b) type-A containing (C4-C8) interflavanic linkage (Passos et al., 2007).

Although the polymerized fractions represent more than 70% of all procyanidins, they have been only easily quantified up to tetramers (Monagas et al., 2003) . The interest upon the knowledge of their degree of polymerization has influenced the application of conventional experimental methods to assess them. For the calculation of DPn, the polymerized compounds are converted into monomers corresponding to the terminal and extension composing units of the polymer. This calculation however, is complex as it relies in previous preparation methods, (the most commonly used based on acid-catalysed degradations in the presence of nucleophilic agents), followed by characterization on reverse-phase HPLC with UV detection at 280nm (Guyot et al., 1998).

At the same time, growing interest is focused upon the development of faster, cheaper and cleaner methodologies. Nowadays, infrared spectroscopy appears as a very useful tool to accomplish a rapid evaluation, being a widespread technique in food components. Chemometric methods allow the extraction of useful information from high complex samples, among which the multivariate regression methods are widely used to build calibration models. Partial Least Squares (PLS) regression (Wold et al., 1983) is one of the most adopted. The PLS algorithm is based on a bilinear model, where the information contained in the *X* data matrix is projected over a small number of "latent" variables known as PLS components. The interpretation of the relationships between the *X* and *Y* data is simplified to the relationships between the smaller number of PLS components (Barros et al., 2004), (Guillen et al., 2005).

2. Experimental

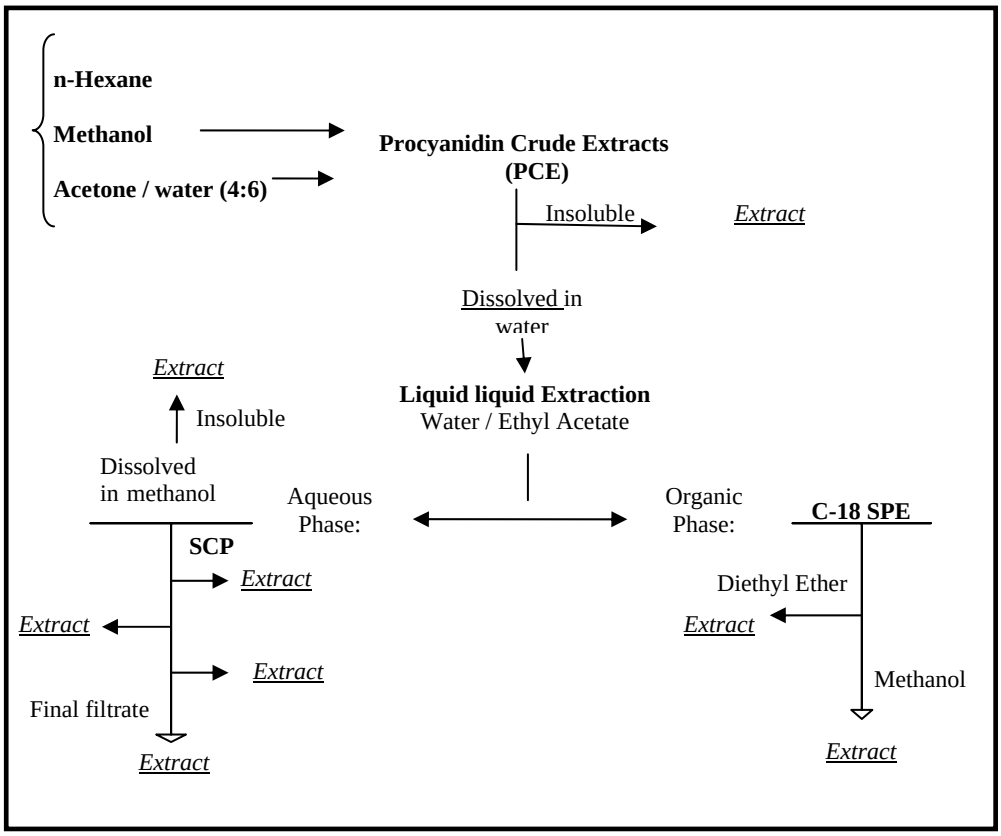
2.1. Plant Material.

Seeds were collected from grapes (*Vitis vinifera* L.) of the white variety 'Chardonnay' at technological maturity, in Bairrada Appellation, from an experimental vineyard (Estação Vitivinícola da Bairrada, Anadia, Portugal), during transfer of the musts for wine fermentation.

A mixture of red grape varieties 'Touriga Nacional', 'Touriga Francesa' and 'Tinta Roriz', were also provided by wine producers of Adega Cooperativa de Pinhel (Pinhel, Portugal). The remaining pulp and skins were separated from seeds by decantation and sieving (pore size <2.8 mm diameter). The seeds were then submitted to several wash cycles with water (200 g/L) under gentle stirring with a magnetic bar at 4 ºC during a minimum of 3 days, with two water exchanges a day, until a minimum turbidity was constant, assuring that no remaining adherent tissues were present. The purified seeds were then washed with ethanol, air dried at room temperature, and stored at 4 ºC until further analysis.

2.2. Procyanidin Extracts.

Seeds were immersed into liquid nitrogen, milled in a domestic coffee mill and sieved (pore size <0.75 mm diameter). The extraction methodology was adapted from Guyot et al., (1998), followed by a methanol/chloroform graded precipitations according to the proposed by Saucier et al., (2001) and presented in **Scheme 1**.



Scheme 1- Extraction and fractionation of grape seed flavan-3-ols. SPE: Solid Phase Extraction; SCP: Sequential Chloroform Precipitations.

Seed powder was extracted three times with *n*-hexane to remove the lipids. It was then treated three times with methanol containing 5% acetic acid to extract the phenolic compounds. The phenolic extracts were combined and filtered through a G3 sintered glass filter, and rotary-evaporated under vacuum at 40 ºC. The resultant concentrated aqueous solutions were submitted to the same treatment as for the methanol extraction but now using 5% acetic acid in an acetone/water (4/6) solution, combined the several parts, filtered with G3 glass filter, rotary-evaporated and freeze-dried as explained.

The PCE extracts from white and red grape seeds were then fractionated by dissolving the PCE powder (10 g/L) in 5% acetic acid. The undissolved material was removed by centrifugation and the supernatant was submitted three times to a liquid-liquid extraction with ethyl acetate, using a water/ethyl acetate ratio of 6:4 (v/v), resulting in an organic phase and an aqueous phase. The organic phase was concentrated, and submitted to a C18 solid phase extraction column (SPE-C18, SPE, Supelco-Discovery – 5g) by eluting with diethyl ether and methanol. The aqueous phase was evaporated to dryness and redissolved in methanol (10 g/L). The supernatant was submitted to successive additions of chloroform until the formation of a new precipitate, and then collected by centrifugation, rotary-evaporated and freeze-dried.

2.3. HPLC-UV analysis

HPLC analysis followed the conditions described by Peng et al., (2001). The HPLC apparatus used was from Perkin Elmer (series 200), with UV-Vis Detector (785A UV-VIS Detector). Samples were loaded at 30 ºC into a C_{18} column (LichroCart 250-4 Superspher 100 RP-18) equipped with a C_{18} guard cartridge with the same packing material equilibrated with 0.2% (v/v) formic acid (eluent A). Phenolic compounds were eluted by a gradient with 82% (v/v) acetonitrile and 0.04% (v/v) formic acid (eluent B) from 0 to 15% eluent B in the first 15 min; 15 to 16% from 15 to 40 min; 16 to 17% from 40 to 45 min; 17 to 43% from 45 to 48 min; 43 to 52% from 48 to 49 min, held isocratic at 52% from 49 to 56 min, reduced from 52 to 43% from 56 to 57 min, reduced from 43 to 17% from 57 to 58 min, and reduced from 17 to 0% from 58 to 60 min. Samples were loaded, at least, in duplicate. Peaks were detected at 280 nm and the monomers and procyanidin B2 dimer were identified by comparison of their retention times with standards. The epicatechin thioderivative was identified by comparison with the retention time of the products of procyanidin B2 dimer after thiolysis; the catechin and epicatechin-*O*-gallate thioderivatives were identified by their retention times and abundance and confirmed by analysis of their mass spectra. The average degree of polymerization was calculated as the ratio of all the flavan-3-ols units areas (thioether adducts plus terminal units) to the sum of the areas of catechin, epicatechin and epicatechin-*O*-gallate, corresponding to terminal units.

2.4. FT-IR spectroscopy and multivariate analyses

The FT-IR spectra were obtained using a Golden Gate single reflection diamond ATR system in a Bruker IFS-55 spectrometer. The spectra were recorded at the absorvance mode from 4000 to 400 cm^{-1} (mid infrared region) at the resolution of 8 cm^{-1}. Five replicate spectra (140 co-added scans) were collected for each sample. The measured spectra were transferred via a JCAMP.DX format into the data analysis software developed in the Institut National Agronomique Paris-Grignon in collaboration with the University of Aveiro (1999). The multivariate calibration was applied in the 1300-800 cm^{-1} region. Each spectrum was previously SNV (Standard Normal Deviates) corrected.

In order to build the calibration model for the quantification of DPn parameter a Monte Carlo cross-validation (Xu and Liang, 2001) framework was used. The dataset was split into a calibration (learning set) and a validation (external) set to assess the predictive power of the DPn model. The dimensionality of the calibration model was assessed by internal-cross validation at each iteration level, with the leave-5-out procedure. Then these models were used to predict the parameters of interest from the external set, expressed as root mean square error of prediction (RMSEP).

3. Results and discussion

3.1. Characterisation of grape seed procyanidin extracts

The dataset of procyanidin samples used in this study were composed by 28 samples from seeds of white and red grapes. The flavan-3-ols samples are constituted by monomers of catechin, epicatechin and epicatechin-*O*-gallate, and procyanidins (oligomers, and polymers) with the same constituting units. The samples, resulting from the fractionation process (according to the **Scheme 1**), resulted in a range of DPn from 1 to 11; while the chloroform graded precipitations (apparently related to a decrease in the DPn range) decreasing from DPn 10 to 1 with increasing chloroform percentage in the precipitation scheme. The region to be considered for the flavan-3-ols characterization, is represented as the region between 1300-800 cm^{-1} were substitution of the aromatic ring appears (Ramos-Tejada et. al., 2002).

3.2. Calibration models for procyanidin DPn in grape seed extracts

Using the 1300 and 800 cm^{-1} region of the FT-IR spectra, a PLS1 regression procedure has been applied to 140 FT-IR spectra (five spectra per sample) of procyanidin rich extracts for the estimation of DPn. It was necessary to have a calibration model with 12 Latent Variables (LVs), using an internal-cross validation (leave-5-out) procedure, to have a predictive power of the model using the PLS1 for the estimation of the DPn parameter. However, the relative high number of LVs introduces difficulties in the interpretation of the **b** vector profile, which may reveal a weakness of the model In these cases, it is a common approach to use different data pre-treatments to reduce the effect of variability non related to the factor of interest. One of the most powerful data pre-treatment used for removing unwanted variations is the O-PLS (Orthogonal Projections to Latent Structures) (Trygg, 2002). It resulted in a predictive O-PLS1 model with 1 LV, giving a RMSECV of 14.0%, with a R^2 of 0.89 and a RMSEP of 2.1. The final results exhibit a good linear relationship as Figure 2 points out, where the relationship between measured and estimated DPn values is plotted.

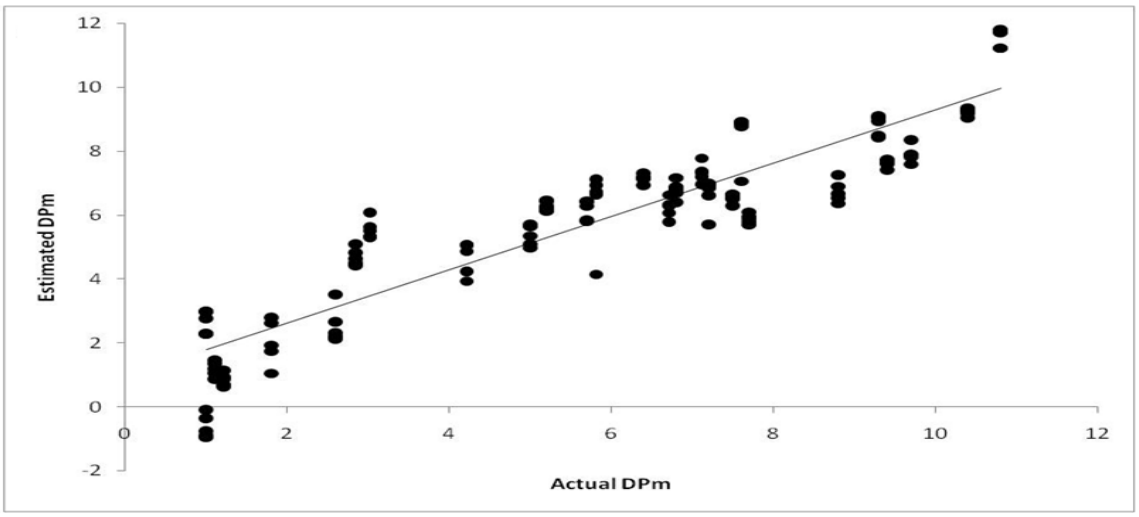


Figure 3-: Relationship between measured *versus* estimated DPn values (Regression model using O-PLS).

4. Concluding remarks.

The need for testing fast and cheap but reliable methodologies has been the base of the present work. The fractionation methodology gave the number and representative samples required to build a FT-IR model for the DPn determination. Using the resulting calibration curve it is possible to characterize grape seed procyanidins in terms of DPn.

Keywords: Chromatographic matrix; *p-tert*-butylcalix[6]arene; polymer; purification of hemoglobin; human erythrocytes; pseudoactivity of peroxidase.
Topic: Integration of life sciences & engineering.

ABSTRACT

Calixarenes are host molecules which exhibit molecular recognition towards a wide range of guest bioactive substances such as amino acids, proteins and carbohydrates. Calix[n]arenes consist of cavity-shaped architecture which can form host-guest complex with a wide range of guest molecules by introducing several functional groups either at the upper or lower rim.
The present work involves the use of a novel chromatographic matrix based on repeating units of *p-tert*-butylcalix[6]arene carboxylic acids for one-step isolation of haemoglobin from human erythrocytes. The red cell lysate was applied to a column packed with this matrix which was previously equilibrated in phosphate buffer. The adsorbed proteins were eluted from the column with a linear gradient of Na_2CO_3 pH 11.0 and the column fractions were analysed for protein and pseudo-activity of peroxidase. Human haemoglobin was purified in a one-step procedure with a recovery of pseudo-activity of about 35% and a purification factor of about 12. The purified haemoglobin was analysed both by SDS and native PAGE which exhibited single proteins bands with Mr of 16.0 and 61.0 kDa, respectively. Furthermore, the single protein band observed in native PAGE was coincident with the pseudo-activity of peroxidase band detected *in situ* on this gel. Protein adsorption on this novel chromatographic matrix involved several interactions such as electrostatic and hydrophobic and other parameters affected this process such as protein size, pI, pH, ionic strength and nature of buffer.

These results strongly suggest that this novel chromatographic matrix presents some advantages over other matrices as far as selectivity is concerned for protein purification.

INTRODUCTION

Calix[n]arenes are one of the major classes of macrocyclic host compounds in supramolecular chemistry, which exhibit molecular recognition towards a wide range of bioactive molecules such as amino acids, peptides and proteins, lectins, enzymes, nucleotides, saccharides and steroids. (Shimojo *et al.*, 2007 and Ludwig, 2005). These host compounds can be synthesized with a large choice of functional groups which exhibit differential affinity for guest molecules. Calixarenes are widely used in several applications namely as sensor devices, in nuclear waste treatment, as catalyst in synthetic reactions, biocatalysis and in liquid crystals (Gutsche, 1995 and Barata, 2004).

The unit operations involved in downstream processing of recombinant proteins and monoclonal antibodies are extremely expensive since they account for about 80 - 90% of total production cost. Therefore, there is a great interest to synthesize novel chromatographic

[1*] Corresponding author. E-mail: akarmali@deq.isel.ipl.pt.

matrices for protein purification in a single step with a high recovery of biological activity and purity. The complexing abilities exhibited by calixarenes has stimulated their potential use as molecular and biomolecular receptors immobilized on an existing polymeric matrix, for which appropriate grafting methods have been developed (Barata *et al.*, 2004). Therefore, the present work involves the use of a novel chromatographic matrix based on a polymer-bound acid derivative of *p-tert*-butylcalix[6]arene for one-step isolation of haemoglobin from human erythrocytes.

MATERIALS AND METHODS

Materials

The chromatographic matrix based on a Merrifield's resin containing units of acid derivative of *p-tert*-butylcalix[6]arene (Figure1) was synthesised according to procedures described previously (Barata, 2004). The blood was collected from one of the authors of this work and all other chemicals were of analytical grade.

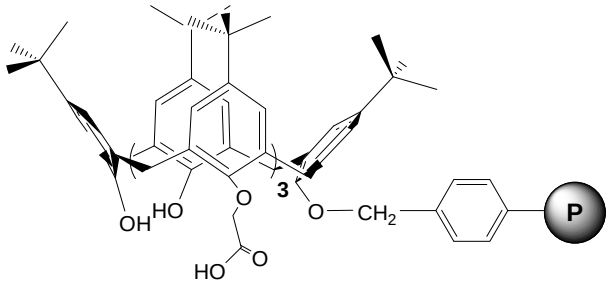

Figure 1 – Merrifield's resin containing units of acid derivative of *p-tert*-butylcalix[6]arene (PC6) structure.

Methods

Initial Treatment of Human Blood

Human blood was collected and stored at 4ºC for about 16 h. The erythrocytes were separated and washed as described by Karmali (1983) and the red cells (5 mL) were lysed with 4 volumes of deionised water and the pH of the mixture adjusted to 5.8 with 0.1N HCl and the stroma was removed by centrifugation at 15000 rpm for 30 min at 4ºC.

Purification of Hb A from human erythrocytes on Polymer-bound Acid Derivative of p-tert-Butylcalix[6]arene

Polymer-bound acid derivative of *p-tert*-butylcalix[6]arene (501 mg) was used as chromatographic matrix which was prepared by adding 6mL of $CHCl_3$. After stirring for 45 min, the solvent was removed and the chromatographic support was washed with 50 mM phosphate buffer at pH 6.5 (12 mL).

The column (1 × 5 cm) containing 2 mL of chromatographic matrix, was equilibrated with 50 mM phosphate buffer pH 6,5 (10 volumes)m and red cell lysate (diluted 1:10) was applied to the column at a flow rate of 16 mL/h. The column was washed with the same buffer system until A_{280} was less than 0,05 and adsorbed proteins were eluted from the column with 100 mM Na_2CO_3 pH 11.0, at a flow rate of 25 mL/h. The eluted fractions (0.75 mL) were collected in test tubes containing previously 50 mM citrate buffer pH 3.5 in order to adjust the pH to 7.0. The fractions were analysed for protein and pseudoperoxidase activity and those fractions exhibit enzyme activity were pooled and concentrated by ultrafiltration with a P10 membrane at 4ºC.

Electrophoretic Analysis

SDS-PAGE of red cell lysate and purified Hb A was carried out as described previously (Laemmli, 1970) and stained for protein with silver nitrate (Sasse and Gallagher, 2003).

Native PAGE of protein samples was performed as reported previously (Hames, 1990) and stained for protein with silver nitrate. The specific detection of pseudoactivity of peroxidase of Hb A *in situ* in native PAGE was carried out by using syringaldazine and hydrogen peroxide (Semedo, 2008).

Protein Assay

Protein concentration was determined by Coomassie blue dye binding method by using BSA as the protein standard (Sedmak and Grossberg, 1977).

Assay of Pseudoperoxidase Activity of Hb A

The pseudoperoxidase activity of Hb A was assayed by using syringaldazine (Syr) and H_2O_2 as substrates as described previously (Renaldo *et al.*, 1981 and Goldberg *et al.*, 1983). The assay of pseudoactivity of Hb A was carried out by using 15 μL of 1mM Syr dissolved in ethanol, 3 μL of 0.8mM H_2O_2, 262 μL of 50 mM phosphate buffer pH 6.5 and 50 μL of Hb A samples. The enzyme reaction was followed in a microtiter plate reader (Bio-Rad 680) at 550 nm due to oxidation of Syr to corresponding quinone at room temperature. One enzyme unit is defined as the amount of Hb A required to convert one μmole substrate into product per min under these experimental conditions.

RESULTS AND DISCUSSION

Hb A from human erythrocytes was purified in a single step procedure on a column packed with PC6 chromatographic matrix. The protein was desorbed from the column with 0.1 M Na_2CO_3 pH 11 (Figure 2) since buffers with neutral pH were not effective as elution agents (data not shown).

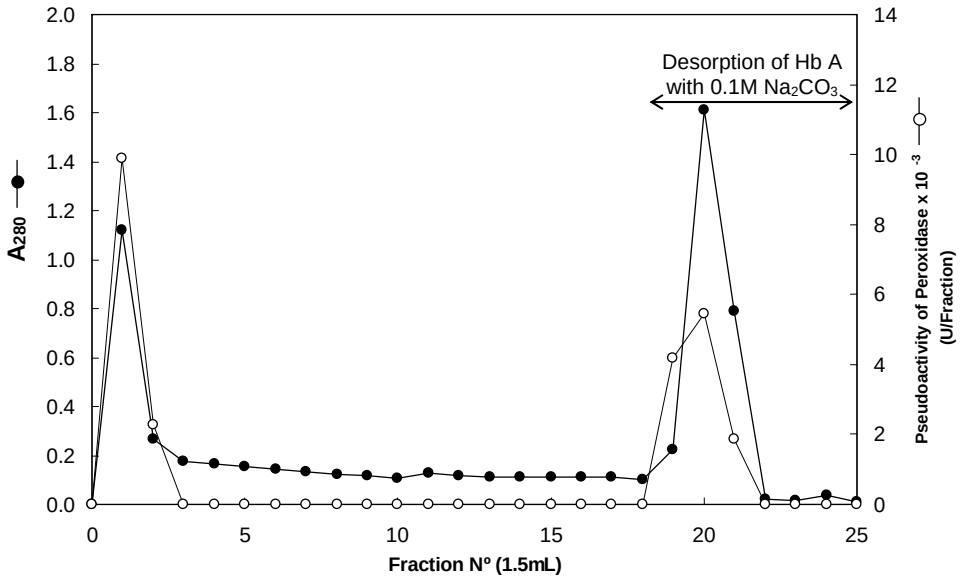

Figure 2 – Purification of Hb A from human erythrocytes, applied to a column packed with PC6.

Hb A was purified human red lysate with a final recovery of enzyme activity of about 40%, specific activity of 0.06 U/mg protein and a purification factor of 33 (Table 1).

Table 1 – One-step purification of Hb A from human blood by using a chromatographic matrix of polymer containing units of acid derivative of *p-tert*-butylcalix[6]arene.

PURIFICATIONS STEPS	TOTAL PROTEIN (mg)	TOTAL ACTIVITY (U)	SPECIFIC ACTIVITY (U/mg protein)	RECOVERY (%)	PURIFICATION FACTOR
1. Blood lysate	16.45	3.00×10^{-2}	1.82×10^{-3}	100	1
2. Column eluate	0.19	1.14×10^{-2}	6.00×10^{-2}	38	33

However, significant pseudoperoxidase activity was detected in washing fractions which suggests saturation of the chromatographic matrix. On the other hand, the purification factor obtained in the present work is apparently high since Hb A represents about 75% of total red cell protein. This discrepancy may be due to the fact that the purification factor was calculated as a function of pseudoperoxidase activity of Hb A and not as a function of Hb A concentration as reported in most of research work on Hb A in the literature. Therefore, these data may be explained by either of the following phenomenon or a combination of several factors: a - pseudoactivity of Hb A in red cell lysate may be inhibited due to the presence of metabolites in human erythrocytes; b - HbA may exhibit changes in conformation in red cell lysate with low peroxidase activity and c - the desorption of Hb A from column promoted changes in conformation of the protein which may enhance the pseudoactivity of Hb A compared with red cell lysate.

Based on these explanations, the specific activity of peroxidase of Hb A in red cell lysate exhibited a low value which resulted in a high purification factor (Table 1). Inhibition of enzymes or monoclonal antibodies either in cell-free extract or red cell lysate has been reported by several research workers (Karmali, 1983, Cruz, 1995 and Martins *et al.*, 2007).

As far as data presented in Table 1, it is not possible to compare this data with the literature because there are no reports of purification of Hb A from red cell lysate by using pseudoperoxidase activity of Hb A.

The purified Hb A was analysed by SDS-PAGE which revealed a single protein band with a Mr of 16 kDa which represents the Mr of Hb A subunits (Figure 3). However, native PAGE exhibited a single protein band with a Mr of 58 kDa which was coincident with peroxidase activity band *in situ* (Figure 4).

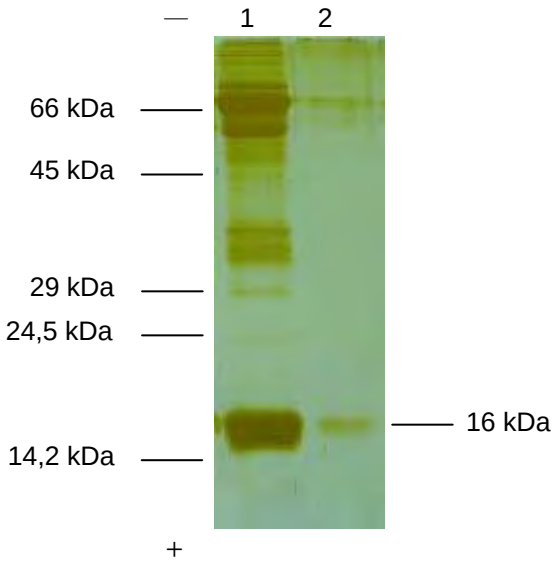

Figure 3 – SDS-PAGE of purified Hb A using a 12.5% separating gel. Lanes: 1 – Lysate blood (14.7 μg); 2 – Fractions Nº 19 to 21 (1.7 μg). The molecular weight of protein markers are presented on the left margin.

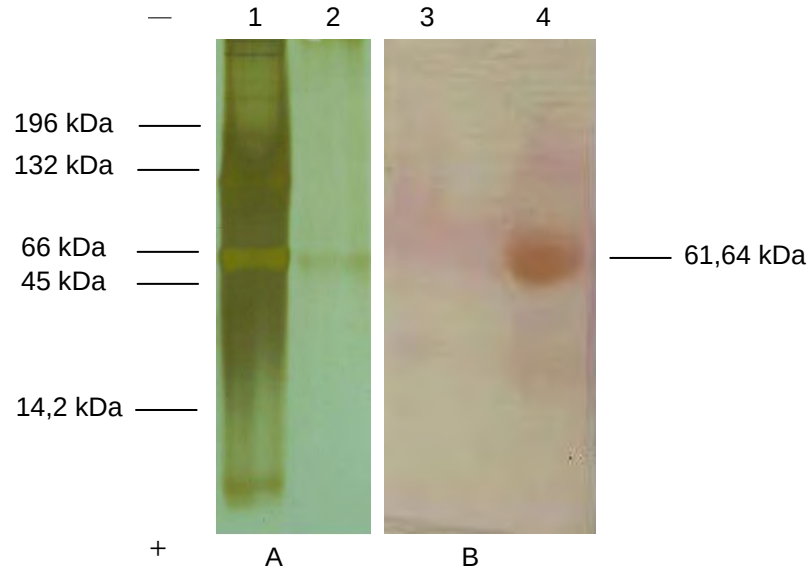

Figure 4 – Native PAGE of purified Hb A using a 7.5% separating gel. A - stained for protein with silver nitrate; B - pseudoactivity of peroxidase of Hb A *in situ*. Lanes: 1 – Lysate blood (3.7 μg); 2 – Fractions Nº 19 to 21 (1.7 μg); 3 - Fractions Nº 19 to 21 (1.67 μg); 4 - Lysate blood (52.8 μg). The molecular weight of protein markers are presented on the left margin.

The results presented in this work strongly suggest that such novel chromatographic matrices are potentially useful as far as protein purification is concerned.

Topic: biochemical engineering.

Abstract

In this research, we examined kinetic resolution of *rac*-epoxides by epoxide hydrolase from *Rhodotorula glutinis* for preparing enantio-pure diol in the presence of organic solvent. Epoxide hydrolase from *Rhodotorula glutinis* ATCC 201718 shows high catalytic activity without being extracted from whole cells, and good enantioselectivity for R-enantiomer was confirmed. The experimental data was explained well by Michaelis Menten model, including distribution of substrate and product inhibition. We examined the effect of organic solvent, initial reaction rates were correlated with the hydropohbicity of organic solvent and enatiometric ratio were correlated with the solubilty parameter. We succeed to improve enantiomeric exess by using inhibition effect of 1-heptanol. These results show possibility of preparing enantiopure diol without complicated chemical treatment.

1 Introduction

Epoxides and diols are important intermediates for pharmaceutical and organic synthetic chemistry, because each enantiomer shows different biological activity. The preparation method for enantiopure epoxides is composed to asymmetric synthesis and kinetic resolution. For the production of enantiopure epoxides, some chemocatalytic and biocatalytic routes have successfully been developed. Recently enzymatic enantioselective degradation of racemic epoxides using epoxide-hydrolases, which are relatively cheap, has been recognized as an alternative to these synthetic routes. The productivity of this biocatalytic route is limited by the low solubility of hydrophobic epoxides to aqueous solution and inhibition of enzymatic reaction at high diol concentration. To resolve these problems, the organic solvent forming two-liquid phase has been used. Decane and octane were selected in resolution of 1,2-epoxyhexane (Choi *et al*., 1999) and styrene oxide (Baldascini *et al.,* 2001), respectively.
In this paper, we examined the kinetic resolution of racemic 1,2-epoxyhexane under the two-liquid phase system. We described the kinetic analysis of this system using dodecane and examined the effect of organic solvent on the initial reaction rate and enatiometric ratio, *E*.

2 Experimental

The yeast, *Rhodotorula glutinis* ATCC201718, was cultivated for 48 h in the medium described previously (Choi *et al.*, 1999) at 30ºC. The cells were harvested by centrifugation and washed with the buffer. Hydrolysis of 1,2-epoxyhexane was conducted in screwed capped bottles sealed with rubber septa. Ten ml cell suspension of *R. glutinis* (0.9 g-drycell/ml) and 10 ml organic solvent containing 1,2-epoxyhexane were added in the bottles. Samples were taken periodically from the organic and aqueous solutions. Organic samples were analyzed by chiral GC. Aqueous samples were extracted with an equal volume of ethylacetate and then analyzed by chiral GC.

3 Results and discussion

Figure 1 shows typical results of the time-courses of epoxides and diols in the presence of dodecane. It clearly appeared that *R. glutinis* prefentially hydrolyzed (R)-epoxide and produced (R)-diol.

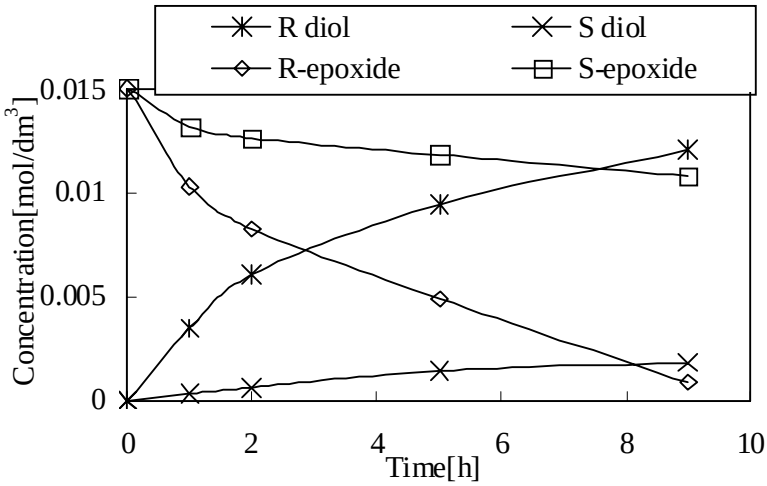

Figure 1 Kinetic resolution of *rac*-1,2-epoxyhexane by *Rhodotorula glutinis* in the presence of n-dodecane

3.1 Kinetics of hydorlysis of 1,2-epoxyhexane in the presence of dodecane

Rates of the enzymatic conversion of both enatiomers in the aqueous solution can be described as equations (1) and (2) by considering competitive Michaelis-Menten kinetics and competitive product inhibition in the view of distribution equilibrium of epoxides.

$$r_{R_0} = \frac{{V_{\max}}^{R}[R]_0}{(1+D){K_m}^{R} + \left(1+\frac{{K_m}^{R}}{{K_m}^{S}}\right)[R]_0 + (1+D){K_m}^{R}\left(\frac{[D_S]_0}{{K_I}^{D_S}} + \frac{[D_R]_0}{{K_I}^{D_R}}\right)} \quad (1)$$

$$r_{S_0} = \frac{{V_{\max}}^{R}[S]_0}{(1+D){K_m}^{S} + \left(1+\frac{{K_m}^{S}}{{K_m}^{R}}\right)[S]_0 + (1+D){K_m}^{S}\left(\frac{[D_S]_0}{{K_I}^{D_S}} + \frac{[D_R]_0}{{K_I}^{D_R}}\right)} \quad (2)$$

We determined the parameters included in above equations by kinetic experiment in the absence and presence of diols in the initial organic solution, and distribution experiment and parameters obtained were shown in Table 1. Unlike in the case of hydrolysis of styrene oxide by *Agrobacterium radiobacter* AD1 (Rink and Janssen, 1998), preference of (R)-enantiomer was caused by the large difference in the maximum velocities of enatiomers.

Table 1 Kinetic parameters

Parameter	Value
${V_{max}}^{R}$	3.41×10^{-2} mol $dm^{-3}h^{-1}$
${V_{max}}^{S}$	1.20×10^{-3} mol $dm^{-3}h^{-1}$
${K_m}^{R}$	6.90×10^{-3} mol dm^{-3}
${K_m}^{S}$	4.25×10^{-3} mol dm^{-3}
${K_I}^{D_R}$	1.80×10^{-2} mol dm^{-3}
${K_I}^{D_S}$	7.33×10^{-1} mol dm^{-3}
D	36 -

3.2 Effect of organic solvents on the reaction rate and enatiometric ratio

We examined the effect of organic solvents on the initial velocities of (R)-enatiomer, r_{R0} and enantiometric ratio, *E*.

Figure 2 shows the relationships between r_{R0} and log *P* of organic solvents. The more hydrophobic solvents, such as dodecane, isooctane gave the higher reaction rate. Hydrophilic alcohols such as hexanol, heptanol were storongly inhibitory to epoxide hydrolase of *R. glutinis*.

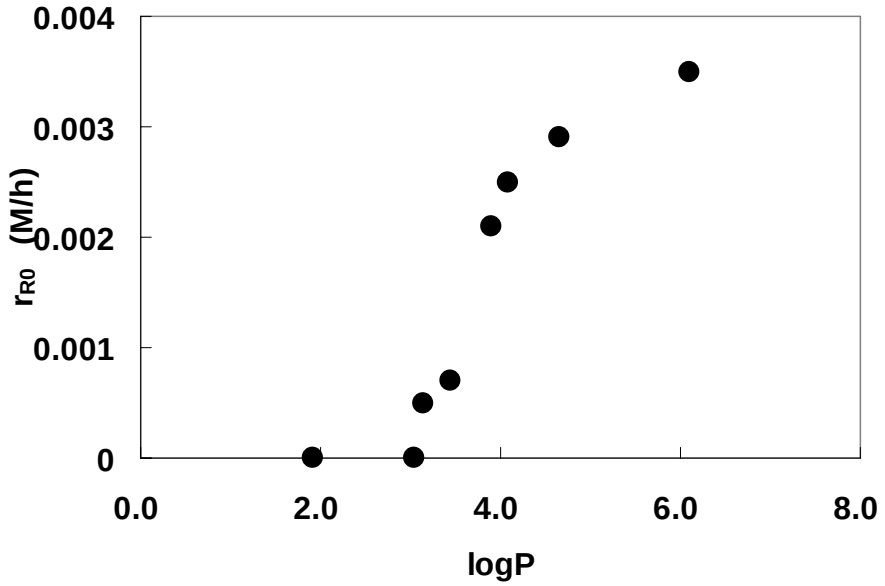

Figure 2 Relationship between r_{R0} and log *P* of organic solvent

Figures 3 shows the relationships between enatiometric ratio *E* and solubility parameters. Enationmetric ratio is defined as following equation.

$$E = \frac{\ln\left[1-\zeta\left(1+ee_p\right)\right]}{\ln\left[1-\zeta\left(1-ee_p\right)\right]} \qquad ee=\frac{R-S}{R+S} \tag{3}$$

where *E* is enantiomeric ratio, ζ is yield, *ee* is enantiomeric exess , and R and S are concentrations of *R*- and *S*- enantiomers, respectively. Solubility parameter δ provides a numerical estimate of the degree of interaction between the solvents and 1,2-epoxyhexane(δ=9.18). Solvents having high solubilty parameters such as higher alcohol, carboxylic acid did not give the high enatioselectivity because of the strong interaction between the solvent and substrate.

For the further improvement of the enantiometric ratio, we examined the effect of addtion of inhibitory compound, 1-heptanol, on the kinetic resolution in the presence of dodecane. Figure 4 shows the relationship between initial production rate of (R,S)-1,2-hexanediol and sustrate concentration. Control denotes the experiment in the presence of dodecane. By adding 1-hexanol (0.017 mol/dm^3), initial production rate of R-1,2-hexanediol a little bit reduced, while it was not detected S-1,2-hexanediol in the reaction mixture, indicating that enatiometric ratio is infinitely large.

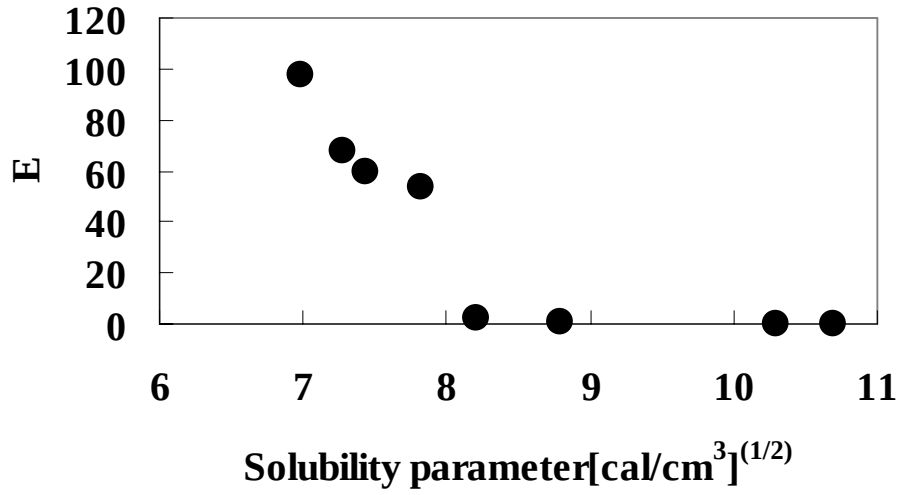

Figure 3 Relationship between enatiometric ratio *E* and solubility parameter of organic solvent

Keywords: Hydrogels, polyvinyl alcohol, immobilization of enzymes and cells, biotransformations, encapsulation
Topic: Integration of life sciences & engineering.

Abstract

Inulinase, penicillin G acylase, cutinase, *Mycobacterium* sp. NRRL B-3805 and *Rhodococcus erythropolis* DCL14 cells were immobilized in PVA-based hemispherical-shaped capsules, obtained through extrusion into polyethylene glycol, according to a novel method. The immobilized biocatalysts obtained were tested for sucrose hydrolysis, penicillin G hydrolysis, caproic acid esterification with ethanol, sitosterol side-chain cleavage and limonene-1,2-epoxide hydrolysis, respectively. The effect of immobilization in overall biotransformation rate was assessed, as well as the feasibility of biocatalyst reuse. Mass transfer and partition effects were evident upon immobilization, more so in the three latter systems, where an organic phase was used as substrate reservoir/product sink. Immobilized inulinase and penicillin G acylase were effectively reused in 10 consecutive batch runs with no noticeable decay in performance. In the remaining systems tested decay of activity was observed, more noticeably in whole cell systems, as immobilized cutinase was effectively used in three consecutive runs.

Hydrogels are suitable materials for biocatalyst immobilization and concomitant application in biotransformation systems of relevance in important industrial areas, such as food and feed, pharmaceutical, fine chemicals, renewable energy sources and bioremediation (Guisan, 2006). Hydrogels typically present biocompatibility, low coefficient of friction, and high water content. Still, most hydrogels, namely those from natural polymers, have low mechanical stability (Willaert and Baron, 1996) and are furthermore prone to enzyme leakage (Cao, 2005). Polyvinyl alcohol-based matrices have been shown to lead to particles with considerable mechanical stability, and thus present a suitable alternative to overcome the drawbacks of natural polymers while retaining the benefits inherent to their use (Schlieker and Vorlop, 2006). Several methods have been developed to form hydrogels from polyvinyl alcohol (PVA). In the present work a modified procedure for the encapsulation of biocatalysts in PVA capsules from LentiKats® liquid (GeniaLab, Germany) is presented. In this method, the PVA based hydrogel is extruded to low molecular weight polyethylene glycol (PEG) or polypropylene glicol (PPG), where gelification occurs instantaneously, in the form of spherical-like capsules. The procedure is quite simple and the PEG or PPG can be recycled for several times. The feasibility of the method was evaluated through immobilization of enzymes (cutinase, penicillin acylase, inulinase) and whole cells (*Mycobacterium* spp. and *Rhodococcus* spp.), currently used in our laboratory, and the resulting biocatalysts were tested in their corresponding applications. These include sucrose hydrolysis (inulinase), penicillin G hydrolysis (penicillin acylase), and esterification of caproic acid with ethanol (cutinase), sitosterol side-chain cleavage to

yield androstenedione, AD (*Mycobacterium* spp.) and conversion of limonene-1,2-epoxide to limonene-1,2-diol (*Rhodococcus* spp.) No enzyme leakage was observed, during immobilization procedure, even for the low molecular weight cutinase (21 kDa), although during bioconversion runs some leakage of cutinase has occured. Biocatalytic activity was maintained following immobilization, although diffusion limitations occurred. Nevertheless all immobilized biocatalysts were effectively used in aqueous or organic media, if the latter was more appropriate. PVA capsules maintained their integrity even in the presence of magnetic stirring and immobilized inulinase and penicillin acylase were used in consecutive batch runs without activity loss. A decrease in activity was observed when immobilized cutinase was used along five consecutive runs. A marked decay in activity was observed when either of the immobilized cell systems was reused. Since a similar decrease was observed for free cells, this could be ascribed to intrinsic loss of catalytic activity and not to biocatalyst leakage

The method developed proved nevertheless promising, particularly for applications in aqueous systems, since it displayed favorable mass transfer and partition features. In the overall it is quite easy to implement, is relatively cheap and can be easily scaled-up, thus providing a suitable alternative to currently used approaches

2 Materials and methods

Fructozyme L, a commercial preparation of inulinase from *Aspergillus niger*, penicillin G acylase (PGA) solution (26.6 mg ml^{-1}) from *Escherichia coli* were obtained from Sigma, *Fusarium solani pisi* cutinase wild-type was produced by recombinant *S. cerevisiae* SU50 strain as described by Calado and co-workers (Calado et al.,2002). *Mycobacterium* sp. NRRL B-3805 cells with sitosterol side-chain cleavage activity were obtained as described elsewhere (Staebler et al, 2004). *Rhodococcus erythropolis* DCL14 present a limonene epoxide hydrolase activity were obtained as described by de Carvalho and co-authors (2000) Ethyl caproate and caproic acid were obtained from Sigma-Aldrich, ethanol 96 % form AGA, penicillin G was obtained from Fersinca Gb, β-sitosterol was from Acros, androstenedione (AD), and progesterone were obtained from Sigma, polyethylene glycol (PEG) 600 and polypropylene glycol (PPG) 425 and 2000 were from Fluka, LentiKat® liquid, a PVA-based material, was from GeniaLab and inulin from chicory (Fibruline Instant) was a kind gift from Cosucra. all other chemical were of analytical grade from various suppliers.

Biocatalyst immobilization

Entrapment of biocatalyst in PVA based capsules was performed as follows. The LentiKat® liquid was heated at 95ºC for melting and then allowed to cool to 35ºC - 40ºC. Individual Enzyme or whole cell preparations were added to 10 ml of the LentiKat® liquid and thoroughly mixed. The resulting liquid was extruded through a needle (Therumo, 20 G x 2'') into stirred 150 ml of PEG 600 at room temperature. In the case of inulinase immobilization, the use of PPG 425 and PPG 2000 were also evaluated. After a 2-hour period, the hemispherical capsules formed, with roughly 3 mm diameter, were harvested, thoroughly washed with adequate buffer, weighed after removal of excess buffer with qualitative filter paper, and immediately used for bioconversion runs.

Enzyme solution or whole cell suspensions added to LentiKat® liquid were as follows: for inulinase, 0.5 ml of a ten-fold, 100 mM acetate buffer, pH 4.5, diluted commercial preparation were used; for cutinase, 0.5 ml of cutinase solution (61.2 mg ml^{-1}) in 50 mM phosphate buffer, pH 7.0, were used; for PGA, 75 μL of enzyme preparation were used; for mycobacterial cells, 2.5 ml of a 400 mg ml^{-1} suspension (wet cell weight) in 100 mM phosphate buffer, pH 7.0 were used; for *Rhodococcus* cells a 200 mg ml^{-1}

suspension (wet cell weight) in mineral medium. Capsules were washed using buffer solution used in enzyme/cell preparations.

Bioconversion runs

Sucrose hydrolysis to reducing sugars was performed in 24-hour runs, in 1.5 ml screw-capped magnetically stirred reactors at 50ºC, in 1.0 ml of 100 mM acetate buffer, pH 4.5, containing 10.0% (w/v) sucrose and 50 mg of immobilized inulinase. Penicillin G hydrolysis was performed in 10 minutes runs in a small batch stirred reactor, using 5.0 g of biocatalyst and 25 ml of a 4% (w/v) penicillin solution in 20 mM phosphate buffer, pH 8.0, at 37ºC. Esterification was carried out at 30ºC, in 24-hour runs, in isooctane (containing 20 mM n-decane) as organic solvent in 10 ml magnetically stirred flasks capped with EPDM stoppers, black (Sigma.Aldrich) and filled with 7 ml reaction medium, containing 0.2 M ethanol and 0.1 M caproic acid, and 3.3 g capsules. AD production was performed in 24-hour runs, at 30ºC, in 250 rpm shaken 15 ml screw-capped cylindrical flasks, filled with 1.0 g of biocatalyst. and 5 ml of a 1:1 organic–aqueous volumetric phase ratio medium, composed of phosphate buffer and a 12 mM solution of β-sitosterol in dioctyl phthalate. The hydrolysis of limonene-1,2-epoxide to limonene-1,2-diol, with 3.0 g of immobilized *R. erythropolis* cells, was performed in magnetically stirred 100 ml cylindrical flasks closed with rubber bungs, at 30ºC, containing 20 ml of a 1:5 organic–aqueous volumetric phase ratio medium, composed of mineral medium and a 50 mM (referred to the aqueous phase) solution of limonene-1,2-epoxide in dodecane or *iso*-octane. After each bioconversion run, the immobilized biocatalysts were washed with buffer, except immobilized cutinase, which was washed with isooctane, and used for further runs. Bioconversion runs were also performed with free biocatalysts, in concentrations that matched those corresponding to the immobilized biocatalyst. Free biocatalysts were also challenged for reuse. In all cases, samples were periodically collected for substrate/product analysis.

Analytical methods

Quantification of reducing sugars formed during sucrose hydrolysis was performed by the DNS method (Miller, 1959). Quantification of penicillin G hydrolysis was performed by the pH STAT method, based on automatic pH correction. The concentration of ethanol, caproic acid, and ethyl caproate was determined by gas chromatography, in a Hewllet-Packard model 5890 gas chromatography (GC) equipped with a flame ionization detector (FID) and a WCOT Fused Silica coating CP Chirasil- Dex CB column, 25m x 0.25mm, DF=0.25 (Varian Inc.). n-Decane present in the reaction medium was used as internal standard. AD concentration was determined by HPLC as described elsewhere (Staebler et al., 2004). The concentration of limonene-1,2-diol was determined by GC (de Carvalho et al., 2000). Quantification of protein was performed by the BCA method (Smith et al., 1985) using a commercial kit from Pierce, or by monitoring of aqueous liquid phases at 280 nm.

3. Results and discussion

Hemispherical capsules with catalytic activity for sucrose hydrolysis were obtained following extrusion of PVA based liquid into both PEG 600 and PPG 425. Extrusion into PPG 2000 failed to allow the formation of stable, individualized particles. Since the former allowed for slightly higher specific activity yields (Table 1), the former polyether was chosen for further trials. No biocatalyst leakage was observed during the immobilization process (data not shown).

Table 1. Effect of polyether used for capsule formation in the relative specific activity of inulinase

Polyether	PPG 425	PPG 2000	PEG 600
Relative specific reaction rate	0.92	Capsules not formed	100

Immobilization of the biocatalyst brought along mass transfer hindrance, which were particularly noticeable when non-purely aqueous systems were used. In these systems, involving the use of relatively hydrophobic chemicals, partition effects are most likely to also have to be accounted for (Table 2).

Table 2. Effect of immobilization on the reaction rate of the different bioconversion systems trialed.

Bioconversion	Sucrose hydrolysis	Penicillin G hydrolysis	Ethyl caproate synthesis	AD production	Limonene-1,2-diol production
Relative reaction rate [a]	0.40	0.25	0.05	0.08	0.15

[a] Determined as the ratio of the specific reaction rate using immobilized and free biocatalyst

The evaluation of the effect of immobilization in the overall reaction rate of a given bioconversion system plays a significant role when assessing the feasibility of the system trialed. Along with it, the possibility of biocatalyst reuse plays also a key role, as it contributes to the economical feasibility of the process. In the different systems evaluated, PVA capsules performed best in sucrose and penicillin G hydrolysis, where several consecutive runs were performed with no decrease in product yield or in biocatalyst activity, respectively (Figure 1). A decrease in product yield was on the other hand observed for immobilized cutinase, partly due to enzyme leakage from the capsules, given some residual activity observed in the supernantant

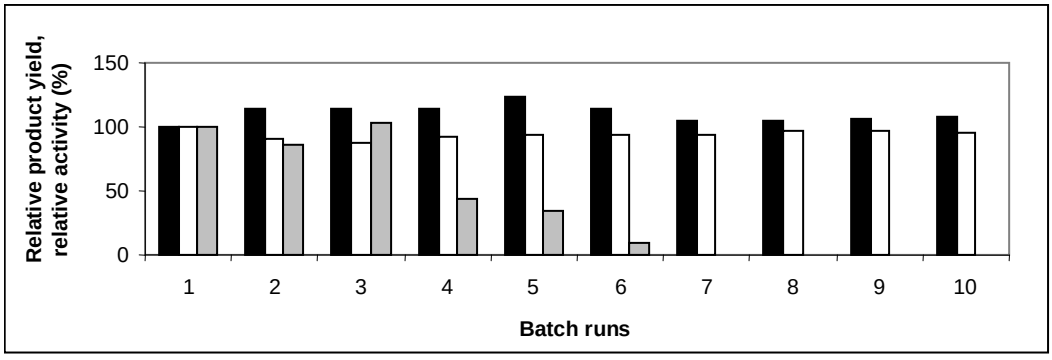

Figure 1. Effect on the final product yield and relative activity of the repeated use of inulinase, PGA and cutinase immobilized in hemispherical beads (open, closed and grey bars, respectively), for sucrose and penicillin G hydrolysis and ethyl caproate synthesis. Initial product yield for sucrose hydrolysis was of 100 g l^{-1} reducing sugars, initial activity was of 200.4 U, where U is defined as the amount of enzyme required to produce 1 μmol of 6-Amino Penicillanic Acid per minute, and initial product yield for esterification corresponded to 60% conversion yield, based on caproic acid.

As for the feasibility of reusing immobilized mycobacterial or *Rhodococcus* cells in the selected bioconversion systems, PVA capsules effectively retained biomass, particularly in the case of mycobacterial cells, although considerable loss of biocatalytic activity was observed upon reuse (Figure 2). Still a similar pattern was observed when free cells were used, which suggests that the decay of catalytic activity is an intrinsic cell feature, possible related to lack of adequate maintenance requirements, as already suggested (Fernandes et al., 1998)

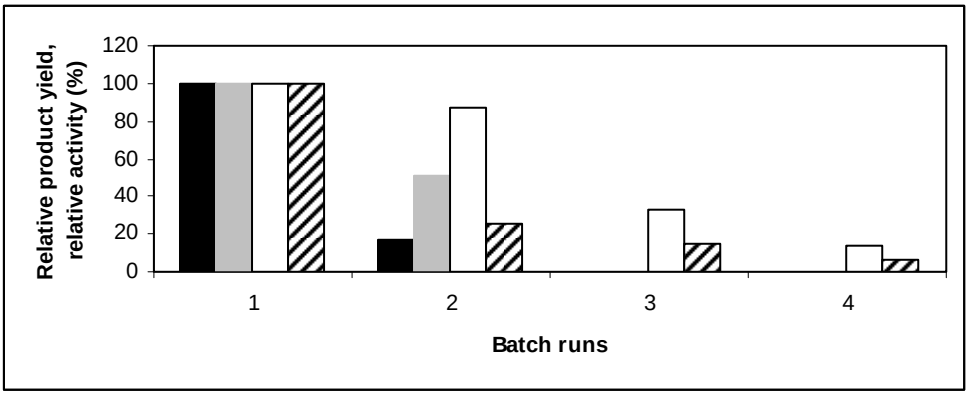

Figure 2. Effect on the final product yield and relative activity, respectively, of the repeated use of mycobacterial (open and striped bars) and *Rhodococcccus* cells (closed and grey bars) either free (closed and open bars) or immobilized in hemispherical beads (grey and striped bars) for AD and limonene-1,2-diol production.

4. Conclusions

A new methodology to obtain PVA based capsules from LentiKat® liquid was used to immobilize enzymes and whole cells, specifically inulinase, PGA, cutinase, *Mycobacterium* sp. NRRL B-3805 and *R. erythropolis* DCL14 cells. The performance of the immobilized biocatalysts was evaluated in well known bioconversion systems, by assessing the effect of immobilization on overall reaction rate and biocatalyst reuse. Promising results were obtained for inulinase and PGA, for mass transfer limitations were not most relevant and biocatalysts were effectively reused in ten consecutive batch runs. In the remaining systems enzyme and biomass were immobilized and catalytic activity retained but mass transfer limitation were significant, possibly given the hydrophobic nature of chemicals and solvents in these systems. Still, immobilized cutinase was effectively recycled in three consecutive batch runs. On the other hand, a marked decay in catalytic activity was observed, when either free or immobilized cells were reused, suggesting lack of maintenance requirements.

e-mail: aguvenc@ogu.edu.tr

Abstract

The purpose of this study was to investigate the effect of influential parameters on the recovery of citric acid from dilute solutions by using electrodialysis which is one of the effective membrane processes. The laboratory-scale experimental setup consisted of a three compartment perspex cell, a power supplier and three peristaltic pumps. The cathode and anode compartments were separated from the center compartment with ion exchange membranes. The effects of applied potential, feed solution concentration, feed flow rate and feed solution pH values on the recovery rate of citric acid, current efficiency and specific energy consumption were examined. High levels of citric acid recovery were achieved (up to 99.5%) in 270 minutes with higher current efficiency (~97%) and lower energy consumption (~6.5 kWh/kg) values. It was found that these values were obtained by applying the optimum operating conditions of 15 V, 2.6 $mL.s^{-1}$, 8 $g.L^{-1}$ and 3 as voltage, flow rate, feed concentration and pH, respectively. The results have indicated that electrodialysis is an effective method for recovery of citric acid which is already employed in the food industry.

Keywords: Electrodialysis; Citric acid; Ion exchange membranes; Current efficiency; Energy consumption.

2.1 Introduction

Citric acid (H_3Cit) is of paramount industrial importance because it is a useful product which has been widely used in dairy, medicine and biochemical industries (Chen, 1991). In particular, there is an increasing use of sodium citrate in washing formulations. Sodium citrate is used as builder and buffering agent in liquid detergents to replace the tetrapotassium pyrophosphates, which has become a global concern for the environment (Rohr et all., 1983). The production of citric acid is normally accomplished by fermentation whereby the separation from the fermenter broth is achieved by a chemical method. This traditional process causes a large amount of water effluent as well as solid residue. Electrodialysis (ED) is an environmentally friendly alternative to the technology which is currently in use. Electrodialysis has been developed not only for the recovery of useful components, but also for recycled use of water.

Voss (1986) compared three ED designs to deacidification of citric acid using both monopolar and bipolar membranes. His results indicated that ED using combination of anion-exchange membranes and bipolar membranes gave the best performance.

Xu and Weihua (2002) investigated the effect of cell configurations on the performance of citric acid production by a bipolar membrane ED and suggested the optimum cell configuration. They used three basic cell arrangements and discussed these configurations in view of cell voltages, bipolar potential drop, current efficiency and energy consumption. They suggested that the arrangement of cation exchange membrane – bipolar membrane – cation exchange membrane seemed to be the favorable cell configuration for the production of citric acid.

Nikbakht et al. (2006) investigated the effects of some influential factors such as pH, voltage, flow rate, temperature and feed concentration on the performance of an ED experimental setup by using Taguchi method. According to their final results, all factors have some effects on the response while effects of pH and voltage on the mean response are more significant than those of flow rate and temperature.

The aims of this paper were to recover the citric acid from dilute solutions using the Ionac MA-3470 and MC-3475 ion-exchange membranes, to test the separation efficiency of the ion-exchange membranes for the process and to obtain the fundamental data for the development of electrodialysis process taking the current efficiency and energy consumption into consideration.

2. Experimental

2.1 Experimental Setup

The experimental setup consisted of an ED cell, a DC power supplier, three solution tanks (each was with the capacity of 250 mL) with peristaltic pumps. The ED cell was composed of three compartments separated a pair of ion exchange membranes (cation and anion). Carbon fiber and stainless steel were used as an anod and a cathode, respectively. The experiments have been performed in batch recycle mode at ambient temperature (Hacıoğlu, 2006).

2.2 Membrane And Material

Ionac MA-3475 anion exchange membrane and MC-3470 cation exchange membrane (Sybron chemicals Inc.) were employed. The chemical and physical properties of ion exchange membranes are presented in Table 1. Effective area of each of the membranes and electrodes was 19 x 4 cm^2 while thickness of center compartment was 1 cm^2 and the thickness of each electrode compartment was 0.5 cm. All chemicals used were analytical grade.

Table 1
Main characteristics of ion-exchange membranes

	Ionac MC-3470	Ionac MA-375
Type of membrane	Cationic	Anionic
Ionic form, as shipped	Sodium	Chloride
Permselectivity	96	99
Area resistance, Ohm/cm (0,1 N NaCl)	25	50
Mullen Burst Test, min. (psi)	150	150
Temperature Stability, max. (C°)	80	80
Exchange capacity (Meq/g)	1.4	0.9
Water permeability (ml/hr/ft^2) @ 5 psi	25	25
Thickness (mils)	15	16
Chemical Stability, pH	1 to 10	1 to 10

2.3 Experimental Procedures

During all the experimental studies, 0.05 M sodium chloride solution was circulated through the electrode compartments at flow rate of 0.5 $mL.s^{-1}$ and pH of 6.5. The changes in the citric acid conc. in the feed solution tank were determined at each ten minutes and the experiments were ended when the (99±0.5)% recovery of citric acid reached. Volumetric

method was applied to determine the concentration of citric acid using 0.1 M sodium hydroxide solution. The potentiostatic mode was chosen in ED experiments taking our previous study into consideration (Güvenç and Karabacakoğlu, 2005).

The experiments can be summarized as follows:

- To investigate the effect of cell voltage, the trials were carried out at constant feed solution concentration of 8.0 $g.L^{-1}$, feed flow rate of 2.60 $mL.s^{-1}$ and feed solution pH of 3, by applying the voltages of 7.5, 15, 30 and 45 V.
- To investigate the effect of feed flow rate, the trials were carried out at constant feed solution concentration of 8.0 $g.L^{-1}$, pH of 3 and cell voltage of 15 V, by applying 1.00, 2.60 and 6.80 $mL.s^{-1}$ flow rates.
- To investigate the effect of feed concentration, the trials were carried out at constant cell voltage of 15 V, flow rate of 2.60 mLs^{-1} and pH of 3, by using the concentrations of 8 $g.L^{-1}$ and 16 $g.L^{-1}$.
- To investigate the effect of pH, the trials were carried out at the constant feed solution concentration of 8.0 $g.L^{-1}$, feed flow rate of 2.60 $mL.s^{-1}$ and voltage of 15 V, by employing the pH values of the feed solutions as 3 and 4

3. Results and Discussion

3.1 Current-Voltage Curves

The amount of ions transported through the membrane is directly proportional to the current or current density. İncreasing the current density leads to an increase in the number of ions transferred. The relation of current-voltage characteristics of the ion-exchange membrane for the different citric acid conc. was investigated. As shown in Fig.1, the current reached a plato when the lower conc. of citric acid solutions were used. This is the region of the limiting current density where all the available ions are transferred. If the ionic conc. of citric acid increased then the limiting current density increased as well but the plato value became less pronounced. When the voltage increased further, no ions are available anymore to transfer the charge and water splitting will occur to generate ions related to the overlimiting current (Mulder, 1998).

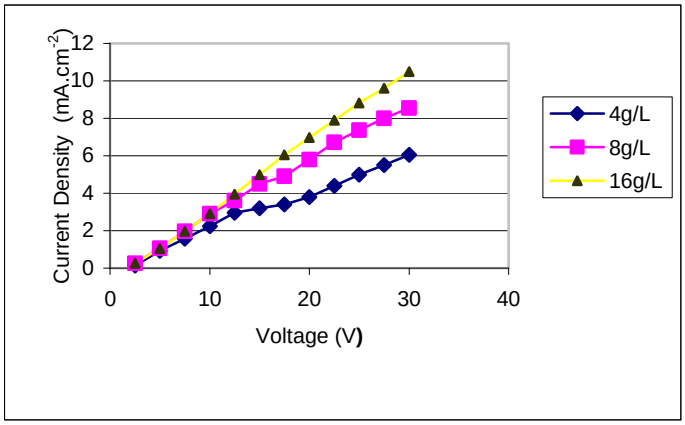

Fig 1. Experimental I-V curves at different concentrations of citric acid

To interprete the results obtained from the experimental studies, the current efficiency and energy consumptions, which were the electrochemical performance factors, were calculated and discussed.

- The current efficiency ŋ was calculated using Eq.(1)

$$\eta = \frac{(C_O - C_t)VF}{NIt} \quad (1)$$

where C_0 and C_t are the conc. of citric acid at time 0 and t, respectively. V is the circulated volume of feed solution, I the current, F the Faraday constant and N is the number of cell triplets. The current efficiency is determined by various time intervals from the beginning and therefore it is dependent of time.

- The energy consumption E (kWh/kg) was calculated using Eq. (2)

$$E = \int \frac{UIdt}{C_t VM} \quad (2)$$

where U is the potential across the cell (V), M is the molar weight of citric acid (192 $g.mol^{-1}$).

3.2 Influence of cell voltage

Cell voltage is an important parameter because it is related to energy consumption associated with the recovery of citric acid. The voltage drop, which refers to the variation taking place in the ED cell, mainly includes the Donnan Potential at all solution-membrane interface and diffusional potential both in the ion-exchange membrane and in the solution. In the study, the ranging of cell voltages were 7.5, 15, 30 and 45 regarding the relation of current-voltage curve as given in Fig. 2-3. The results obtained by applying 7.5 and 15 Volts showed that the current efficiency and energy consumption values were nearly similar in both cases. However, since the recovery of citric acid took more time in the case of 7.5 V applied voltage, the 15 V applied voltage value was chosen as optimum by considering membrane fouling. This was also supported by Fig. 1 where the available ions were transferred between the 10-20 voltages. On the other hand, the 30 V and 45 V applied voltages could not be considered as optimum values due to the lower current efficiencies and higher energy consumptions.

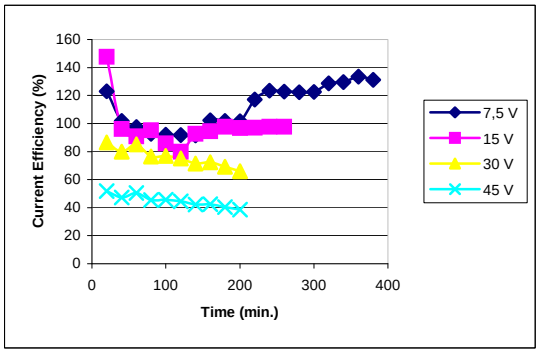

Figure 2. Variation of current efficiency with removal time for a range of applied voltages (The conc. of the feed solution: 8.0 $g.L^{-1}$; pH: 3; flow rate of solution: 2.60 $mL.s^{-1}$)

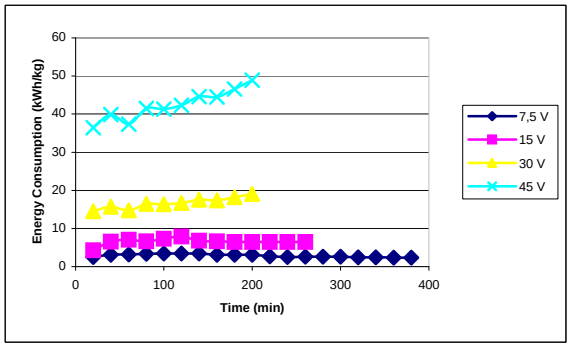

Figure 3. Variation of energy consumption with removal time for a range of applied voltages (The conc. of the feed solution: 8.0 $g.L^{-1}$; pH: 3; flow rate of solution: 2.60 $mL.s^{-1}$)

3.3 Influence of flow rate

The use of lower flow rate (1 $mL.s^{-1}$) was not advantageous for economy of treatment since it allowed the increase in the time of treatment and it may also give rise membrane fouling. (Fig.-4.5) Increasing the flow rate up to 6.8 $mL.s^{-1}$ decreased the recovery of citric acid duration due to residence time reduction. As a matter of fact, increasing the residence time is equivalent to enhancing the effective membrane contact area. From the engineering point of view, the flow rate of 2.6 $mL.s^{-1}$ can be chosen as an optimum value with higher current efficiency, lower energy consumption and also with the proper duration of ED.

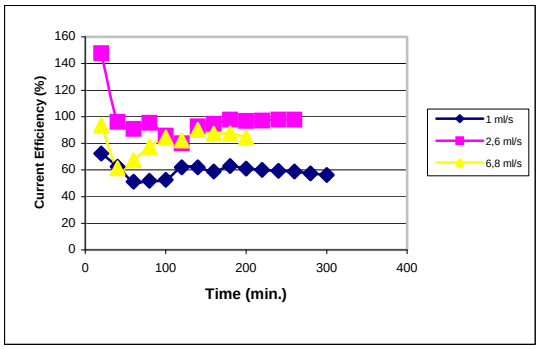

Figure 4. Variation of current efficiency with removal time for a range of applied flow rates (The conc. of the feed solution: 8.0 $g.L^{-1}$; pH: 3; applied voltage:15V)

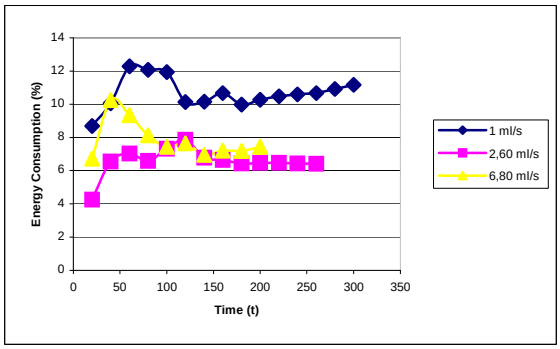

Figure 5. Variation of consumption with removal time for a range of applied flow rates (The conc. of the feed solution: 8.0 $g.L^{-1}$; pH: 3; applied voltage:15V)

3.4 Influence of feed concentration

In the case of higher conc. of feed solution, ED cell use higher current owing to the presence of higher charged ions since the solution conc. is related to the current density. The conductivity of solution increases as the solution conc. increases (resistance decrease). In this case, the electric current increases by Ohm's law. As can be seen from Fig. 6-7, when we used higher conc. of citric acid (16 $g.L^{-1}$), lower current efficiency and higher energy consumption were obtained according to the Eq. 1 and 2 and the duration of ED reached 100 min. After this time, the variation of current efficiency and energy consumption showed similar trends for both higher and lower conc. of citric acid due to the decreasing of conc. diference between the solutions.

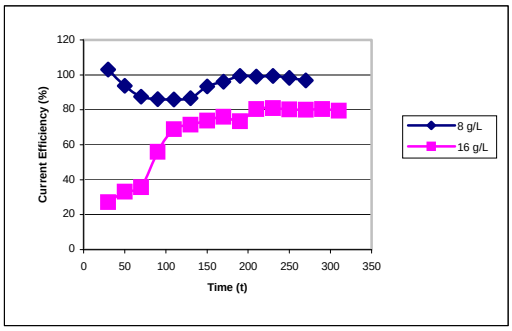

Figure 6. Variation of current efficiency with removal time for the different conc. of the feed solution (Applied voltage: 15 V; pH: 3; flow rate: 2.60 $mL.s^{-1}$)

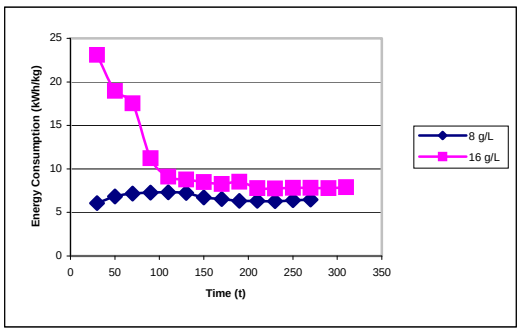

Figure 7. Variation of energy consumption with removal time for the different conc. of the feed solution (Applied voltage: 15 V; pH: 3; flow rate: 2.60 $mL.s^{-1}$)

3.5 Influence of pH

Citric acid is a weak acid and its dissociation depends on pH. Vera et al. (2007) declared that at the initial pH of clarified tropical fruit juices, close to 3, the dissociation of citric acid is higher than that of malic acid and they concluded that the ED performances were not affected by the final pH up to 7.9. We have also studied the feed solution of pH 3 which is close to the original pH value of the diluted solution (8 $g.L^{-1}$). The experiments were also carried out at pH 4 in order to observe the effect of initial pH of the feed solution.

As shown in Fig. 8-9, when the different pH values of feed solution were compared in view of current efficiency and energy consumption, it can be seen that the trends are just opposite. For example, in the case of pH 4, the higher energy consumption corresponds to the lower current efficiency while the lowest energy consumption corresponds to the highest current efficiency in the case of pH 3. Finally, it was concluded that starting the experimental studies with the feed solution pH value of 3 was suitable for the applied experimental conditions.

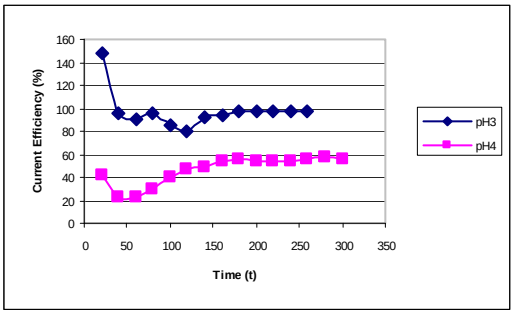

Figure 8. Variation of current efficiency with removal time for different pH values of the feed solution (Applied voltage: 15 V; flow rate: 2.60 mL.s^{-1}; conc. of the feed solution: 8g.L^{-1})

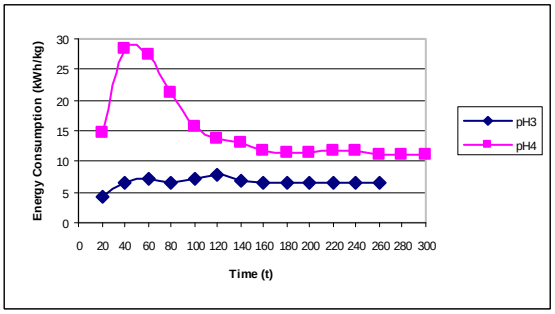

Figure 9. Variation of energy consump. with removal time for different pH values of the feed solution (Applied voltage: 15 V; flow rate: 2.60 mL.s^{-1}; conc. of the feed solution: 8g.L^{-1})

4. Conclusion

- ED with ion Exchange membrane used in this study provides a convenient way to recover the citric acid from dilute solutions .
- The results of this work can also serve as a basis for the laboratory and pilot scale studies on the treatment of whey, juices and wine.

Keywords: *Pichia pastoris*, ROL, mixed substrate co-feeding, sorbitol, fed-batch cultivation, heterologous protein.

Topic: Bioprocess Engineering.

Introduction

The methylotrophic yeast *Pichia pastoris* has become a well-established host system for heterologous protein production (Macauley-Patrick et al., 2005).

There are three types of *P. pastoris* host strains available that vary with regard to their ability to utilize methanol. The wild type or methanol utilization plus phenotype (Mut^+), and those resulting from deletions in the *AOX1* gene, methanol utilisation slow (Mut^S), or both *AOX* genes, methanol utilisation minus (Mut^-). An important advantage of Mut^S strains is that the culture is not as sensitive to residual methanol in the cultivation media relative as Mut^+ strains, and hence the process of scale up can be easier (Stratton et al., 1998). However, the lower maximum specific growth rate of wild type Mut^S strains compared with wild type Mut^+ strains limits the productivity of the process.

To increase cell density and process productivity, as well as to reduce the induction time, a typical approach is the use of a multicarbon substrate in addition to methanol (Files et al., 2001). It has proved to be a straightforward strategy to increase the energy supply to recombinant cells (Zhang et al., 2003). This strategy has been mostly employed for fermentations using Mut^S strains because of their genetically reduced capacity to assimilate methanol, which results in long induction times (above 100 h).

Sreekrishna et al., (1997) successfully implemented the use of sorbitol/methanol mixtures in fed-batch fermentations for matrix metalloproteinases (MMP-2) production. Moreover, Thorpe et al., (1999) compared methanol/glycerol and methanol/sorbitol fed-batch mixed-feed strategies maintaining the residual methanol concentration between 1-2 $g \cdot l^{-1}$. Although cell yields are lower on sorbitol, this is compensated by higher specific product formation rates, which results in comparable recombinant protein levels at lower final cell concentrations. Inan and Meagher (2001) compared different carbon sources in terms of their ability to support growth and expression of an *AOX1-lac Z* fusion in shake flasks studies of a *P. pastoris* Mut^- strain confirming sorbitol as an excellent non-represive carbon source.

The production of the heterologous *Rhizopus oryzae* lipase (ROL) has been shown to have a negative effect on *P. pastoris* growth (Minning et al., 2001). This effect was even more drastic when ROL gene dosage was increased, particularly when using a Mut^S host strain growing on methanol as a sole carbon source in fed-batch cultures (Cos et al., 2005). Thus, sorbitol co-feeding should be an excellent approach to bypass this problem.

Ramon et al., (2007) showed that mixed substrate strategy applied to a Mut^S ROL fed-batch culture at a low residual methanol concentration set-point (0.5 $g \cdot l^{-1}$) allowed to increase the production of heterologous protein in Mut^S phenotype, avoiding the drastic reduction of the specific production rate observed after the start of the induction phase when methanol is used as a sole carbon source. This fact, together with the higher specific growth rate

achieved resulted in a significant increase of the bioprocess volumetric and specific productivities. Recently, Jungo et al., (2007) has published an excellent article about the influence of different mixed feed of methanol and sorbitol working under limited conditions on the recombinant avidin production. However, for our knowledge, there are not studies about the influences of different methanol set-points and specific growth rates on heterologous protein production with this two mixed substrates.

The objective of this work is a systematic study of the influence of methanol set-point and sorbitol feeding rate in fed-batch operation with Mut^S phenotype producing heterologous ROL.

Materials and methods

Strains

P. pastoris KM71 (*arg4 his4 aox1Δ::SARG4 AOX2*, derived Mut^S strains having single copy of the ROL gene and its histidine auxotrophy reverted have been described in Cos et al., (2005).

Fed-batch cultivation set up and operational conditions

The basal salt synthetic medium for fed-batch cultivations contained per litre of distilled water: H_3PO_4 (85%) 26.7 ml, $CaSO_4$ 0.93 g, K_2SO_4 18.2 g, $MgSO_4 \cdot 7H_2O$ 14.9 g, KOH 4.13 g, glycerol 40 g, and 4.35 ml of PTM1 solution. Also 0.1 $ml \cdot l^{-1}$ of antifoam agent (Mazu DF 7960) –a polyoxyalkylene glycol- was added.

Cells were cultured in a 5 litre Braun Biostat B bioreactor (Braun Biotech, Melsungen, Germany). The cultivation conditions were: stirring rate 900 rpm, temperature 30 ºC, pH controlled at 5.5 by adding NH_4OH 30 % (v/v), dissolved oxygen above 30 % with a constant air flow rate of 1.5 $l \cdot min^{-1}$.

The cultivation started with a 40 $g \cdot l^{-1}$ of glycerol batch phase (BP). After that, a pulse of sorbitol and methanol was added to achieve a concentration of 10 $g \cdot l^{-1}$of sorbitol and 5 $g \cdot l^{-1}$of methanol into the bioreactor as a transition phase (TP).

For the induction phase (IP) a feeding medium containing per litre 300 grams of sorbitol and 7.5 ml of trace salts solution was used in a pre-programmed exponential feeding rate strategy at a selected specific growth rate; maximum specific growth rate (0.02 h^{-1}) and a half of maximum specific growth rate (0.01 h^{-1}) .

Methanol addition rate was programmed by a control algorithm developed (Cos et al., 2006) attempting to maintain a 0.5 $g \cdot l^{-1}$ or 2 $g \cdot l^{-1}$ constant methanol concentration adding a solution of pure methanol with 12 $ml \cdot l^{-1}$ of PTM1. Methanol was analyzed on-line by a Methanol detector and sensor unit (Raven Biotech Inc., Vancouver, Canadà). Both carbon sources were also added in the production phase by an automatic microburette MicroBU-2031 from Crison Instruments (Alella, Barcelona, Spain).

Biomass Analysis

Biomass was expressed as dry cell weight (Ramon et al., 2007).

Glycerol, Sorbitol and methanol determination

Off-line glycerol, sorbitol and methanol determination was made as reported elsewhere (Ramon et al., 2007).

Lipolytic activity assay

Lipolytic activity determination was carried out using the Lipase colorimetric assay (LIP kit, reference no. 1821792, from Roche Diagnostics, Mannheim, Germany), as described in Ramon et al., (2004). Extracellular lipolytic activity was measured after removing cells from cultivation samples by centrifugation in a microcentrifuge at 12,000 g.

Results and discussion

In previous Mut^S fed-batch experiments using methanol as sole carbon source it was observed that the highest secretion levels were detected at the lowest methanol set-point tested (0.5 g·l^{-1}). However, the specific production rate profile under those conditions showed a maximum value soon after the start of the induction phase, followed by an abrupt decrease to almost zero values after 20 h of induction. (Cos et al., 2006). Under these conditions, the negative effect of ROL production on cell growth is combined with the reduced methanol assimilation capacity of Mut^S cells. This effect became more striking when attempting to grow the prototrophic Mut^S ROL multi copy strain in fed-batch cultures, as growth on methanol during the fed-batch induction phase did not progress for more than 24 hours.

Preliminary studies of Ramon et al., (2007) showed that mixed substrate (sorbitol-methanol) strategy applied to a Mut^S ROL fed-batch culture at a low residual methanol concentration set-point (0.5 g·l^{-1}) allowed to increase the production of heterologous protein in Mut^S phenotype, avoiding the drastic reduction of the specific production rate observed after the start of the induction phase when methanol is used as a sole carbon source. This fact, together with the higher specific growth rate achieved resulted in a significant increase of the bioprocess volumetric and specific productivities.

Remarkably, sorbitol co-feeding in Mut^S ROL multi copy strain batch cultivations allowed sustained cell growth and lipase productivity, strongly suggesting that cells growing on mixed substrates can –at least partially- overcome the stress caused by ROL overexpression in Mut^S cells. Furthermore, this observation reveals that the (stress) cellular response to heterologous protein overexpression and secretion is interconnected with the energetic state of the cells.

To make a systematic study of the influence of methanol set-point and sorbitol feeding rate in fed-batch operation with Mut^S phenotype, four experiments were made at a constant methanol set-point of 0.5 g·l^{-1} and 2 g·l^{-1} controlling by a predictive control algorithm (Cos et al., 2006) with two different sorbitol feeding rate to assure a constant specific rate of μ_{max} and $\mu_{max}/2$ by means of a pre-programmed exponential feeding rate strategy.

The experiment showed that methanol set-point is the key parameter to optimize production, productivity and specific productivity of the bioprocess. Low influence of specific growth rate on productivity and specific productivity was observed.

For this reason only the fermentations at constant specific growth rate of $\mu_{max}/2$ and methanol set-point of 0.5 g·l^{-1} and 2 g·l^{-1} are presented. The evolution of biomass, lipolytic activity, methanol and sorbitol for a methanol set-point of 0.5 g·l^{-1} are presented in figure 1, and the same parameters at methanol set-point of 2 g·l^{-1}, are presented in figure 2.

An accurate pre-programmed exponential feeding rate strategy for sorbitol concentration (open-loop control) was reached; specific growth rate was maintained practically constant at set-point value of 0.01 h^{-1} without sorbitol accumulation. Thus, sorbitol was limited substrate.

On the other hand, methanol closed-loop control strategy using the predictive control algorithm previously developed was also effective. The two methanol set-points were maintained with minimal deviations along the fermentation.

The efficient of control strategies for both substrates permits an accurate study of the effect of both parameters on the productivities of the ROL production bioprocess, and it reveals the importance of PAT (process analytical technology) to obtain reproducible bioprocesses.

Biomass levels were very similar in both bioprocesses. It reveals that practically all biomass production is related with sorbitol consumption and the effect of different methanol set-points on biomass production is negligible.

Also the influence of ammonium addition in the induction phase was tested. Basal salt medium has only ammonium to reach a biomass concentration around 30-40 g·l^{-1}.The lack of ammonium has a negative effect on microorganism growth and protein production, also it

starts the proteolytic processes. One pulse of ammonium during the induction phase showed, in some fermentations, a negative influence on *Pichia* growth and protein production as it has been also revealed in a drastic depletion of CO_2 production rate (data not shown). Although growth and production was recovered after a lag phase of some hours, obviously this strategy is not applicable. The best strategy to avoid these problems was to feed ammonium jointly with sorbitol in their stoichiometric relation during the induction phase.

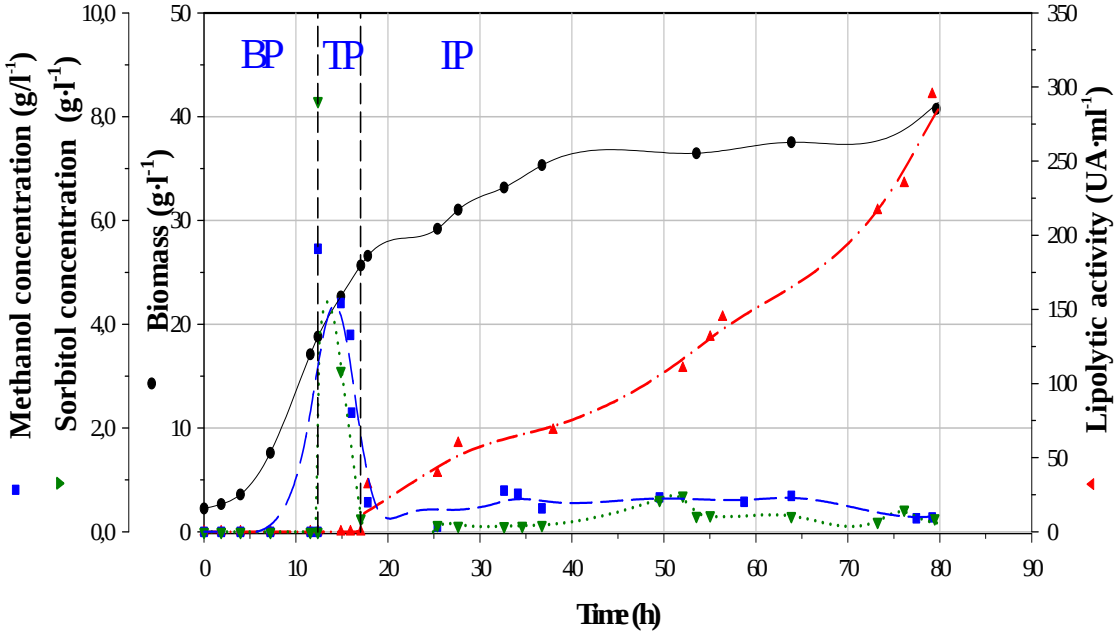

Figure 1.- Time evolution of biomass, methanol, sorbitol and lipolytic activity for a methanol set-point of 0.5 g·l^{-1} at a specific growth rate of 0.01 h^{-1} (μ_{max}/2).

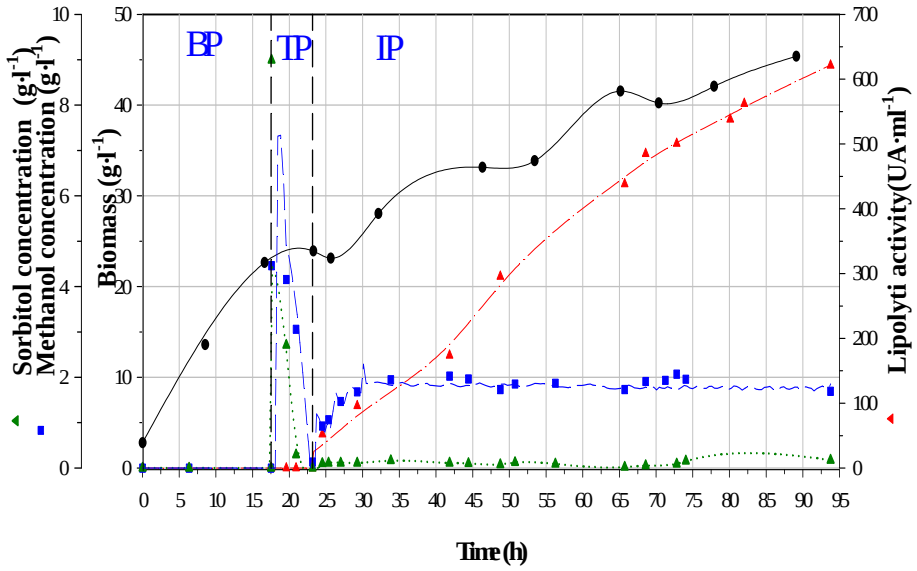

Figure 2.- Time evolution of biomass, methanol, sorbitol and lipolytic activity for a methanol set-point of 2 g·l^{-1} at a specific growth rate of 0.01 h^{-1} (μ_{max}/2).

A different behaviour was observed when lipolytic activity was compared. At methanol set-point of 2 $g \cdot l^{-1}$, lipolytic activity was 2.4 fold higher than methanol set-point of 0.5 $g \cdot l^{-1}$. It shows the importance of methanol set-point on heterologous protein production in *Pichia pastoris* and the pressing need to get an accurate control of substrate inductor (methanol).

The evolution of specific production rates of both bioprocesses were also quite different (Figure 3). Heterologous protein production starts at the beginning of the induction phase. Both methanol set-points reached a maximum of specific production rate during the first ten hours of the induction phase, and did not fall downs abruptly as observed when cells was grown on methanol as sole carbon source at the same point of 0.5 $g \cdot l^{-1}$ (Cos et al., 2006). The maximum specific production rate reached at methanol set-point of 2 $g \cdot l^{-1}$ was 2.8 fold higher than methanol set-point of 0.5 $g \cdot l^{-1}$.

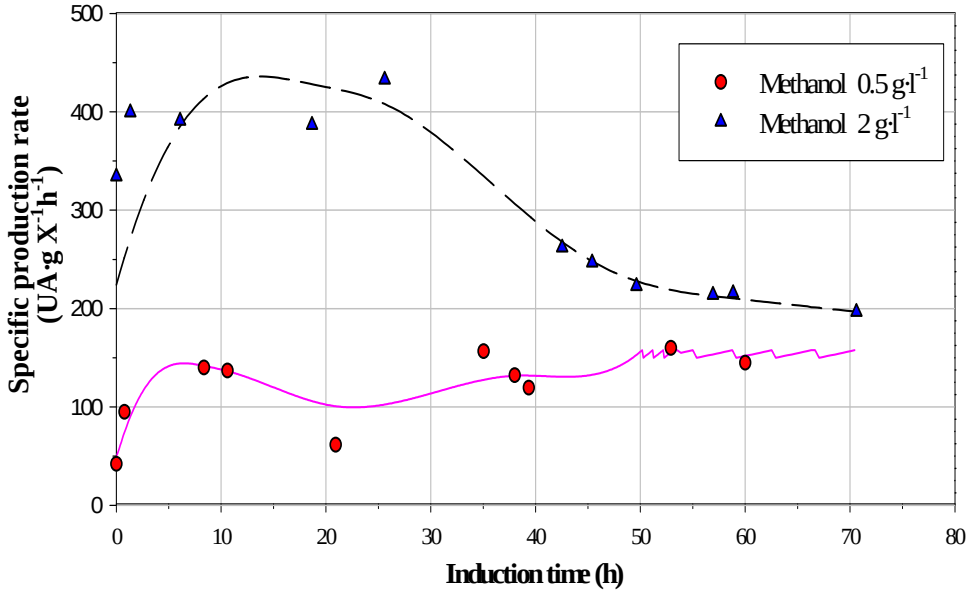

Figure 3.- Time evolution of specific production rates at methanol set-points of 0.5 and 2 $g \cdot l^{-1}$ at a specific growth rate of 0.01 h^{-1} ($\mu_{max}/2$).

At a low methanol set-point, specific production rate was maintained practically constant along the fermentation (around 150 $UA \cdot gx \cdot h^{-1}$). However, at high methanol set-point, the maximum (around 425 $UA \cdot gx \cdot h^{-1}$) was maintained only during 25 hours decreasing previous to stabilize at 200 $UA \cdot gX \cdot h^{-1}$, a value little bit higher than observed at low methanol set-point.

It has been shown that methanol set-point is the key fermentation parameter in the modulation of heterologous protein production in *Pichia pastoris*. On the other hand, the modulation of transcriptional level and the use of a co-substrate such as sorbitol minimizes the negative impact of high-level protein expression on cell physiology and growth rate reduction.

Abstract

P. pastoris processes for heterolougous protein expression are typically run in three phases: a batch phase, an exponential feeding fed-batch phase and a long oxygen transfer limitation (OTL) phase. The final protein titer is often limited by the oxygen availability in the OTL phase. In this paper, a direct adaptive controller is designed for the OTL phase. The controller was validated in pilot *P. pastoris* cultivations expressing a single chain antibody fragment (ScFv). This work shows that the proposed controller can regulate the dissolved oxygen tension (DOT) at very low levels (5 %) with high stability by manipulating the glycerol feeding rate, thereby enhancing the oxygen transfer at high cell density, which finally leads to a higher antibody titre.

1 Introduction

Pichia pastoris is currently viewed as a very promising host for heterologous protein expression (Cereghino and Cregg, 2000) since it can be easily manipulated at molecular genetic level, it has the ability to express high levels of proteins, either intra or extracellularly and it has the capability to perform eukaryotic post-translational modifications such as glycosylation, disulfide bond formation and proteolytic processing (Cereghino and Cregg, 2000; Cereghino et al., 2002).

In recent studies, *P. pastoris* has been genetically engineered to secret human glycoproteins, such as rEPO, with homogeneous fully complex terminally sialylated N-glycans (Hamilton et al., 2003, 2006; Choi et al., 2003; Bobrowicz et al., 2004). These studies open new perspectives for the production of therapeutic proteins in yeast cell cultures with advantages such as reducing both fermentation and development (from gene to protein) times, lower operating costs, chemically defined media, higher protein titers and no viral contamination.

P. pastoris is normally cultivated in fed-batch mode in order to limit the amount of substrate in the reactor. It can tolerate wide pH variations but it doesn't seem to increase its cell productivity with pH changes, although achieving different protease activities (Shi et al., 2003).

This yeast is able to grow at very high cell densities with massive oxygen uptake requirements, being the oxygen transfer capacity, a critical limitation factor. Charoenrat et al. (2006) concluded that high cell productivity could be improved by increasing oxygen transfer rate.

*Corresponding author. Tel: +351 21 2948303 E-mail: rui.oliveira@dq.fct.unl.pt

Once the maximum oxygen transfer rate is reached, regulation of DOT at very low values by manipulating the carbon source feeding has been proposed by several authors. Oliveira et al. (2005) developed two indirect adaptive control algorithms, based on dissolved oxygen (for both algorithms) and oxygen transfer rate (for one of the algorithms) measurements. It was shown that off-gas measurements did not improve the controller performance since responses by estimator and controller were being caused by the measurement delays.

In this paper, a direct adaptive controller is derived and tested in *P. pastoris* cultivations. The production is highly sensitive to the specific methanol feeding in the methylotrophic strains. A controller that can maintain constant specific feedings on the basis of DO control would be of extremely high value.

2 Process control feeding strategy

The control of *P. pastoris* cultivation is based on carbon source limitation, i.e through glycerol feeding. The process starts with a glycerol batch (GB) phase, where the cultivation is carried out in batch mode for 9 hours with initial glycerol concentration of approximately 40 g/l. Then follows the glycerol fed-batch Phase (GFB) according to an exponential profile,

$$F = F_0 e^{\mu t} \tag{1}$$

with F the glycerol feeding rate in g/h, F_0 the initial feeding rate (10.35 g/h) and μ the desired specific growth rate, set to 0.16 h^{-1} in this work.

In GB and GFB phases, dissolved oxygen concentration is controlled in cascade mode, first by overhead pressure between 80 and 500 mbarg to regulate dissolved oxygen level to 95 % of saturation and, as second control loop, agitation rate between 320 and 1000 rpm to regulate the dissolved oxygen level to 50 % of saturation. At the end of the GFB, the stirrer speed reaches the maximum value of 1000 rpm and DO starts to drop thereby signaling the beginning of oxygen transfer limitation phase. In this latter phase an adaptive DO-stat feeding controller was implemented.

3 Adaptive DO-stat glycerol feeding controller

3.1 System description

To describe the dissolved oxygen dynamics in the liquid phase, the following material balance equation holds when glycerol accumulation in the liquid phase is negligible:

$$\frac{\mathrm{d}C_O}{\mathrm{d}t} = -\frac{F}{V} S_0 Y_{O/S} + k_L a \left(C_O^* - C_O\right) \tag{2}$$

with C_O the dissolved oxygen concentration, F the glycerol solution feed rate, V the broth volume, S_0 the glycerol concentration in the feed solution, $Y_{O/S}$ the observed oxygen/glycerol yield, that may change in time, $k_L a$ the oxygen mass transfer coefficient, C_O^* is the saturation dissolved oxygen concentration at working conditions. Equation (2) can be rearranged in the following equations:

$$\frac{\mathrm{d}x}{\mathrm{d}t} = -a_p x + k_p F \tag{3a}$$

with

$$x = 100 - DOT \tag{3b}$$

$$k_p = \frac{S_0 Y_{O/S} 100}{V C_O^*} \tag{3c}$$

$$a_p = k_L a \tag{3d}$$

It should be noted that due to the time-varying nature of $Y_{O/S}$, k_La, V and C_O^*, equations (3a)-(3d) form a linear time-varying dynamical system. Nevertheless, the dynamics of k_p and a_p are expected to be much slower than x. Thus this system can be classified as a linear quasi time-invariant system. (Narendra and Annaswamy, 1989).

3.2 Controller design

The goal is to derive a control law for x by manipulating the glycerol feed rate and by considering k_p and a_p as piecewise time-varying unknown parameters. A model reference design was adopted in which the process dynamics is forced to follow a linear reference model:

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \frac{x^* - x}{\tau_c} \tag{4}$$

with x^* the desired set-point for x and τ_c a first order time constant. Combining (3a) and (4), results in the following controller equation:

$$F = \theta\left(t\right) x + K\left(t\right) x^* \tag{5a}$$

with

$$\theta\left(t\right) = \frac{a_p\left(t\right) - \dfrac{1}{\tau_c}}{k_p\left(t\right)} \tag{5b}$$

$$K\left(t\right) = \frac{1}{\tau_c k_p\left(t\right)} \tag{5c}$$

If a_p and k_p are unknown and time-varying then stability can only be garanteed through on-line adaptation of θ^* and K^*. The following adaptation laws were adopted:

$$F = \hat{\theta}\left(t\right) x + \hat{K}\left(t\right) x^* \tag{6a}$$

$$\frac{\mathrm{d}\hat{x}}{\mathrm{d}t} = \frac{x^* - \hat{x}}{\tau_c} \tag{6b}$$

$$\frac{\mathrm{d}\hat{\theta}}{\mathrm{d}t} = \frac{\mathrm{d}\left(\hat{\theta} - \theta\right)}{\mathrm{d}t} = -\gamma x e \tag{6c}$$

$$\frac{\mathrm{d}\hat{K}}{\mathrm{d}t} = \frac{\mathrm{d}\left(\hat{K} - K\right)}{\mathrm{d}t} = -\gamma x^* e \tag{6d}$$

with

$$e = x - x^* \tag{6e}$$

$\hat{\theta}$ and $\hat{K}$ are estimates of θ and K respectively, γ is a tuning parameter. It may be shown that this system is uniformly stable in the Lyapunov sense.

4 Results and discussion

4.1 Typical process dynamics

A constitutive *P. pastoris* strain expressing ScFv was cultivated in a pilot bioreactor. Figure 1 illustrate the process dynamics.

From Figure 1(a), it can be seen that the control cascade worked as expected. In the first control step, pressure was kept constant at 100 mbarg – at the end of this phase, cell density was still low (∼80 gWCW/l); when DO dropped to 50 %, the stirrer speed increased up to 1000 rpm (achieving high cell density of around 600 gWCW/l), remaining at this value until the end of the fermentation. For the last phase, the adaptive DO-control was initiated, regulating DO steadily at 5 % saturation.

4.2 Factors affecting productivity

In the present analysis, four factors were hypothesized to affect productivity, namely pH, DO concentration, medium composition and starting biomass concentration, which are shown in Table 1.

In what concerns pH, there seems to be an increase in productivity when pH is decreased, which comes accordingly with a previous study (Jahic et al., 2003), due to inhibition of proteolysis. As for DO concentration, when the DO set point is decreased (during OTL), an increase in productivity is usually observed. When DOT is lowered, the driving force of oxygen transfer rate (OTR) is increased and consequently, the OTR is also increased. With an increased OTR, there will be a higher supply of oxygen to cells which is critical for high productivity. Defined medium shows an inferior productivity when comparing to complex medium, most likely because important constituents may be missing in the medium. For the influence of initial biomass concentration on productivity no visible correlation seems to apply.

4.3 Effect of controller on productivity

As stated previously, having a controller that can maintain a constant and low DOT is a valuable tool in *P. pastoris* cultivation. In Figure 1(a) it is shown that the adaptive controller was robust and stable in regulation DOT to 5 %. Another benefit of this controller is that it can maintain its specific feeding close to the theoretical maximum, which would be if for DOT = 0 % (Figure 2). Therefore, with this

controller it is expected to increase productivity when comparing with previous fermentations, without such control.

5 Conclusions

In this work, an adaptive controller was derived that proved to regulate the DOT at a very low levels ($\sim$5 %) in a *P. pastoris* cultivation process with high accuracy. With the presented controller, it was possible to limit the carbon source availability such that the oxygen mass transfer is maximised. As a result,the process productivity and final antibody fragment titre could be increased.

Keywords: *Yarrowia lipolytica*, biodegradation, crude oil.
Topic: Integration of life sciences & engineering.

Abstract

In the present work, the degrading potential of an aerobic alkane assimilating yeast, *Yarrowia lipolytica* IMUFRJ 50682, isolated from tropical estuarine water, is evaluated. Even showing a greater potential to degrade aliphatic hydrocarbons*, Y. lipolytica* was evaluated in terms of crude oil degradation. An experimental design was performed varying the initial cell concentration (0.1 - 1.0 mg/ml), initial petroleum concentration (0.1 - 1.0% (v/v)), agitation speed (70 - 160 rpm) and glucose concentration (0 - 1.0 mg/ml). The results show the microorganism great potential to degrade crude oil. *Y. lipolytica* was capable assimilating hydrocarbons up to 20 carbons.

Introduction

Oil spills pose a great hazard for terrestrial and marine ecosystems. The total annual influx of oil into the sea is estimated to be approximately 5.2 million tones, and in productive areas it is almost unavoidable (Leahy and Colwell, 1990). Therefore, a search for new technologies to clean up oil-polluted environments is urgent.

Many microorganisms have the ability to utilize hydrocarbons as sole carbon sources of energy and carbon. Biodegradation is a microbial process whereby the petroleum is used as an organic carbon source, resulting in the breakdown of petroleum components to compounds of lower molecular weight or the transformation of petroleum components to more polar compounds of a carbon number equal to the parent compound. Naturally occurring microorganisms in a contaminated site are already biodegrading the pollutant. Addition of microorganisms in these sites may enhance contaminant removal (Aldrett *et al.*, 1997). The growth of microorganisms on hydrocarbons is often accompanied by the emulsification of the insoluble carbon source in the aqueous phase (Reddy *et al.*, 1982). In some cases, this has been due to the production of extracellular emulsifying agents during hydrocarbons breakdown (Ilori *et al.*, 2005).

Yarrowia lipolytica is an unique strictly aerobic yeast with the ability to degrade very efficiently hydrophobic substrates such as n-alkanes, fatty acids, fats and oils for which it has specific metabolic pathways (Fickers *et al.*, 2005). Kim *et al.* (1999) isolated yeast from an industrialized oil polluted area and verified it was capable to removed 94% of aliphatic hydrocarbons. Analyzing the genetic material of this microorganism concluded it was *Yarrowia lipolytica*. Analyzing 6 different yeast species for crude oil degradation, Zinjarde and Pant (2002) concluded that *Yarrowia lipolytica* was the best degrader utilizing 78% of the aliphatic fraction of Bombay High crude oil.

In the present work, yeast isolated from an estuarine in Guanabara Bay in Rio de Janeiro, Brazil, *Y. lipolytica* IMUFRJ 50682, was evaluated for its crude oil degradation ability. This strain has shown unique surface characteristics such as a high hydrophobicity (Amaral *et al.*, 2006a), which facilitates the contact with the oil phase, and also production of a bioemulsifier (Amaral *et al*., 2006b).

Materials and methods

Materials

Peptone and yeast extract were obtained from Oxoid (Hampshire, UK) and glucose from Reagen (Rio de Janeiro, Brazil).

The crude Oil was provided by *Petróleo Brasileiro* S.A. (PETROBRAS, Brazil), Marlin petroleum: 18,93 ºAPI; asphaltenes = 3,1%; resins/asphaltenes = 8.1; saturated hydrocarbons/aromatic hydrocarbons = 1.6; 2.66% of N, S and O.

Strain, Media and Culture Conditions

A wild type strain of *Yarrowia lipolytica* (IMUFRJ 50682) was selected from an estuarine in the vicinity of Rio de Janeiro, Brazil (Hagler and Mendonça-Hagler, 1981) and maintained at 4ºC on YPD-agar medium. Cells from a preculture, cultivated for 48 h in YPD medium (w/v: Yeast Extract, 1%; Peptone (from casein), 2%; Dextrose, 2%) at 160 rpm, in stationary phase of growth, were centrifuged and used to inoculate 250 mL shake flasks containing 100 mL of mineral medium (g/L: NaCl, 3.5; K_2HPO_4, 0.7; KNO_3, 2.1; $NH_4H_2PO_4$, 0.1; $(NH_4)_2SO_4$, 0.1; $MgSO_4.7H_2O$, 0.02) and the crude oil. To study the influence of glucose, some experiments were realized with 1% (w/v) of glucose in the mineral medium.

Crude oil degradation studies

Before inoculating the cells in the mineral medium, the crude oil was added to the medium. The control experiment was performed without the crude oil. The control experiment was performed without the crude oil. Cells were cultivated at 28ºC in a rotary shaker at 70, 155 and 160 rpm.

Analytical Methods (in aqueous phase)

Cell Growth: Cell growth was followed by optical density measurements at 570 nm converted to mg/ml using a factor previously established. When mentioned in the text, cell growth was determined by plate counting on YPD Agar of susceptive diluted cell suspension, after incubation of 48 h at 28ºC.

Glucose: Extracellular glucose concentration was determined by glucose oxidase method (Enzymatic Colorimetric Glucose Assay Kit, HUMAN GmbH - Germany).

Determination of crude oil degradation

To analyze crude oil degradation, an extraction of the oil phase was performed with chloroform (1:1) in flasks from the beginning (control) and at the end of the crude oil degradation studies. After that, the chloroform solution with extracted crude oil was diluted (when needed) and was analyzed in a spectrophotometer (DR4000UV (HACH)) by a wavelength scan. A solution of crude oil in chloroform in concentration of 9.55 g/l was prepared and some dilutions were performed. For each dilution a wavelength scan was performed in order to show a relation between petroleum concentration and absorbance.

Experimental design and optimization

A 2^2 full-factorial design with two levels leading to a set of 16 experiments was performed more three central points totaling 19 experiments. The range and the levels of the variables here in investigated are given in Table 1. The maximum biomass concentration ($\Delta X_{máx}$) and maximum specific growth rate ($\mu_{máx}$) were taken as the dependent variables or response of the designed experiments. 'Statistica' (version 6.0) software was used for regression and graphical analyses of the obtained data. The statistical significance of the regression coefficients was determined by Student's t-test.

Table 1. The experimental range and levels of the independent variables

Factor	Symbol	Range and levels		
		-1	0	1
Agitation speed (rpm)	Agitation	70	115	160
Initial cell concentration (mg/ml)	[Cells]	0.1	0.55	1.0

Initial crude oil concentration (%, v/v)	[Crude Oil]	0.1	0.55	1.0
Initial glucose concentration (mg/ml)	[Glucose]	0	0.5	1.0

Gas Chromatographic analysis of Crude Oil

Gas chromatographic analyses (GC-MS) were carried out on a Hewlett-Packard Model 6890 Plus equipped with automatic sampler Agilent 7673. Separations were achieved using a capillary column coated with DB-5 (J&W Scientific, 25 m x 0.25 mm i.d., 0.25 μm film thickness) and flame ionization detection (FID). The column temperature for analyses was programmed from 60 ºC to 320 ºC at a rate of 6 ºC min^{-1} and held at 320 ºC for 20 min. The injector was heated at 290 ºC and the flame ionization detector at 340ºC. Helium was used as carrier gas. The samples were injected in splitless mode, injection volume of 1 μL.

Results and Discussion

Crude oil degradation

In order to verify *Y. lipolytica*'s degradation potential of crude oil, the variables studied were: initial cell concentration (0.1, 0.5 and 1.0 mg/ml), initial petroleum concentration (0.1, 0.55 and 1.0% (v/v)), system agitation speed (70, 115 and 160 rpm) and presence of glucose (0, 0.5 and 1.0 g/L), in a full factorial design with three replicates in the central point.

A reduction in biomass concentration was observed in the beginning of the experiments. Figure 1 shows microscopic observations depicting cell adhesion to the crude oil. This phenomena seems to occur because of the amphiphilic surface of this *Y. lipolytica* strain (Amaral et al., 2006a). Therefore cell concentration measurements in aqueous phase were underestimated.

Figure 1. Optic Microscopy of *Yarrowia lipolytica* (1000X)

The first step in the process of seeking optimum conditions is to identify the input variables that have the greatest influence on the experimental response. Figure 2 shows all the variables and their effect in ΔXmáx (Fig. 2-A) and μmáx (Fig. 2-B). The variables with P-values inferior to 0.05 are not statistically significant at the 95% confidence level. It is possible to observe that the individual variable that most influences ΔXmáx and μmáx is the initial cell concentration, followed by the system agitation speed. The initial petroleum and glucose concentration are the variables that have minor influence in cell growth (ΔXmáx and μmáx).

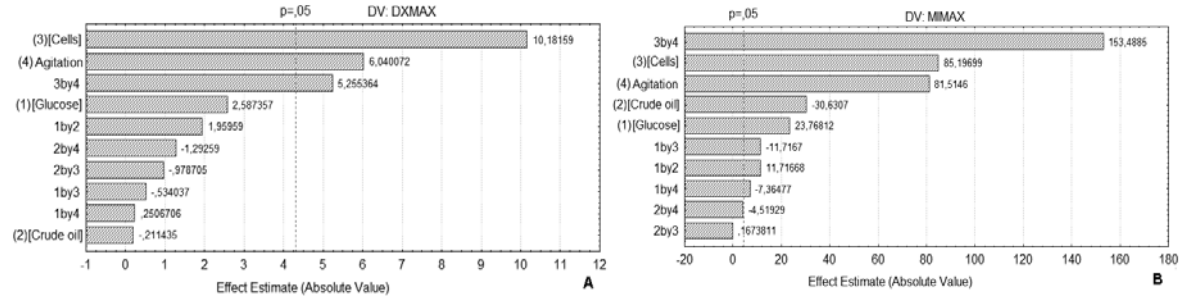

Figure 2. Pareto Chart – Effect of the dependent variables in maximum biomass produced per volume (ΔXmáx) (A) and the maximum specific growth rate (μmáx) (B).

The cells grow faster when the system agitation speed is higher in the presence of higher initial cell concentration. Jobson et al. (1972) worked with several cultures isolated from contaminated soil and the growth rate was not affected by raising aeration. However, *Y. lipolytica* is a strictly aerobic yeast and its growth and metabolites production are influenced by oxygen availability (Amaral et al., 2006b, Alonso et al., 2005). Therefore, higher agitation speed promoted a higher system oxygenation and, consequently, a higher biomass yield.

In the presence of high petroleum concentration, glucose is needed to obtain higher cell production. Kim et al. (1999) also detected increasing *Y. lipolytica*'s cell number as oil concentration raised. Glucose is degraded in the beginning of the experiment as Figure 3 depicts. Being an easily degradable carbon source, glucose is readily consumed producing higher cell concentration that will degrade petroleum. When initial the cell concentration is higher the presence of glucose becomes unnecessary, which indicates that the crude oil compounds assimilation is not associated to cell growth, but related only to cell concentration. However, it is possible to notice that the microorganism grows slightly after glucose starvation, indicating that part of the crude oil assimilation may be designated to cell growth (Fig. 3).

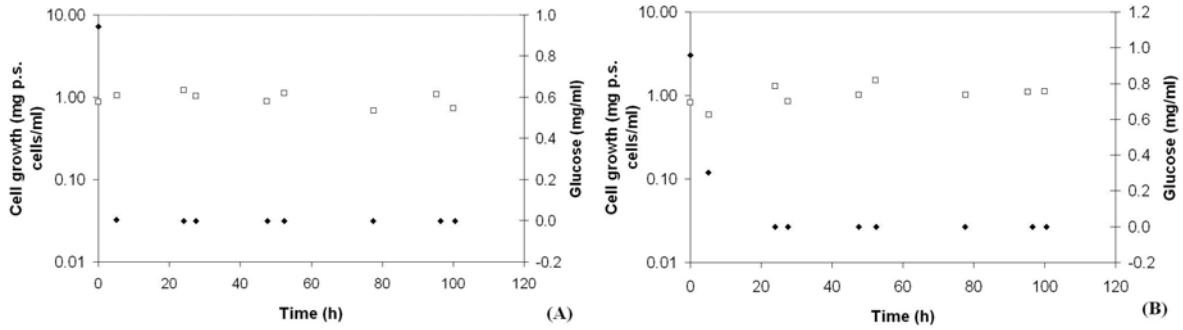

Figure 3. Cell growth profiles (□) and glucose concentration (♦) during crude oil biodegradation. Conditions: 160 rpm agitation speed, with 1.0 mg/ml of glucose, and 1.0 mg/ml initial cell concentration. Initial Crude Oil concentration: (A) 0.1% (v/v); (B) 1.0% (v/v).

Through those results some of the significant conditions to crude oil degradation were chosen: 160 rpm agitation speed and 1.0 mg/ml initial cell concentration. Subsequent experiments with these conditions were performed with cell growth analysis through Colony forming units (CFU), and extraction of oil phase to analyze crude oil degradation. Table 2 shows the results obtained for those experiments. Such results demonstrate that crude oil is used as carbon source for cell growth (experiments without glucose). On the other hand, the presence of this raw material seems to have an inhibitory effect on cell growth when glucose is present, since the number of cells (UFC/ml) obtained in the presence of glucose and petroleum was inferior to that with glucose only. This fact indicates that the cells may need a significant adaptation period to alternate between the consumption of an easily degraded carbon source (glucose) to the crude oil utilization.

Table 2. Colony-Forming Units (UFC) from initial (0 h) and end (120 h) of experiments of crude oil degradation in flasks agitated at 160 rpm. Initial cell concentration: 1.0 mg/ml.

Conditions		UFC/ml	
		Initial	Final
Glucose (mg/ml)	Petroleum (%, v/v)	(x 10-12)	(x 10-15)
0	0.1		1.32
1.0	0.1		0.57
0	1.0	2.32	8.50
1.0	1.0		0.95
1.0	0		1.48

The scanning of the crude oil at UV demonstrated that Marlin petroleum absorbed mostly at three wavelengths: 208, 266 and 388 nm (data not shown). The elevated absorption at 208 nm is due the presence of olefins. Aromatics compounds absorb at 255-275 nm being responsible for the absorption at 266 nm. Paraffins absorbed near VIS being probably responsible for the peak at 388 nm (Silverstein *et al.*, 1991).

Table 3 shows these observations, presenting the crude oil removal for selected wavelengths, which is calculated by Eq. (2):

$$\text{Crude oil removal} = \frac{\text{Abs}_{0h} - \text{Abs}_{120h}}{\text{Abs}_{0h}} * 100 \quad (2)$$

where Abs_i is the absorbance of the sample at the wavelength chosen at i hour of the experiment.

Table 3. Crude oil removal from initial (0 h) and end (120 h) of experiments of crude oil degradation in flasks agitated at 160 rpm. Initial cell concentration: 1.0 mg/ml.

Conditions		Removal (%)		
Glucose (mg/ml)	Crude oil (%, v/v)	208 nm	266 nm	388 nm
0	0.1	5.6	8.2	45.4
1.0	0.1	5.1	7.5	38.0
0	1.0	54.5	59.7	89.0
1.0	1.0	36.8	29.7	80.4

It is possible to notice that crude oil removal by biodegradation is higher for compounds that absorb light in wavelength near 388 nm. Kim *et al*. (1999) has shown 94% degradation rate of saturated aliphatic components in crude oil by *Y. lipolytica*. In the presence of higher crude oil concentration and absence of glucose it is possible to remove more than 50% of crude oil for all selected wavelengths (Table 3).

Gas Chromatographic analysis of Crude Oil

Figure 4 shows the chromatography of the remaining crude oil extracted in the end (Fig. 4-B) of *Y. lipolytica*'s biodegradation tests and in the beginning (Fig. 4-A).

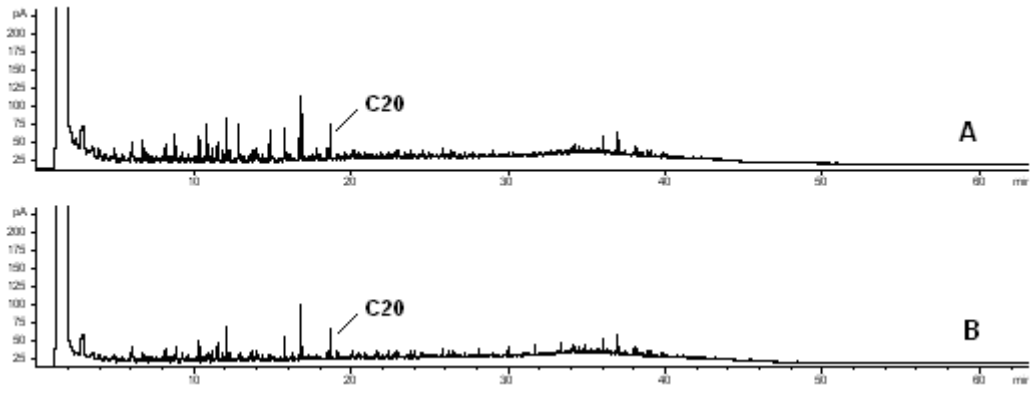

Figure 4. Chromatography of remaining crude oil in the end (B) of of *Y. lipolytica*'s biodegradation tests and in the beginning (A).

Comparing Fig. 4-A with Fig. 4-B it is possible verified that *Y. lipolytica* is capable to assimilate hydrocarbons up to 20 carbons. Some peaks, that are presented before C20 at the chromatography of crude oil in the beginning (Fig. 4-A), do not appear at chromatography of crude oil in the in the end (Fig. 4-B). Also, other peaks before C20 are minors at Fig 4-B indicating that these compounds are less concentrated after biodegradation.

Conclusions

The results here in obtained indicate that *Y. lipolytica* IMUFRJ 50682 has crude oil biodegrading potential, being capable to assimilate hydrocarbons up to 20 carbons. The system agitation that most favored cell growth was 160 rpm due to the aeration rate raise. In flasks containing higher crude oil concentration the observed biodegradation was higher, showing the potential to use this microorganism in crude oil contaminated sites.

The presence of glucose was not positive for the cell growth or crude oil biodegradation, which is an important result for its employment in contaminated sites that may not usually have glucose presence.

Keywords: hyperbaric bioreactor, pressure, cell concentration, *Yarrowia lipolytica*, oxidative stress
Topic: Suitable conference topic — Integration of life sciences & engineering.

Abstract

Increase air pressure for aeration of microbial cell cultures can prevent oxygen limitation but cause oxidative stress and consequently affect cell physiology. A pressurized bioreactor was used for *Y. lipolytica* batch cultivation under increased air pressure up to 6 bar and no inhibition of cell growth was observed. Moreover, an increase of 6-fold led to a 3.4-fold increase in specific growth rate under atmospheric pressure. The antioxidant enzyme superoxide dismutase was induced by the air pressure raise, which indicates that the defensive mechanisms of the cells were effective and cells could cope with increased pressure. The extracellular lipase activity increased from 22.3 to 43.7 U/l using a 5-bar air pressure instead of air at 1 bar pressure.

1 Introduction

Y. lipolytica is a non-conventional yeast, non-toxic, that can grow to very high densities. It has a haploid genome and sexual life cycle, and therefore is amenable to both classical and molecular analysis (Juretzek et al., 2001; Barth and Gaillardin, 1996). It is also advantegeous in studies of the biodegradative pathways for a variety of hydrophobic compounds including alkanes, oils, and fatty acids and thus for its capacity to produce lipid-degrading enzymes, such as lipases.

The amount of oxygen available to *Y. lipolytica* seems to be an important parameter since that strain is strictly aerobic. Many efforts have been made to overcome the oxygen limitation in the culture medium and previous work demonstrated that hyperbaric air could be successfully applied to yeast cultivation, as a way of improving the oxygen transfer rate to aerobic cultures (Lopes et al., 2008; Aguedo et al., 2005; Belo et al., 2003).

In industrial bioreactors, levels and gradients of total and partial pressures are considerably higher than on the laboratory scale. Thus, cells in bioreactors are often exposed to O_2 partial pressures higher than 210 mbar (corresponding to air at 1 bar). In many cases, increased O_2 partial pressure (higher than approx. 1 bar) is toxic to aerobic cultures and inhibits microbial growth and product formation (Onken and Liefke, 1989). During the reduction of molecular oxygen to water through acceptance of four electrons, active oxygen species such as superoxide anion radical ($O_2\cdot^-$), hydrogen peroxide (H_2O_2), and hydroxyl radical ($HO\cdot$) are generated. These active oxygen species may give rise to damage of enzymes, nucleic acids, or lipids (Izawa et al., 1995). To counter oxidative stress, cells constitutively express enzymes that detoxify the reactive oxygen species and repair the damage caused by them. In addition, yeast cells have adaptive responses to elevated levels of oxidative stress, indicating that these cells sense increased levels of reactive oxygen species and transduce the signal into increased expression of defence activities (Storz and Imlay, 1999). Antioxidant enzymes, such as catalase and superoxide dismutase (SOD), constitute the primary

* Corresponding author. Tel + 351-253604413. E-mail:ibelo@deb.uminho.pt

defences of the cells because they are responsible to transform these reactive oxygen species into nonreactive ones (Moradas-Ferreira et al., 1996).

High pressure is typically viewed as a denaturing factor (Dong et al., 2007), however there is a little report about the effects of slight increased air pressure on the growth and metabolism of microbe cells. The aim of this work is to investigate whether increasing air pressures may lead to increasing biomass yields of *Yarrowia lipolytica* W29, without giving rise to oxidative stress. This paper also reports an investigation into the influence of a pre-adaptation phase of cells to hyperbaric conditions on the lipase production by *Y. lipolytica* cells.

2 Materials and Methods

Yarrowia lipolytica W29 (ATCC 20460) was grown in YPD medium. The medium for lipase production was YNB/olive oil as described in Lopes et al. (2008).

Yeast cells were pregrown in 250 ml Erlenmeyer flasks filled with 100 ml of the YPD medium at 140 rpm, 27 ºC of temperature and for 24 h. Batch cultivations were carried out using a 600 ml stainless steel stirred tank bioreactor (Parr 4563, Parr Instruments, USA), with 400 ml of YPD media, at 27 ºC and 400 rpm in order to asses the effect of pressure in cellular growth and on antioxidant enzymes induction. Compressed air was continuously sparged into the culture at a flow rate of 1 vvm. The values of air pressure studied were 1 bar to 6 bar. An experiment in an Erlenmeyer flask (500 ml) with 200 ml of YPD medium, under atmospheric pressure (1 bar) and an agitation rate of 140 rpm was used as a control. With the aim of investigate the influence of a pre-adaptation phase of cells to hyperbaric conditions on the lipase production by *Y. lipolytica* cells, experiments were conducted in the pressurized bioreactor in which the lipase production phase (YNB/olive oil medium, 400 rpm, at 27 ºC for 48 h, Lopes et al. 2008) was preceded by a 24 h growth in YPD medium at 1 bar or 5 bar of total air pressure.

Culture samples were collected for analysis of cell concentration (optical density at 600 nm and cell number and converted to g cell dry/l), total soluble protein, glucose consumption and enzymatic assays. Total soluble protein was obtained by Bradford's method. Glucose was determined using the 3,5-dinitrosalycilic acid (DNS) method. Extracellular lipase was measured in the samples supernatant using *p*-nitrophenyl-butirate (pNPB) in sodium acetate buffer 50 mM at pH 5.6 as a substrate, at 37 ºC for 15 min. One unit of activity was defined as the amount of enzyme that produces 1 µmol of *p*-nitrophenol per minute under assay conditions. Protease in cell-free samples was quantified as described in Lopes et al. (2008). The antioxidant enzymes were measured after dialysis of the cell extracts, which were obtained as described in Pinheiro et al. (2000). Catalase was assayed using the method described by Beers and Sizer (1952) and superoxide dismutase (SOD) was quantified by the method of Marklund and Marklund (1974).

3 Results and Discussion

Air effects on cell growth

Typical batch growth curves and glucose consumption profiles for the experiments under increased air pressure and atmospheric pressure are shown in Figure 1.The application of 6 bar stimulated cell growth compared to the atmospheric conditions.

Pressure increase had a clear positive effect on this yeast metabolism, since the biomass production increased and reached its maximal value for an air pressure of 6 bar. An increase of the cell dry weight at 6 bar of 3.5- and 5-fold was obtained compared with the experiments under atmospheric pressure in the control and in the bioreactor, respectively.

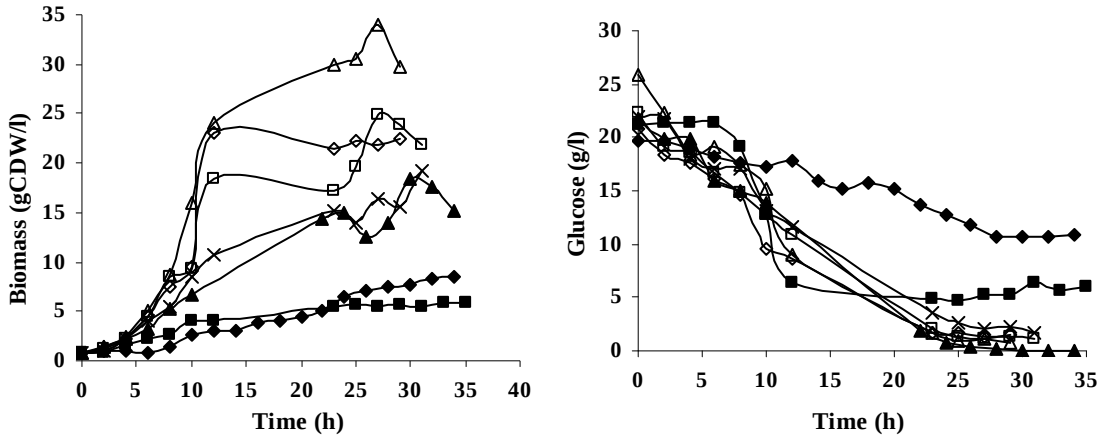

Fig. 1 Batch growth and glucose consumption of *Yarrowia lipolytica* at atmospheric pressure (♦) and in hyperbaric reactor under pressures of 1 bar (■), 2 bar (▲), 3 bar (×), 4 bar (□), 5 bar (◊) and 6 bar (Δ).

The results described above are in accordance with the previous work of Lopes et al. (2008), in which no cellular activity inhibition by pressure was detected in batch cultures of *Y. lipolytica* in culture media without glucose. Also, Belo et al. (2005) observed for semi-continuous cultures of *Saccharomyces cerevisiae* that an increase of pressure up to 10 bar had no metabolic impact in the cells. Aguedo et al. (2005) reported that the application of 5 bar air pressure stimulated the cell growth of *Y. lipolytica* W29 comparatively to atmospheric growth conditions.

In experiments under atmospheric pressure and 1 bar of air pressure, glucose was not totally consumed. The raise of air pressure up to 6 bar led to a completely consumption of glucose.

The use of pressure might be exploited to improve the biomass productivity of *Y. lipolytica* W29 (Table 1). An increase of air pressure up to 6 bar led to a 4.1-fold improvement in biomass productivity comparatively to atmospheric pressure. This result is in accordance with previous work of Pinheiro et al. (2000), in which the productivity in biomass of *K. marxianus* CBS 7894 was increased with the increase in air pressure up to 6 bar. Also, Charoenrat et al. (2006) observed that the cell mass productivity of *Pichia pastoris* can be improved by application of increased air pressure. However, for *S. cerevisiae*, Pinheiro et al. (1997) reported that an increase of 6-bar air pressure led to a decrease on biomass productivity for a batch mode of operation. This shows that microorganisms react differently to the air pressure rise, depending also on other culture conditions.

Table 1 Changes in biomass yield, specific growth rate and productivity with air pressure in batch experiments.

Pressure (bar)	$Y_{x/s}$ (g biomass/g glucose) (%)	μ (h^{-1})	P (g biomass/l·h)
Control	53.3	0.09	0.25
1	34.7	0.18	0.17
2	70.2	0.19	0.45
3	96.7	0.23	0.62
4	104.1	0.26	0.71
5	117.9	0.28	0.77
6	121.1	0.31	1.02

The specific growth rate of *Y. lipolytica* was clearly enhanced by the increase of air pressure. An increase of 6-bar led to a 3.4- and 1.7-fold increase in specific growth rate under atmospheric pressure and 1 bar, respectively. Due to the high oxygen mass transfer rate, the cells have more oxygen in the medium giving higher growth rates, and less time is necessary to obtain maximum cell concentration. Belo et al. (2005) reported that an increase of air pressure up to 6 bar led to a 1.8-fold improvement in the specific growth rate of *S. cerevisiae*.

Also, Pinheiro et al. (2000) observed that an increase of 4-bar led to a high increase in specific growth rate for *K. marxianus*.

Biomass yield was also enhanced by air pressure rise. With 6 bar air pressure biomass yield was 121.1 % whereas at 1 bar it was 34.7 %. At values of air pressure up to 2 bar glucose was not totally consumed, probably due to oxygen limitation. An increase of the yield at 6 bar of 56 % and 71 % was obtained compared with the experiments under atmospheric pressure and 1 bar, respectively.

It is clear from these results that pressure had no inhibitory effects on the growth of this yeast strain. An increase of air pressure up to 6 bar might successfully be applied to the improvement of the biomass production of *Y. lipolytica* W29.

Yeast cells were observed by optical microscopy and was noted that the cells displayed a typical oval form in all assays up to 6 bar (data not shown). The results demonstrated that cell exposure to increased air pressure did not induce hyphae formation.

Pressure effect on antioxidant enzyme activities

To examine the effects of oxygen toxicity on yeast cells, with the increase in oxygen partial pressure, the changes of cellular antioxidant enzyme activities under different air pressures were determined. Figure 2 presents the data of the catalase and SOD specific activities, measured at the end of the cell cultivation under hyperbaric conditions.

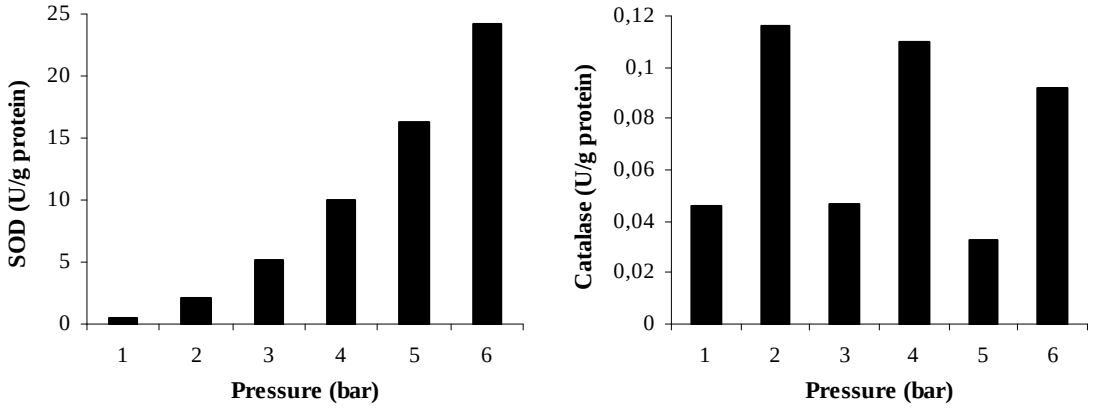

Fig. 2 Effect of air pressure on superoxide dismutase and catalase specific activities, in the final batch cell cultures (approximately 30 h of growth).

Superoxide dismutase specific activity was induced by hyperbaric air to a maximum of 6 bar. An increase of the SOD specific activity at 6 bar of 53.4-fold was obtained compared with the experiments under 1 bar. This shows the ability of *Y. lipolytica* cells to respond to the increase of reactive oxygen species formation because of hyperoxygenation. The SOD induction showed the cell sensitivity to high oxygen concentrations. However, as no cell growth inhibition was observed under pressurized conditions, it is quite safe to state that the cells of the strain used can cope with air pressure values up to 6 bar.

The influence of total air pressure on the catalase activity is not clear, thus it seems that this enzyme plays a minor role in the defensive mechanisms against the oxidative stress, for *Y. lipolytica*.

These results demonstrate that the raise of air pressure could be also applied to SOD production, once it is most induced.

Pressure effect on lipase production and pre-adaptation

In order to investigate the influence of a pre-adaptation phase of cells to hyperbaric conditions on the lipase production by *Y. lipolytica* cells under increased pressure, assays

were conducted in the pressurized bioreactor in which cells were pregrown on the bioreactor at normal and increased pressure following by a lipase production phase at normal and increased pressure.

The increase of total air pressure influences enzymatic activity, as demonstrated by previous work of Lopes et al. (2008). The authors observed that an increase of OTR by raising air pressure up to 8 bar resulted in an increase of the lipase production by *Y. lipolytica* cells grown at atmospheric pressure. In this work, an increase of the lipase activity and lipase productivity at 5 bar of 1.8-fold and 3.7-fold, respectively, was obtained compared with the experiments under 1 bar, independently of the pressure conditions used in the inocullum preparation (Fig. 3A).

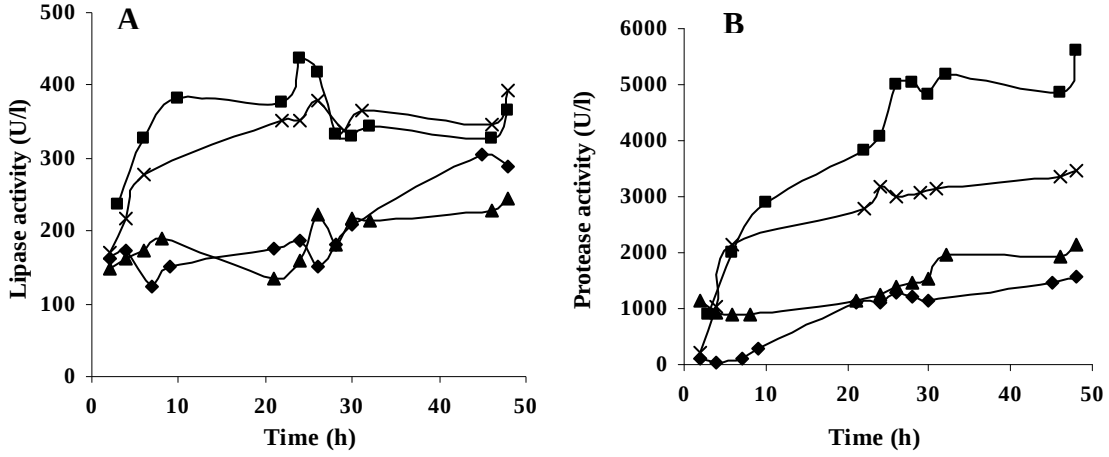

Fig. 3 Extracellular lipase (A) and protease (B) activities profiles by *Yarrowia lipolytica* in the pressurized reactor at different air pressures of growth and production, respectively: 1 bar and 1 bar (♦), 1 bar and 5 bar (■), 5 bar and 1 bar (▲) and 5 bar and 5 bar (×).

For the range of air pressure values applied, the pre-adaptation phase of cells to hyperbaric conditions did not improve the lipase production. The lipase production at 5 bar with cells pregrown at the same air pressure was similar to the obtained with grown cells under atmospheric pressure. Therefore, it can be concluded that the *Y. lipolytica* cells can quickly respond and adapt to hyperbaric conditions and no need of long phases of hyperbaric stress adaptation is needed.

Besides lipase production, the production of other enzymes, such as proteases, by *Y. lipolytica* strains has been reported (Puthli et al., 2006). Figure 3B shows the results of monitoring protease secretion along time, using azocasein as substrate. During the first hours of culture the protease activity was low, increasing gradually until the end of the cultivation time, suggesting that the decrease of the medium pH (data not shown) favours the production of an acid protease by yeast.

The highest value of protease production was found for the 5 bar assays, whereas in the experiments carried out under 1 bar its concentration in the medium was lower. The presence of protease in culture medium can influence the production kinetics of lipases since the prolonged time of fermentation can lead to the loss of product due to its decomposition. However, in this work, highest value of protease production was reached at the same air pressure (5 bar) that the maximum lipase productivity was obtained. Probably, lipase activity might be improved even more if protease secretion into the medium is inhibited by a chemical agent.

4 Conclusions

For the experimental conditions used in this work, air pressure rise up to 6 bar proved to be applicable to the batch cultivation of *Yarrowia lipolytica* W29. It has been demonstrated that the use of air pressure has positive effects on the growth behaviour of yeast and that air

pressure may be a way of increase the specific growth rate, leading to high biomass productivity. For *Y. lipolytica*, an increase of air pressure up to 6 bar led to a 4.1-fold improvement in biomass productivity comparatively to atmospheric pressure.
To protect against the damage caused by oxidative stress, cells possess a number of antioxidant enzymes and repair activities, most of which are expressed al low levels during normal growth. In spite of the SOD induction, air pressure rise did not inflict oxidative stress to the cells. Yarrowia lipolytica W29 adapt rapidly to hyperbaric conditions, thus this conditions can be imposed to cultures of this strain was a way of preventing oxygen limitation to cell growth and as a mean of several enzymes production improvement such as lipases, proteases and SOD.

Topic: Suitable conference topic — Integration of life sciences & engineering

Abstract

Yarrowia lipolytica has been intensively used in our research group to develop different bioprocesses based in the ability of this yeast to use hydrophobic substrates. Work has been focused in the optimization of the production of γ-decalactone and lipase, and to degrade and detoxify olive oil wastewater producing simultaneously high-value compounds, such as enzymes. Studies of the oxygen mass transfer phenomenon in biphasic media was also conducted and applied to select the most adequate oxygenation conditions for bioprocesses. Application of increased air pressures has also been proven to be an effective mean to improve oxygen transfer rate into *Y. lipolytica* cultures.

1 Introduction

The ascomycetous yeast *Yarrowia lipolytica* is a natural dimorphic fungus, which forms yeast cells, pseudohyphae and septate hyphae. The morphology is determined both by growth conditions (aeration, carbon and nitrogen sources, pH, etc) and by the genetic background of the strain (Barth and Gaillardin, 1997).

Y. lipolytica is one of the more intensively studied non-conventional yeast species. This microorganism is not only of interest for fundamental research, but also for biotechnological applications (Barth and Gaillardin, 1997). As it is considered as non-pathogenic and as GRAS by the American Food and Drug Administration, this yeast has been used in several industrial applications like production of single cell protein, peach flavour and citric acid (Beckerich et al., 1998). The range of substrates used by *Yarrowia lipolytica* include alkanes, fatty acids, organic acids, proteins and some sugars, which also contributes to the interest of this yeast (Fickers et al., 2005).

In our laboratory we have been exploring the abilities of this yeast in three main different fields: optimization of a peach-like aroma compound production; optimization of lipase production using hyperbaric conditions; and valorization of olive mill wastewater (OMW) by producing high-value compounds while degrading this waste.

2 Aroma production

γ-Decalactone is a peach-like aroma compound well known in several food and beverages, reason why the food industry has a high interest in its biotechnological production. One of the better known applications is the biotransformation of ricinoleic acid catalysed by yeasts with GRAS status, conferring a natural label to the aroma, which is very important, considering the increasing health- and nutrition-conscious lifestyles.

* Corresponding author. Tel + 351-253604413. E-mail:ibelo@deb.uminho.pt

Ricinoleic acid (12-hydroxy-octadec-9-enoic acid) is a hydroxylated C_{18} fatty acid that in its esterified form is the major constituent (about 86%) of castor oil, making it an abundant compound.

The yeast *Yarrowia lipolytica* is able to carry out the biotransformation of ricinoleic acid into γ-decalactone. This process involves the substrate degradation through the peroxisomal β-oxidation (Figure 1), leading to the formation of 4-hydroxydecanoic acid, which cyclises into γ-decalatone (Blin-Perrin et al., 2000).

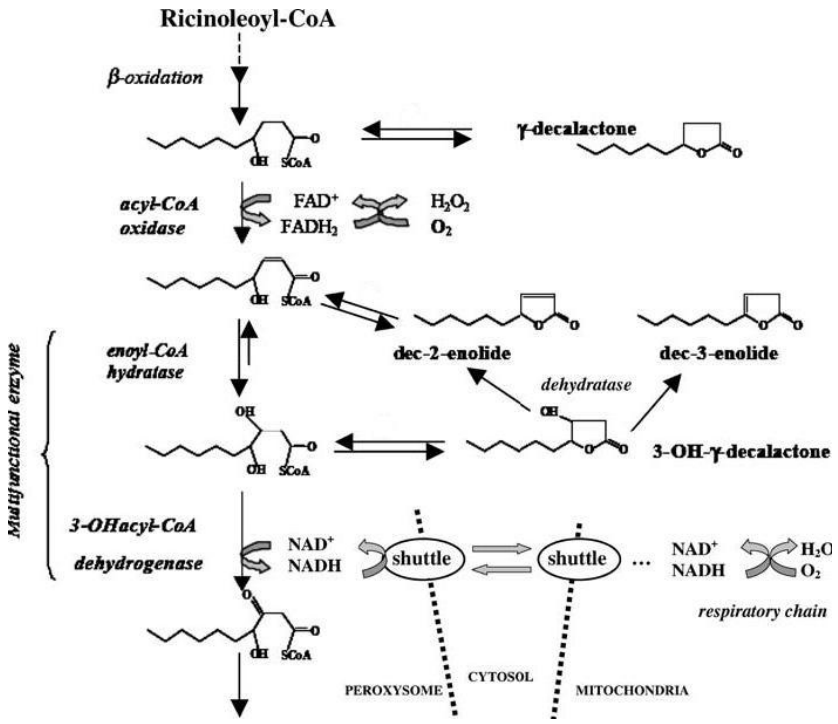

Figure 1 - β-Oxidation cycle from 4-hydroxydecanoic acid (the direct precursor of γ-decalactone) during the degradation of ricinoleoyl-CoA.

The production of γ-decalactone has been intensively investigated in order to better understand the all process and optimize it (Aguedo, 2002; Waché et al., 2001). Oxygen availability in the medium is a determining factor in the process, intervening in the control of the peroxisomal β-oxidation pathway. Thus, work has focused in the optimization and modelization of oxygen mass transfer in this complex multi-phase system composed by an aqueous and an organic phase as well as a gaseous and a solid phase (Gomes et al., 2007).

Oxygen mass transfer in the biphasic system

Oxygen transfer rate (OTR) in a system is a function of the oxygen volumetric mass transfer coefficient (k_La) and the oxygen solubility in the medium. For a specific bioreactor and medium, it is possible to increase k_La and, consequently, OTR, using high agitation and aeration rates. However, this causes high power consumption, significantly increasing operation costs. The addition of a second, water-immiscible phase, in which oxygen has a higher solubility, has been proposed by several authors as an alternative mean of OTR improvement. Usually, experiments described in the literature use a hydrocarbon or a perfluorocarbon (PFC) as an inert dispersed phase in the aqueous medium. In the system herein described, the organic phase is the substrate used by the cells and not an inert compound used with the only purpose of increasing OTR. The effects of adding a second liquid organic phase on k_La may change (k_La values may increase, decrease, or remain constant) depending on the nature of the organic compound and the operating conditions (Dumont and Delmas, 2003). So, in order to take into account, not only the effect of the

organic phase, but also the effect of surfactant and operating conditions (agitation and aeration rates) on k_La, an empirical correlation was proposed, assuming that the two liquid phases behave as a single homogeneous phase (Eq. 1).

$$k_L a = 243 \cdot \left(\frac{P_g}{V}\right)^{0.6} \cdot (v_s)^{0.6} \cdot (1 - X_{RM})^3 \cdot (1 - X_{Tween})^{-141} \quad \text{Eq. (1)}$$

Where P_g represents the power input of the aerated bioreactor; V, the bioreactor working volume; v_s, the superficial gas velocity through the bioreactor; X_{ORG}, the fraction of the organic phase; X_{Tween}, the fraction of surfactant; and δ, α, β and γ are numerical constants.

This correlation enables the prediction of k_La as a function of operating conditions and organic phase composition for the biotransformation system (Gomes et al., 2007).

An interaction effect between the organic phase and the surfactant was found: the organic phase increased k_La in the absence of the surfactant but had an opposite effect when Tween 80 was available in the medium. This is due to a change in the surfactant at the gas-liquid interface because when an organic phase is added to aqueous solutions with Tween 80, a new distribution of surfactant between interface and bulk phases is originated. The presence of surfactant inhibits the mass transfer because its accumulation at the gas-liquid interface causes a decrease in the liquid surface elements renewal (turbulence near the interface) and it implies that oxygen concentration in the liquid phase zone, near to the gas-liquid interface, is higher than the oxygen concentration in the bulk of the liquid phase. Therefore, the driving force of the absorption process decreases producing the same decrease in the absorption rate (Goméz-Díaz et al., 2008).

Influence of oxygen transfer rate on the aroma production

The influence of k_La on γ-decalactone production by the biotransformation of methyl ricinoleate (ricinoleic acid source) was proven through the performance of several experiments at different operating conditions, in a 2-L stirred bioreactor. A maximal aroma compound production (141 ± 21 mg L^{-1}) was achieved for a k_La of 70 h^{-1}, obtained at 27ºC with agitation and aeration rates of 400 rpm and 0.6 vvm, respectively, 1% (v/v) methyl ricinoleate and a cellular density of 1.4×10^8 cells mL^{-1}.

Previous works in the group have demonstrated that hyperbaric air can be successfully applied to yeast cultivation as a way of improving the OTR to aerobic cultures (Belo et al., 2003). Based on this, the effect of increased air pressures on the oxygen mass transfer improvement for the production of γ-decalactone was studied (Aguedo et al., 2005). Essays were carried out in a 600-mL stainless steel high-pressure bioreactor. Air pressures of 1 bar (atmospheric pressure), 5 bar and 10 bar were applied on the cell growth and on the biotransformation of ricinoleic acid. The application of 5 bar accelerated cell growth, compared to the atmospheric conditions. However, when 10 bar was used, growth was inhibited after 10 h exposure, suggesting hyperbaric stress on the cells.

Besides γ-decalactone, also other compounds (3-hydroxy-γ-decalactone, dec-2-en-4-olide and dec-3-en-4-olide) proceeding from the direct precursor of γ-decalactone (4-hydroxydecanoic acid) were analyzed (Figure 1).

Results revealed that oxygen plays an important role on the enzymes that control the β-oxidation metabolic pathway. Low oxygen concentrations in the medium induced the control of the β-oxydation pathway by acyl-CoA oxidase and therefore, an accumulation of γ-decalactone occured. On the contrary, when higher oxygen levels were used, the control of the pathway was carried out by 3-hydroxyacyl-CoA dehydrogenase, resulting in an accumulation of 3-hydroxy-γ-decalactone.

Effect of two different substrates and its concentrations on the aroma production

Since oxygen is more soluble in the organic phase than in the aqueous phase, increasing oil concentration leads to an oxygen mass transfer improvement.

We investigated the influence of two different ricinoleic acid sources (castor oil and methyl ricinoleate) at several concentrations, on the production of γ-decalactone by *Y. lipolytica* (Gomes et al., 2008). Experiments were carried out in 500-mL flasks. The highest amounts of γ-decalactone (around 2 gL^{-1}) were achieved with oil concentrations of 3% and 5% (v/v) for each substrate, but as the process was quite long, the productivity of the process was small (10 to 14.5 mg L^{-1} h^{-1}). In order to improve this, experiments with 3% (v/v) methyl ricinoleate were carried out in a 2-L stirred bioreactor, under different agitation and aeration rates. The highest concentration and productivity achieved for the aroma production was approximately 1 g L^{-1} and 87.6 mg L^{-1} h^{-1}, respectively, with an agitation rate of 600 rpm and 5 L min^{-1} of aeration (Figure 2). However, contrary to the essays in flask, in bioreactor, high concentrations of 3-hydroxy-γ-decalactone were produced for all conditions tested, reaching a maximal value of 8 g L^{-1}, using 600 rpm and 5 L min^{-1} of agitation and aeration rates, respectively. The accumulation of this compound and of γ-decalactone were directly proportional to the increase of OTR in the medium. Work now proceeds in the optimization of the OTR conditions to improve the overall process.

3 Lipase production

Lipases, triacylglycerol hydrolases, are an important group of biotechnologically relevant enzymes finding vast applications in food, dairy, detergent and pharmaceutical industries.

Due to the facility of single cell use and to the high secretion ability, *Yarrowia lipolytica* has revealed to be an interesting and alternative organism to be used in lipase production (Pignede, 1998).

The increase of lipase productivity during the fermentation process is of great importance since lower costs of production could promote new industrial applications. The extracellular lipase production is affected by different environmental factors such as pH, temperature, medium composition, aeration, agitation and proteases present in the medium. Moreover, the presence of some compounds (i.e. fatty acids, triglycerides and surfactants) has often shown to induce lipase secretion (Dalmau et al., 2000).

Effect of medium composition and pH on lipase production

Lipase production by the strain *Y. lipolytica* W29 was previously studied through a experimental 2^{4-1} fractionated factorial design (Lopes et al., 2007). A culture medium composed by YNB without aminoacids, at pH 7.2, with an arabic gum concentration of 0.5% (w/v) promoted the highest values of lipase activity (247 U L^{-1}) and productivity (10.7 U L^{-1} h^{-1}). The presence of Tween 80 revealed to have a negative effect on lipase activity. Contrary to other studies (Dalmau et al., 2000; Fickers et al., 2003), the increase of olive oil concentration did not improve lipase activity and the presence of glucose did not inhibit the enzyme production.

Effect of increased air pressures on cell growth and morphology and on lipase production

The amount of available oxygen to *Y. lipolytica* is an important parameter since this strain is strictly aerobic. In order to obtain a further insight on the influence of moderate total air pressure both on yeast growth and on lipase production, *Y. lipolytica* was grown in 300-mL cylindrical stainless steel pressurized bioreactor where the variation of OTR with pressure could be modeled (Lopes et al., 2008). Despite the OTR increase of 2.3-fold when the pressure varied from 4 bar up to 8 bar, no differences were observed in the cellular growth.

An increase of the lipase activity at 8 bar (550 U L^{-1}) of 5.5-fold and 2.3-fold was obtained compared with the experiments under atmospheric pressure and 4 bar, respectively. The rise of the total air pressure from 1 bar up to 8 bar, led to a 4.8-fold improvement in the lipase productivity (11 U L^{-1} h^{-1}). Besides lipase production, protease secretion into the medium was also observed. Its activity was inhibited by air pressure of 8 bar, indicating that pressure has different effect on lipase and protease activities.

Simultaneously, the effect of hyperbaric air in the morphology of this dimorphic yeast has been investigated using an automatic image analysis technique. It was observed that cell exposure to increased air pressure did not induced hyphae formation but led to a cell size decrease for the 8 bar cultures (Lopes et al., 2008).

Lipase induction by castor oil and methyl ricinoleate

Besides olive oil, other compounds can be used to induce lipase activity in *Y. lipolytica*. This is the case of the oils used in the biotransformation process of aroma production mentioned above. Lipase activity was detected in experiments with different concentrations of both ricinoleic acid sources, castor oil (CO) and methyl ricinoleate (MR) (Table 1).

Table 1 – Maximum lipolytic activity obtained for different operating conditions.

Experiments	[Substrate] (% v/v)	Maximum lipolytic activity (U L^{-1})
w/ washed cells	[MR] = 3	19 ± 3.9 (169.5 h)
w/o washed cells	[MR] = 3	105 ± 4.8 (271.5 h)
	[CO] = 3	42 ± 7.1 (192 h)

Methyl ricinoleate seemed to be more adequate than castor oil to induce lipase production, since the lipolytic activity was 2.5-fold higher with MR than with CO, for the conditions tested. Moreover, the enzyme production seems to be significantly affected by the hydrophobic characteristics of the cell, since a higher lipase activity was found when the biotransformation was carried out with cells that did not suffer the washing pre-treatment.

4 Olive mill wastewater

The ability of hydrophobic substrates use by *Yarrowia lipolytica* strains has been used not only to develop industrial biporocesses but also to solve environmental problems, such as bioremediation and lipidic wastewaters treatment (Fickers et al., 2005). Olive mill wastewater (OMW) is an example of those environmental problems resulting from the olive mill industry. OMW is a dark-colored stable emulsion effluent, characterized by a high polluting load.

The organic fraction of OMW includes sugars, tannins, polyphenols, polyalcohols, pectins and lipids, resulting in high values of chemical oxygen demand (COD). Thus, OMW can represent a possible renewal resource that might be a basis for fermentation processes.

Yeast species such as *Yarrowia lipolytica* can grow well in OMW media, consume the organic material and, simultaneously, produce biomass and other valuable products like enzymes and organic acids (D'Annibale et al., 2006), contributing for the valorization of OMW, which is the aim of the current investigation in our laboratory. Thus, in a first stage, work focused on the potential use of OMW as a culture medium for different *Yarrowia lipolytica* strains; i.e. their ability to grow and to produce high-value compounds, such as enzymes (e.g.: lipases), while degrading and detoxifying this waste was evaluated. For this purpose, different OMW from different regions of Portugal have been collected and characterized. Although all strains were able to grow in OMW based media without dilution, to consume almost all of the sugars present in the media and to significantly reduce COD values, the most adapted strains were selected.

Investigation now proceeds on the optimization of OMW fermentation process on a lab-scale bioreactor.

Topic: Integration of life sciences & engineering

Abstract

Biochemical processes important to cell viability depend on the electric potential through cell membrane. The application of an electric field to a living cell might promote metabolic responses and modification of cell membrane potential. In this work the effects of the application of electric field in the yeast *Yarrowia lipolytica* was investigated analyzing its physiology (cell growth, glucose consumption and lipase activity) and population morphology through digital image analysis. Electrical potential promoted increased lipase productivity formation of hyphaes and maintained cells viability.

1 Introduction

Yarrowia lipolytica is an aerobic microrganism capable of producing important metabolites with an intense secretory activity, which justifies efforts to use it in industrial processes (as a biocatalyst), in molecular biology and in genetics studies. It has been considered an adequate model for dimorphism studies in yeasts, since it has an efficient system for genetic engineering transformation, and it is easy to distinguish between its morphological forms, in contrast to *S. cerevisiae*, which does not produce true filaments and exhibits pseudo-hyphae growth under nitrogen-limited conditions. The yeast-to-mycelium transition is associated with unipolar growth, asymmetric division, large polarly located vacuoles and repression of cell separation after division (Cruz *et al*, 2000).

Responses of living cells to electrical signals have been used, for example, in biotechnology (Bartlett et al., 1997), bioanalytical techniques (Lötzbeyer et al., 1996; Ci et al., 1997; Gheorghiu and Asami, 1998) and medical purposes (Chen et al., 1998; Veiga et al., 2005). Araujo et al. (2004) reported oscillation on culture of *S. cerevisiae* when electrical potential was imposed to a batch culture. Additionally, visual observation of cells using optical microscopy indicated smaller cell sizes in cultures submitted to pulsing electrical potential as compared to control experiments.

The aim of this work is to investigate the effects of the application of an electric field in the yeast *Yarrowia lipolytica* analyzing its population physiology (cell growth, glucose uptake and lipase activity) and morphology (monitored by digital image analysis and fluorescence microscope).

2 Experimental Methods

2.1 Strain, media, culture and experimental conditions

A wild type strain of *Yarrowia lipolytica* (IMUFRJ 50682) was employed and kept at 4ºC on YPD-agar medium. For growth conditions, cells were cultivated at 28ºC in a rotary shaker at 160 rpm, in flasks containing YPD medium (w/v: yeast extract (Oxoid) 1%; peptone (Merck),

* Corresponding author. Tel + 55-21-2562-7637. E-mail:ofelia@eq.ufrj.br

2%; glucose (Isofar), 2%). The cells were inoculated in a bioelectrochemical reactor containing modified YPD medium (0.64% peptone, 1% yeast extract, 2% glucose).

The bioreactor (Multigen, New Brunswick Scientific Co., EUA), with volume of 2 l, contains aeration system, magnetic stirring and control of temperature, provided with two turbines and two baffles. An oxygen probe (Lutron DO-5510, Lutron Electronics Co., Inc) was used to measure the concentration of dissolved oxygen in the bioreactor. The supply of oxygen was conducted with filtered air (Advantec, Toyo Roshi Kaisha, Japão with porosity 0,2 μm) using a system of submerged aeration through 12 holes in the agitation shaft with 7 mm in diameter located 1.82 cm from the vessels' bottom. Stirring speed of 550 rpm and airflow rate (Q) of 1.5 $dm^3.min^{-1}$ were used.

In cell growth experiments, the value of applied potential was 0.75 V_{SCE}, based on Araujo *et al.* (2004). To apply this eletrical potential, a potentiostat (PG-01 Ohnimetra Instruments) was used with working electrode and counter-electrode of platinum, and reference electrode (SCE).

2.3 Biochemical Methods

- Cell growth was followed by optical density measurements at 570 nm. Absorbance values were converted to mg d.w./mL using a factor previously determined experimentally.

- Lipase activity was estimated by variations on absorbance at 410nm in spectrophotometer (Hach, DR4000UV) due to oxidation of p-nitrophenyl laurate (p-NFL) (supplied by SIGMA) with a concentration of 0.162 mg / mL in potassium phosphate buffer (0 , 05M), pH 7.0 (Pereira-Meirelles, 1997).

- Glucose comsumption: Glucose was quantified by the method of glucose oxidase (enzyme kit, Human GmbH, Germany).

2.4 Microscopic Methods

- Morphological analysis

Cell morphology was observed along the batch run using a Nikon optical microscope with 1,000 X magnification, in both control and stress conditions. Traditional tools generally used for image enhancing were employed. The RGB image was decomposed into its respective channels, and the green channel was employed in the image treatment steps (Kawasse *et al.*, 2003). A grayscale intensity image was created and a combination of bottom and top hat filtering was used to enhance image contrast. A binarization step was performed followed by the elimination of border structures and a hole-fill procedure was carried out. Application of morphological operations, such as erosion (to remove small debris) and reconstruction, gave the final image. This image treatment was performed in MATLAB v.6.1 (The Mathworks Inc., The Mathworks Inc.) environment.

In order to extract cells' individual properties, their characteristics were determined using image analysis of the labeled objects: *area* is the area of the projected surface of the object on the plane of vision; *hyphal length* and *hyphal width* were determined as the maximum Feret diameter (FMax) and minimum Feret diameter (FMin), respectively. The Feret diameter is given by the distance between two parallel tangents in any given direction (Kawasse *et al.*, 2003). Elongation is given by the ratio between *hyphal length* and *hyphal width*:

$$Elongation = \frac{F_{Max}}{F_{Min}}$$

- Viability analysis

Fluorescent dye of acridine orange was used for the simultaneous distinction of live and dead cells (dead cells give out red or orange fluorescence and living cells yellow-green; 180 µM AO, pH 6). Cell counting was done in a Nikon optical microscope with 1,000 X magnification.

The procedure for the treatment of the cells consists in two washes of cells with phosphate buffer (0,05M) followed by resuspension of cells in 0.5 ml of phosphate buffer (0,05M) with 0.5 ml of acridine orange(0,5M). The cells were kept in darkness for 20 minutes.

3 Results and Discussions

3.1 Biochemical Responses

Table 1 presents the results of maximum specific growth rate (µ) and glucose consumption rate ($-dS/dt$) of both stress and control conditions.

Table 1: Specific growth rate (µ) and glucose consumption ($-dS/dt$) of *Y. lipolytica* cultivated with and without electrochemical potential.

Stress	µ (h^{-1})	$-dS/dt$ (g/l/h)
No	0.32±0.04	0.63±0.04
Yes	0.30±0.04	1.03±0.04

It is possible to observe that µ values are similar for both experiments (with and without electrochemical stress). However, substrate consumption ($-dS/dt$) increases around 61% with application of electrochemical potential. It is proposed that the applied electrical potential increases cell's metabolism and the consumed glucose might have been directed to another metabolite.

Figure 1 presents lipase prodution by *Y. lipolytica* under eletrochemical stress conditions and control conditions (no stress).

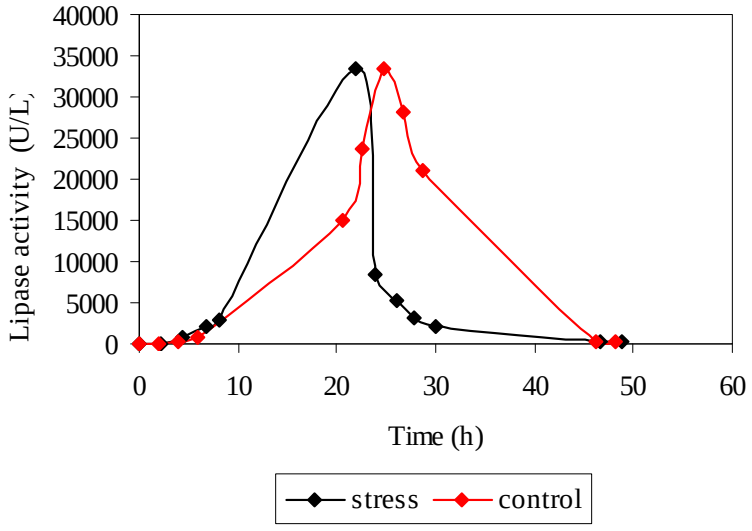

Figure 1. Lipase production with and without electrochemical stress.

It is possible to observe that the activity peaks were very close in intensity, but the application of electrical stress advanced lipase's activity peak (peak value was reached

earlier). Therefore, the lipase productivity, calculated in Table 2, is 13% higher with electrochemical potential application.

Table 2: lipase productivity by *Y. lipolytica* with and without electrochemical stress.

Stress	Produtivity (U/l*h)
No	1353.5
Yes	1526.4

3.2 Morphological Responses

The morphological response of cell exposure to electrochemical stress is displayed in Figure 2. There is a subtle tendency for the formation of more elongated cells, or hyphaes, with the application of electric potential. This tendency might be the result of the cell defence system to the stress condition implyed to the cells.

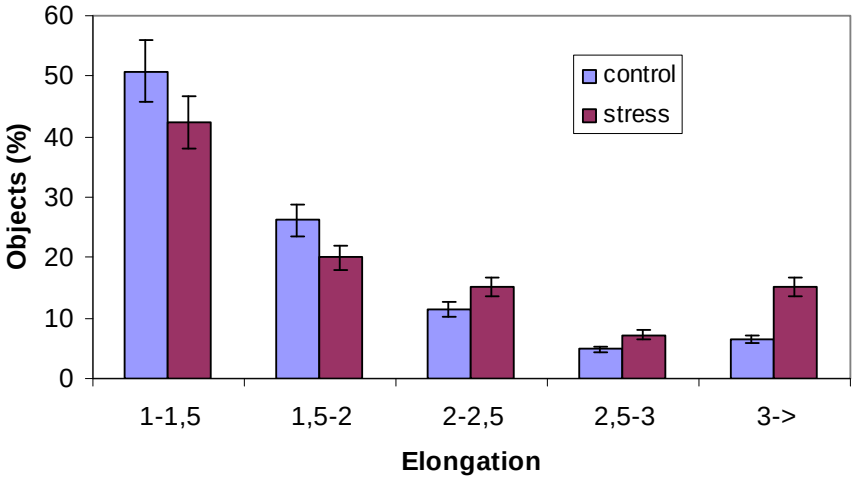

Figure 2. Elongation factor distribution for control and stressed experiments.

In order to evaluate if the stress condition had also affected the viability of cells, a staining method distinguishing dead and living cells was performed. Figure 3 presents the results during control and stress experiments.

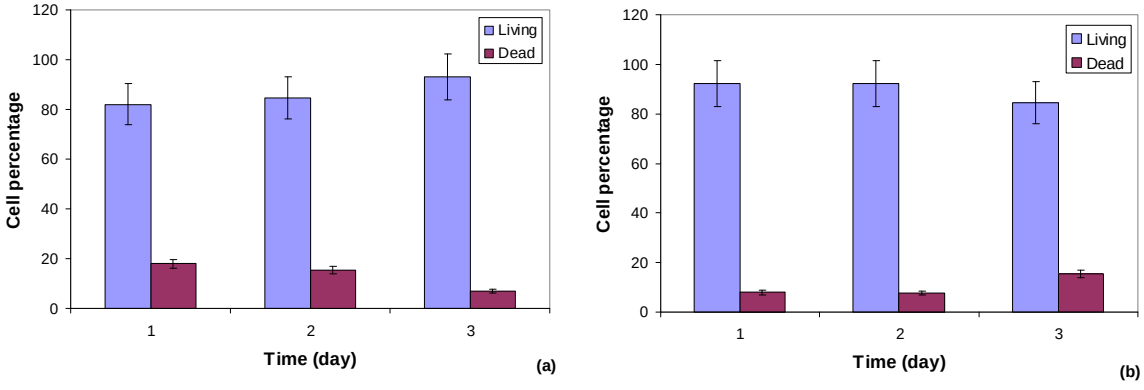

Figure 3. Percentage of living and dead cells during the experiments: (a)control and (b) under stress.

According to Figure 3, it is possible to notice that when cells are subjected to electrical stress there is no significant difference in their viability as compared to a control experiment. The maintenance of-cell's viability increases the interest in this type of stress.

4 Conclusions:

This work reports the evaluation of physiological and morphological effects of applied electrical potential to a culture of *Yarrowia lipolytica*. Specific growth rates (μ) are similar for experiments with and without electrochemical stress, but substrate consumption (-dS/dt) increases around 61% with application of electrochemical potential.

Electrochemical stress advanced time of lipase's activity peak and its productivity increased 13%. A cell's viability study indicates that there is no significant difference of viability when cells are subjected to electrochemical stress when compared to the control conditions, showing that this stress condition does not compromise the cells. On the other hand, the application of this stress modified cell morphology, giving a more elongated aspect. Such response is attributed to cell's defense system.

Keywords: Liquid-liquid extraction, green fluorescent protein, nisin
Topic: Integration of life sciences & engineering

Abstract

In the biotechnology field, it has been suggested that extractions in two-phase aqueous complex-fluid systems can possibly be used instead of, or as complementary processes to, the more typical chromatographic operations, to reduce the cost of the downstream processing of many biological products (Lam et al., 2004; Mazzola et al., 2006). This method offer attractive conditions to be applied in this study, thereby two-phase systems can be exploited in separation science for the extraction/purification of desired biomolecules directly on the culture medium (Mazzola et al., 2008). This study aimed to evaluate the aqueous two phase system (ATPS) composed by a nonionic surfactant, Triton X-114 (TX), in presence or absence of electrolytes, to separate two interesting biomolecules: nisin and recombinant green fluorescent protein (GFP). Results indicated that nisin partitions preferentially to the micelle rich-phase, with significant antimicrobial activity increase (up to 10-fold). GFP partitioned evenly between the phases in TX system without electrolytes.

1 Introduction

The industrial production of proteins and other biomolecules depend significantly on the extraction/purification processes. The development of techniques and methods for separation and purification of proteins has been essential for many advances in biotechnology (Wilcheck et al., 1999). In this sense, one of the techniques that can be considered promising is liquid-liquid extraction. Various liquid-liquid extraction methods that use different types of two-phase aqueous complex-fluid systems have been proposed to address a wide variety of separation needs in the chemical, biotechnological, and environmental fields. In general, these methods offer the possible advantages of versatility, scalability, cost effectiveness, and environmental friendliness compared to the conventional methods that they may replace. In the biotechnology field, it has been suggested that extractions in two-phase aqueous complex-fluid systems can possibly be used instead of, or as complementary processes to, the more typical chromatographic operations, to reduce the cost of the downstream processing of many biological products (Lam et al., 2004; Mazzola et al., 2006).

In particular, two-phase aqueous micellar systems, formed by some surfactants at certain conditions, have been proposed as an attractive option, to be used in bioseparations (Liu et al., 1998). In these systems an aqueous surfactant solution, under the appropriate solution conditions, spontaneously separates into two predominantly aqueous, yet immiscible, liquid phases, one of which has a greater concentration of micelles than the other (Liu et al., 1998).

The difference between the physicochemical environments in the micelle-rich phase and in the micelle-poor phase forms the basis of an effective separation and makes two-phase aqueous micellar systems a convenient and potentially useful method for the separation, purification, and concentration of biomaterials (Liu et al., 1996).

This method offer attractive conditions to be applied in this study, thereby two-phase systems can be exploited in separation science for the extraction/purification of desired biomolecules directly on the culture medium (Mazzola et al., 2008).

Nisin is an extracellular antimicrobial peptide, discovered in 1928, its utilization are approved by Food and Drugs Administration (FDA) (Hansen, 1994; Vessoni Penna and Moraes, 2002), meeting the requirements of safe food with fewer chemical additives (Chol et al., 2000). This peptide has large antimicrobial activity spectrum against Gram-positive bacteria and their spores (Delves-Broughton et al., 1996). Other applications of nisin include dental care products (Turner et al., 2004), pharmaceutical products such as stomach ulcers and colon infection treatment and potential birth control (Aranha et al., 2004; Dubois, 1995). Recently the optimization of nisin production has been reported. Jozala and co-workers (2005, 2007) and Vessoni Penna and co-workers (2005, 2006) studied nisin expression using different media compounds based on skimmed milk diluted with synthetic media (MRS and M17) and with nutrients added. Diluted skimmed milk was observed to be the best culture media for nisin production and activity by *L. lactis*.

The GFP, expressed by *Escherichia coli* DH5-α, is widely applied with as biossensor and can be detected by spectrofluorometry or using hand UV lamp, it has became a versatile tool for a variety of biotechnological uses and as a potential biological indicator, for preservation of manufactured and processed products (Vessoni Penna et al., 2004). GFP is an excellent biosensor due to its ability to be easily monitored in a wide variety of applications. Enzymes and proteins have been used as biological indicators to evaluate the immediate efficacy of industrial procedures, such as blanching, pasteurization, and disinfection treatments, as well as to monitor the satisfactory preservation of a product subjected to disinfection or sterilization.

This study aimed to evaluate the aqueous two phase system (ATPS) composed by a nonionic surfactant, Triton X-114 (TX), in presence or absence of electrolytes, to separate two interesting biomolecules: nisin and recombinant green fluorescent protein (GFP).

2 Materials and Methods

The biomolecules were obtained from commercial and produced way, standard nisin was provide by Nisin™ (Sigma, St. Louis, MO) and GFP expressed by transformed *E. coli*; produced nisin was skimmed milk fermented by *L. lactis* and GFP was complex media fermented by *E. coli* DH5-α. The system was composed by 2% w/w TX with and without $MgSO_4$ or $(NH4)_2SO_4$. The phase diagram of the TX in buffer was obtained by the cloud-point method. Buffered solutions of the 2%TX with or without electrolytes, each with a total volume of 3 mL, were prepared in graduated 10-mL test tubes. Each solution was placed in a thermo-regulated device set at a temperature of 36.2ºC for 2h to attain partitioning equilibrium. Nisin activity was determined by agar diffusion with *L. sakei* as bioindicator. GFP concentration was determined by fluorimetry.

The biomolecules were purchased and biosynthesized, standard nisin was provides by Sigma (St. Louis, MO) and GFP was expressed by modified *E. coli* and purified; produced nisin was skimmed milk fermented by *L. Lactis*. The initial concentration of nisin in each system was 3 log AU/mL, and the initial concentration of GFP was 18µg/mL.

The system was composed by 2% w/w TX with and without $MgSO_4$ or $(NH4)_2SO_4$. The phase diagram of the TX in buffer was obtained by the cloud-point method. Buffered solutions of the 2%TX with or without electrolytes, each with a total volume of 3 mL, were prepared in graduated 10-mL test tubes. Each solution was placed in a thermo-regulated device set at a

temperature of 36.2ºC for 2h to attain partitioning equilibrium. After 2h the two coexisting micellar phases formed were withdrawn separately and the biomolecules concentration was determined in each micellar phase. Nisin activity was determined by agar diffusion with *Lactobacillus sakei* as bioindicator. GFP concentration was determined by fluorimetry.

3 Results

Since it is often observed that the phase behavior of aqueous micellar solutions can be sensitive to the presence of electrolytes and impurities (Balzer and Lüders, 2000), it was first necessary to study how the TX/buffer phase diagram, that is, the temperature versus TX concentration coexistence curve, changes in the presence of these components. The phase diagram of the TX/buffer system in the presence of the different electrolytes was therefore mapped, and the results are presented in Figure 1. The experimentally measured coexistence curve, in the absence of any extra components, was and is also presented for comparison purposes.

As can be seen, the coexistence curves in the presence of the electrolytes have considerably shifted when compared to the TX/buffer curve in the absence of salts.

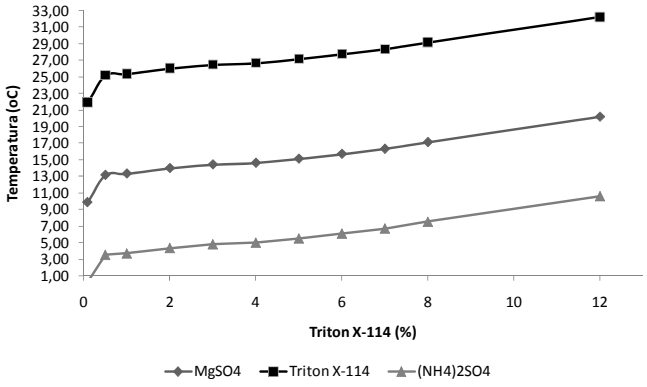

Figure 1. Phase diagram of Triton X-114/buffer system in the absence and in the presence of eletroctrolytes. The squares (■) represent the addition of $MgSO_4$; the losangles (♦) represents the coexistence curve for TX/buffer and the triangles (▲) represent the addition of $(NH_4)_2SO_4$.

The addition of salts in an ATPMS promotes a stronger electrostatic interaction between the water molecules compared to the hydrogen bonds between the head and the tail of the surfactant monomers. This phenomenon drives the water molecules to solvate the ions from the salts and the amphiphilic molecules interact more intensely, if compared to the absence of electrolytes (Carale, 1993).

The ions, such as sulphate, phosphate and chlorine, can increase the water structure and stabilize the structure of proteins, in this case they are called cosmotropic ions. On the other hand, there are some ions (perchlorite, thiocyanate, i.e.) which decrease the structure of the water and destabilizing the structure of proteins, being called chaotropic. The micelle formation is also changed by the presence of salts, once the critical micellar concentration (CMC) and the aggregation number (number of monomers in each micelle) are dependent on the solvation of ions (Anacker, Ghose, 1963; Tonova, Lazarova, 2005), also, the binding of the ions to the micelles affects the the organization and the electrostatic interaction between the polar heads and the tails of the surfactant monomers (Quina, Chaimovich, 1979; Brochsztain et al., 1990).

After the determination of the coexistence curves, systems containing nisin or GFP in the presence and in the absence of electrolytes were prepared and placed in a transparent thermo-regulated device whose temperature was controlled to within 0.02^{o}C.

In initial partitions, nisin was driven to the micelle-rich phase in the TX/buffer system, in the presence of the electrolytes similar behavior was observed, but the presence of $MgSO_4$ enhanced the most the partition of nisin to the micelle-rich phase (Figure 2). Results indicated that nisin partitions preferentially to the micelle rich-phase, with significant antimicrobial activity increase (up to 10-fold).

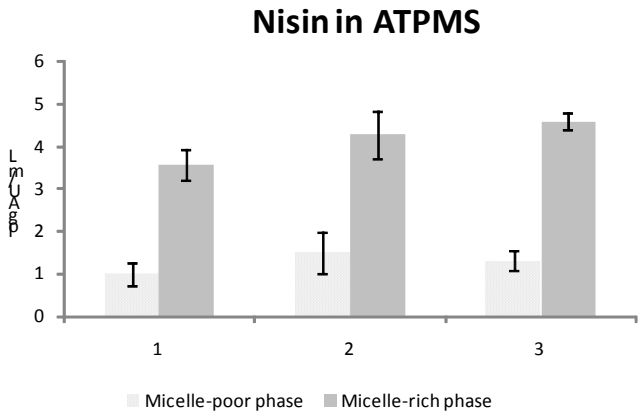

Figure 2. Nisin activity in the micelle-poor phase (gray and white bars) and in the micelle-rich phase (solid gay bars), after partitioning in ATPMS. (1) TX/buffer system; (2) TX/buffer and $(NH_4)_2SO_4$; (3) TX/buffer and $MgSO_4$. The error bars represent 95% confidence limits for the measurements.

The green fluorescent protein, in the TX/buffer system partitioned evenly between the phases, while in the presence of both salts GFP partitioned extremely to the micelle-poor phase (Figure 3).

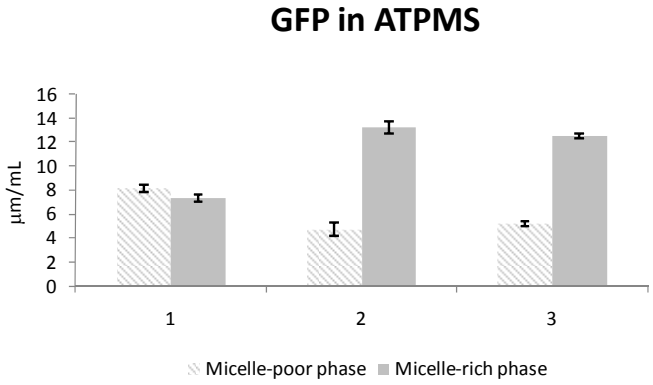

Figure 3. Green fluorescent proteins concentration in the micelle-poor phase (gray and white bars) and in the micelle-rich phase (solid gay bars), after partitioning in ATPMS. (1) TX/buffer system; (2) TX/buffer and $(NH_4)_2SO_4$; (3) TX/buffer and $MgSO_4$. The error bars represent 95% confidence limits for the measurements.

Different proteins are not soluble in water, but their solubility increases in the presence of electrolytes reaching a limit that can vary according to the protein and the chosen salt, this is called salting-in and can be explained by the interaction of the ions (positive and negative) in

the solution with the charged sites on the protein molecule, softening the interaction amongst them. For this reason, the electrostatic effect provided by diluted solutions containing salts is an important factor to the increase of solubility of proteins.

When the salt concentration is increased, some of the water molecules are attracted by the salt ions, decreasing the number of water molecules available to interact with the proteins. As a result of the increased demand for solvent molecules, the protein-protein interactions are stronger than the solvent-solute interactions; the protein molecules coagulate by forming hydrophobic interactions with each other. This process is known as salting out, and is caused by the presence of di or trivalent ions ($(NH_4)_2SO_4$, Na_2SO_4, i.e.)

The addition of salt, even milimolar concentrations, influences the partitioning of charged molecules. Although the ions partitions quite evenly between the phases, the small difference in their behavior in the phases creates a dielectrical potential that affects the biomolecules partition (SARUBBO et al., 2000). The addition of salts in ATPMS containing Triton X-114 influences the partitioning of both nisin and GFP, being a good strategy for extracting and purification of these biomolecules from the fermentation broth where they are biosynthesized.

The successful implementation of protein partitioning from a mixture containing the target biomolecule and other compounds, in a two-phase aqueous micellar system, presented in this work, represents an important step towards developing a novel separation method for proteins of interest.

4 Conclusions

The partitioning behavior of the biomolecules, nisin and GFP, in aqueous two-phase micellar systems in presence of electrolytes was investigated experimentally, showing that the target biomolecules can be extracted from respective media, either commercially available or produced by our research group. Increasing in activity of nisin and GFP concentration, after partitioning encourages further researches aiming to optimize the biomolecules extraction using simple tools as temperature variations, amongst others. In conclusion, the successful implementation of proteins partitioning, directly from a suspension containing the biomolecules and other unknown compounds, in a aqueous two-phase micellar system, presented in research, represents an important step towards developing a cost-effective separation method, and more generally, for other biomolecules of interest.

Topic: Integration of life sciences & engineering

Abstract

This work reports on the optimization of a recombinant *Pseudomonas aeruginosa* amidase (E.C.3.5.1.4) production in an *Escherichia coli* strain. The effect of several parameters such as temperature incubation, IPTG induction and ethanol shock on the enzyme aggregation *in vivo* was investigated. The results have demonstrated the formation of inclusion bodies at all the experimental conditions with the highest yield of soluble amidase relatively to other proteins obtained for the condition at 37ºC using 0.40 mM IPTG to induce growth with ethanol. Our findings showed that the addition of ethanol in LB ampicillin culture medium at 25ºC allowed the production of high levels of amidase but which aggregated quantitatively in a biological active form and exhibited a four-fold higher specific activity when compared with the soluble form of the enzyme. Nondenaturing solubilization of the aggregated amidase was achieved using L-arginine with the highest yield of enzyme solubilization obtained when using a concentration of 2 M. Conversely GdnHCl did not succeed in the denaturing solubilization of amidase inclusion bodies.

1- Introduction

The bacteria *Escherichia coli* is often the first choice of host in recombinant DNA technology for reasons of speed and simplicity (Middelberg, 2002) however a disadvantage is the formation of inclusion bodies when protein is overexpressed. High levels of expression of recombinant proteins often result in aggregation and accumulation in inclusion bodies which prevents the production of soluble protein at high yields.

Inclusion bodies are dense aggregates of misfolded polypeptide formed intracellularly due to the protein aggregation characteristics or possibly the inability for the cell processes to ensure that the expressed protein is correctly folded and soluble (Lilie *et a*l, 1998). Though the formation of inclusion bodies could facilitate protein purification refolding into biological active forms often is a complicated procedure which results in poor recovery being the major cost in production of recombinant proteins (Thomas and Baneyx, 1997).

Thus, it is desirable to avoid or at least reduce inclusion body formation producing the recombinant proteins in a soluble form *in vivo* and to purify the active polypeptide chains by conventional techniques.

There have been numerous reports on inclusion bodies and considerable research has addressed the mechanisms by which cells avoid forming aggregates of certain protein. The reduction of the cultivation temperature is known to increase the amount of soluble protein due to a decrease in the rate of protein biosynthesis. Another possibility of increasing soluble protein is to limit the induction of gene expression by the promoters which can be controlled by the inducer concentration such as isopropylthio-β-D-galactoside (IPTG) (Garcia-Junceda *et al*, 1995). Moreover, have also reported that supplementation of the grown medium with 3% ethanol can improve the solubility of some recombinant proteins (Thomas and Baneyx 1997).

Here we report the optimized production of a recombinant *Pseudomonas aeruginosa* amidase (E.C. 3.5.1.4.) overproduced in an *E coli* strain. In this study we inspect the combination of parameters such as cultivation temperature of LB ampicillin supplemented medium, IPTG concentration and ethanol shock in the prevention of the *in vivo* aggregation of this protein. However, repeatedly the literature reports on proteins aggregated in inclusion bodies which retain their biological activity and for such cases mild solubilization has proved to be the key for high recovery of bioactive protein from inclusion bodies in comparison to solubilization using a high concentration of a chaotropic agent (Tsumoto *et al*, 2003 Lilie *et al*, 2005). The present work also reports on the attempt to renaturate biologically active amidase inclusion bodies under nondenaturing conditions, using L-arginine, and strongly denaturing conditions, with guanidine hydrochloride (GdnHCl).

2- Materials and Methods

Culture Conditions

Recombinant *E.coli* JM 109 cells containing cloned amidase gene from wild-type strain 8602 of *Pseudomonas aeruginosa* amidase gene (Pacheco *et al*, 2000) were grown in Luria-Bertani (LB) medium, with 100 µg/ml ampicillin (Sigma Aldrich) at 37ºC or 25ºC, suplemented or not with 3% (v/v) ethanol and using different IPTG (Sigma Aldrich) concentrations for induction, ranging from 0.1 mM to 1mM.

Soluble and Insoluble cell fraction preparation

Cells grown at the different conditions mentioned above were collected by centrifugation, washed, and frozen when the absorbance of the culture at 600 nm was approximately 1 or higher (stationary phase). Frozen cells (15 mg) of each condition were suspended in 1 ml of 10 mM sodium phosphate buffer as pH 7.2 and broken by sonication with 3 bursts of 5 seconds at 150W. Part of this suspension (0.5 ml) which represents total cell extract (T) was collected and the remaining was centrifuged during 30 min at 13400 rpm at 4ºC in order to separate soluble (S) and insoluble (IS) cell fractions. Total cell, soluble and insoluble fractions for each of the tested conditions were assayed for amidase activity and protein concentration and analysed by electrophoresis.

Enzyme activity assay

Amidase transferase activity was determined using a modification of the method developed by Brammar and Clarke (Brammar and Clarke, 1964) using a solution of $FeCl_3$ 6% (w/v) in HCl 2%(w/v). The amidase activity was followed by measuring the formation of acetohydroxamic acid, using acetamide and hydroxylamine as substrates. The synthesis of acetohydroxamic acid was detected by formation of a brown colour complex, which absorbs at 490 nm (ε=0.026 $mM^{-1}.cm^{-1}$), when adding to the reaction mixture two volumes of $FeCl_3$ 6% (w/v) in HCl 2%(w/v) solution at several time intervals during the reaction.

A unit of enzymatic activity (UI) is defined as the amount of enzyme required to form 1 µmol acid acetohydroxamic per minute under the conditions of the reaction.

Protein assay and Electrophoretic analysis

Protein concentration was determined by Coomassie blue dye binding method using bovine serum albumin as the protein standard (Bradford, 1976).

Native polyacrylamide gel electrophoresis (PAGE) and SDS-PAGE with 8M Urea of T, S and IS cell fractions for all the tested conditions were carried out as described elsewhere and stained with silver staining (Hames, 1981). A method was also developed for the *in situ* detection of enzyme activity in native gels based on the amidase transferase activity. S and IS cell fractions containing amidase were subjected to 7.5 % native PAGE.

Subsequently the gel was cut in two, so that each half contained one of the samples of each cell fractions. Amidase transferase activity was detected by incubating at 25 ºC for 15 minutes one half of the gel with a reaction mixture containing equal amounts of 400 mM acetamide and 2 M hydroxylamine pH 7.0 in Tris-HCl buffer 75 mM at pH 7. Afterwards the formation of hydroxamic acid upon amidase reaction *in situ* was detected by overlaying filter paper soaked in a solution of $FeCl_3$ 6% (w/v) in HCl 2% (w/v) solution.

Brown bands indicated the position of the enzyme in the native gel relatively to the same position of the bands in the other half of the gel which was subjected to silver staining.

Solubilization of protein in inclusion bodies

In order to evaluate the capacity of L-arginine and guanidine hydrochloride (GdnHCl) in the successful solubilization of amidase aggregates obtained at the different tested conditions, IS cell fractions were suspended in L-arginine solutions and GdnHCl solutions at different concentrations, ranging from 0 to 1.5M of L-arginine and 0 to 3M GdnHCl. The mixture was incubated at room temperature with orbital shaking for 24 hours. After such period the sample was extensively washed with 10 mM sodium phosphate buffer as pH 7.2 in order to eliminate residues of solubilizing agent and centrifuged at 13400 rpm during 30 min at 4ºC separating S from IS solubilized fraction. The collected fractions were assayed for amidase transferase activity and protein concentration.

3- Results and Discussion

In order to determine the influence of parameters such as growth temperature, IPTG concentration and alcohol shock with ethanol in the beneficial production of native amidase, recombinant *E.coli* JM 109 cells containing the wild-type amidase gene from *P.aeruginosa* were grown at 37ºC or 25ºC in LB medium supplemented or not with 3% ethanol. The synthesis of the enzyme was also induced by addition of different concentrations of IPTG to the culture during the middle exponential phase. Culture cells harvested at stationary phase were disrupted into S and IS cell fractions as described. Figure 1 summarizes the results in enzyme yield for the effect of the different growth conditions to which the strain was subjected. It was evident that the cultures submitted to suboptimal growth condition, 25ºC, demonstrated an increased expression levels of recombinant amidase as referred in the literature (Thomas and Baneyx, 1997) except for 0.7 M IPTG. Moreover as expected this situation was verified in general also for conditions with ethanol shock as higher amidase specific activity was obtained in ethanol presence. The highest amidase specific activity was obtained for the S fraction of cells grown at 37ºC in ethanol presence with 0.40 mM IPTG induction. Cells grown in ethanol presence produce the maximum yield of soluble and insoluble amidase specific activity. The higher specific activity was found in the inclusion bodies obtained at 25ºC with ethanol. These results clearly demonstrate that all the conditions produce biologically active inclusion bodies.

Figure 2 shows the SDS-PAGE analysis of the produced proteins in T,S and IS cell fractions of the cultures induced with 0.7 mM IPTG subjected to different growth conditions as

representative of identical profile obtained when other IPTG concentrations were used. The insoluble fractions at 25ºC always showed the presence of amidase as the main component of all the protein which accumulated in the cell in the form of inclusion bodies (Lane 2 and 5) as opposed to the conditions at 37ºC in which others proteins expressed by the strain also aggregated (Lanes 9 and 12). The presence of a single protein band in IS fractions for all the tested conditions at 25ºC indicates homogenous inclusion bodies mainly constituted of amidase which offers the possibility of a facilitated recovery when compared with the inclusion bodies obtained 37ºC. The presence of amidase subunits was identified through its molecular weight, approximately 36 000Da, corresponding to the arrow shown at Figure 2.

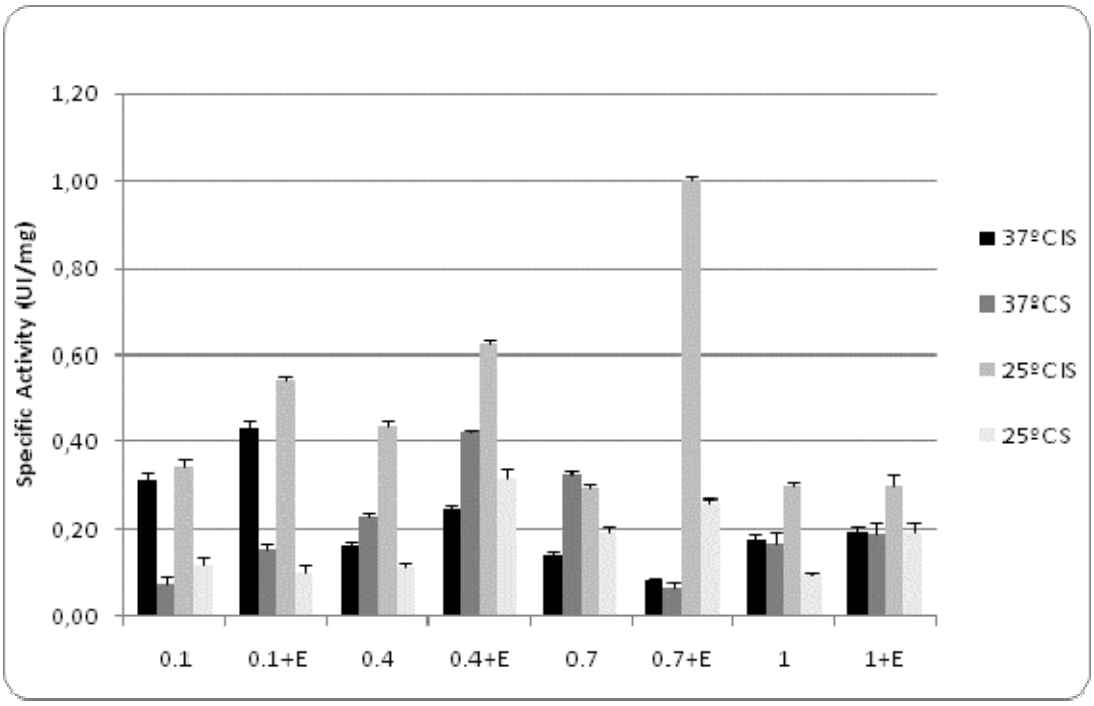

Figure 1- Effect of temperature, IPTG concentration and 3% ethanol supplementation (+E) on specific activity for amidase obtained in the soluble (S) and insoluble (IS) of cells submitted to different conditions.

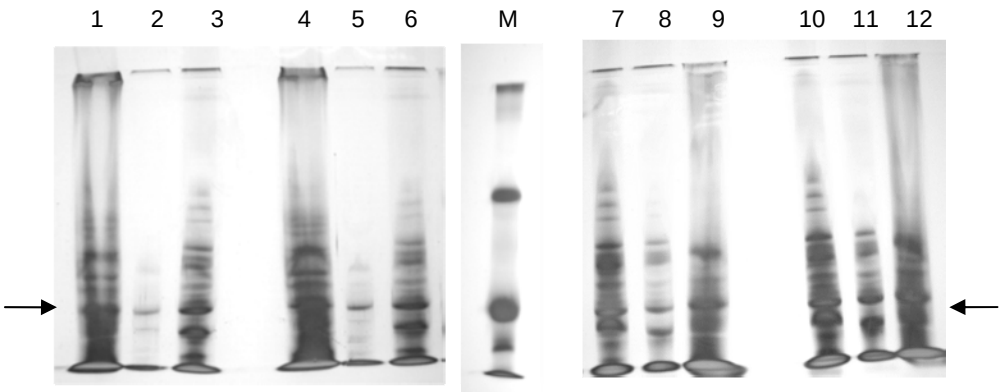

Figure 2- SDS-PAGE with urea analysis of amidase produced from *E.coli* recombinant strain under different growth condition in LB ampicilin medium using 0.7 mM IPTG. **Lanes: 1-** 25ºC+ 3% ethanol, total cell extract; **2-** 25ºC+ 3% ethanol, insoluble fraction; **3-** 25ºC+ 3% ethanol, soluble fraction; **4-** 25ºC, total cell extract; **5-** 25ºC, insoluble fraction; **6-** 25ºC, soluble fraction; **7-** 37ºC+ 3% ethanol, total cell extract; **8-** 37ºC+ 3% ethanol, soluble fraction; **9-** 37ºC+ 3% ethanol, insoluble fraction; **10-** 37ºC, total cell extract; **11-** 37ºC, soluble fraction; **12-** 37ºC, insoluble fraction; **M-** Molecular weight markers: 66000, 45000 and 24500 from top to bottom. The position of amidase subnunits is indicated by arrows.

In order to confirm the electrophoretic profile of the samples and the amidase activity of the cell fractions obtained for each condition, amidase transferase activity was performed *in situ* in a native PAGE as can be seen in Figure 3. The development of a brown colour in the gel lanes is indicative of the enzyme expression and the intensity of the formed colour is proportional to the quantity of expressed enzyme. The dark brown obtained in lanes 13-16 for 25ºC demonstrate an overall higher amidase activity when compared with 37ºC (lanes 1-4) as expected. Again the highest amidase specific activity was obtained for 25ºC with ethanol induced with 0.7 mM IPTG (lane 16).

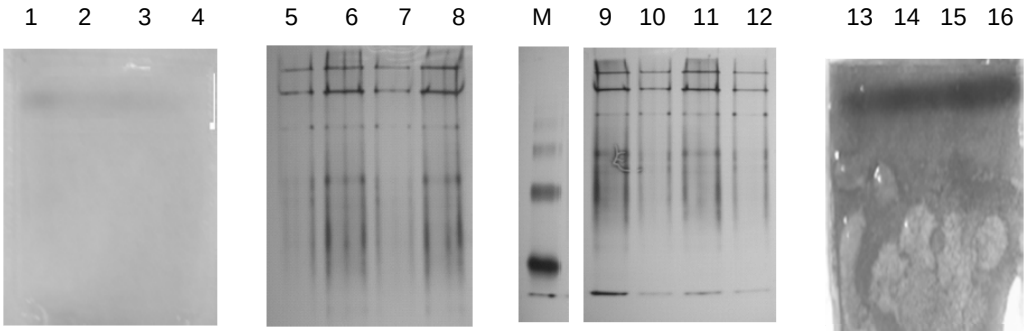

Figure 3 – Native PAGE analysis of amidase produced from *E.coli* recombinant strain under different growth condition in LB ampicilin medium using 0.7 mM IPTG. **Lanes: 1, 5 -** 37ºC, soluble fraction; **2, 6-** 37ºC, insoluble fraction; **3, 7-** 37ºC + 3% ethanol, soluble fraction; **4, 8-** 37ºC + 3% ethanol, insoluble fraction; **9, 13-** 25ºC, soluble fraction; **10, 14-** 25ºC, insoluble fraction; **11, 15-** 25ºC + 3% ethanol, soluble fraction; **12, 16-** 25ºC + 3% ethanol, insoluble fraction; **M-** Molecular weight markers: 132000, 66000, 45000 and 17800 from top to bottom.

The IS cell fractions obtained for each condition were subjected to solubilization using L-arginine solutions or guanidine hydrochloride at different concentrations. Addition of 0.25, 0.5 and 1 M L-arginine demonstrated a high increase in amidase yield in its bioactive and soluble form with the best results achieved when using 1 M L-arginine. When considering L-arginine concentration of 1.25 and 1.5 M the results are not as promising probably due to high concentration of L-arginine resulting in enzyme inactivation. The recovery of soluble protein was higher for the condition at 37ºC with 0.7mM IPTG and ethanol, with a recuperation of approximately 400 fold of amidase specific activity in the soluble fraction subjected to solubilization with L-arginine.

As opposed to the results obtained with L-arginine there was no amidase specific activity in S solubilized fractions obtained after solubilization with guanidine hydrochloride possibly due to the denaturing properties of guanidine hydrochloride and the incapacity for the enzyme to renaturate and restore its activity.

Nevertheless, a smaller increase (approximately 75 fold) in amidase activity for S solubilized fractions in the absence of L-arginine and guanidine hydrochloride (0 M) was verified in general for all conditions which suggest the importance of agitation in the solubilization of aggregated enzyme.

The effect of L-arginine is often attributed to the ability of arginine to suppress aggregation of proteins in which aggregates formed have native-like conformation probably showing biological activity (Tsumoto *et al*, 2003 Lilie *et al*, 2005). Our results seem to be consistent with such assumption however Fourier Transform Infrared Spectroscopy (FTIR) can be used in order to evaluate the secondary structure of the aggregates obtained and the effect of the used solubilization agents.

4 - Conclusions

Results have shown that all of growth conditions tested produced amidase aggregated in the form of inclusion bodies with the conditions at 25ºC showing inclusion bodies constituted by amidase as the single protein. For the overall of the tested conditions higher specific activity of soluble amidase was obtained at 37ºC in the presence of 3% ethanol. Nevertheless the highest specific activity was found at the inclusion bodies when the cells were grown at 25ºC in the presence of ethanol using 0.7mM IPTG for induction.

A method was developed in order to solubilize the aggregated amidase obtained in all the tested conditions using L-arginine as a non denaturing agent as opposed to GdnHCl that should be avoided. The efficiency of L-arginine in the non denaturing solubilization of amidase from inclusion bodies is being evaluated in a consistent FTIR analysis of aggregates structure which is already in progress.

Topic: Integration of life sciences & engineering

Abstract

In this work, three competing unstructured mathematical models for the biomass growth by recombinant *E. coli* strains with different acetate inhibition kinetics terms were evaluated for batch processes at constant temperature and pH.
The models considered the dynamics of biomass growth, acetate accumulation, substrate consumption, Green Fluorescence Protein (GFP) production and three metabolic pathways for *E. coli*. Parameter estimation and model validation was carried out using the Systems Biology toolbox for Matlab (The Mathworks) with different initial glucose concentrations (5g/kg to 25g/kg) in a 5dm^3 bioreactor. Model discrimination was based on the two model selection criterion (Akaike's information criterion and normalized quadratic difference between the simulated and experimental data criterion). The first model described by Jerusalimsky approach is an approximation to the non-competitive substrate inhibition. Cockshott approach describes the inhibition at high acetate levels and Levenspiel considers the critical inhibitory acetate concentration that limits growth. Within the studied experimental range, Jerusalimsky model provided a good approximation between real and simulated values and should be favored. The model describes the experimental data satisfactorily well.

1 Introduction

Acetate, when present in *Escherichia coli* fermentations during aerobic growth on glucose is a major obstacle to cell growth and recombinant protein production (Jensen and Carlsen 1990,Nakano *et al.* 1997) and a detailed documentation of acetate production becomes important.
Many different mathematical models were reported in the literature to describe the kinetics of primary metabolites and the acetate overflow metabolism from *E. coli* (Varma and Palsson 1994,Xu *et al.* 1999, Akesson *et al.* 1999). However, there have been few studies focused on the recombinant proteins (GFP) production multi-route models with acetate inhibition kinetics. Lee and Ramirez (1992) used a simple and unstructured model to simulate recombinant protein production that include inducer effect on cell growth and recombinant protein production. A similar model was used by Chae and co-workers (2000) with introduction product inhibition term on the specific growth rate. However, models from previous works for recombinant proteins production are based usually on simplified Monod kinetics description and have neglected the influence of inhibition effect of acetate on *E. coli* growth and glucose uptake although it is known that this play an important role.
The models evaluated here take into account three specific substrate uptakes kinetics with different acetate inhibition terms for the representation of the growth of recombinant *E. coli* strain HMS174AcGFP1. In this work, a set of batch data on fermentations of glucose has been also collected for a better understanding of the environmental effects (glucose concentration) of the acetate overflow phenomenon and

GFP production. The aim of this study was to test three well-established kinetic models for their suitability to describe recombinant *E. coli* growth using batch fermentations data. Subsequently, the best kinetic model can be applied to fed-batch processes in order to determine optimal operation conditions.

2 Material and Methods

Pre-cultures and batch cultures
E. coli HMS174(DE3)pet28aAcGFP1 strains were obtained originally from the stock centre and were used throughout the present study. In these strains, GFP proteins are induced by isopropyl-β-D-thiogalactopyranoside (IPTG). Cells from a glycerol stock culture stored at -80ºC were reactivated by inoculating a frozen aliquot (1ml) into 1L Erlenmeyer flasks with 300 ml of a defined inoculum media with kanamicin (0.03 g kg^{-1}). Flasks were then incubated at 37ºC and 150 rpm until the culture reached exponential phase. Finally, the culture was then transferred into the reactor, containing 3 L from defined medium as described previously in Rocha and Ferreira (2002) to give an initial optical density at 600nm (OD_{600}) in the bioreactor of 0.20-0.25.

Medium and Fermentation Conditions
Cells were grown in a defined medium, with kanamicin and ampicilin as described above. The different initial glucose solution (5.0, 10.0, and 25.0 g kg^{-1}) and the mineral solution were sterilized separately by autoclaving and were later added to the reactor together with a sterile filtered solution containing $MgSO_4$, $CaCl_2$, trace elements, vitamins and thiamine prior to inoculation.
All fermentations were carried out in batch-mode in a 5 L fermenter from B. Braun Biotech (Germany) with a working volume of 3 L equipped with a digital control unit (DCU). In addition, temperature, pH, dissolved O_2 and CO_2 sensors were connected to this DCU and to a data acquisition system. All the cultures were run at ca. 25h and with controlled temperature (at 37ºC) and dissolved oxygen (above 30% to maintain aerobic condition of growth at all times). Silicone (Merck) was used as antifoam reagent.

Analytic Methods
Cell growth was monitored by measuring the OD at 600nm on a UV-visible Jasco V-560 spectrophotometer. The OD_{600} unit was converted to the cell dry weight based on the relation: OD_{600} = 0.21 g kg^{-1}. Samples for acetate and the glucose measurements during the course of the batch fermentations were collected at regular intervals and centrifuged at 10000g in a microcentrifuge for 10 min. After filtration through a 0.2 mm syringe filter the samples were stored at -20ºC for subsequent analysis. Glucose and acetate concentration in samples were detected and measured by high performance liquid chromatography (HPLC) with a Metacarb 87H, 300x7.8mm column (Varian, Palo Alto, CA), a UV detector (Jasco) with a detection wavelength of 210 nm and a refractive index detector (Knauer). The mobile phase used was 0.01N H_2SO_4 with a flow rate of 0.7ml min^{-1} and at a column temperature of 60ºC. The glucose concentration was also measured using commercial enzymatic kits according to the manufacturer's instructions (Spinreact, Sant Esteve de Bas, Spain).

Kinetic Model Development
The presented model combines terms for cell growth, substrate consumption, acetate accumulation and green fluorescence protein (GFP) production for fed-batch cultures with constant pH and temperature. Glucose was assumed to be the only carbon source used for the oxidation and fermentation processes needed for biomass growth and GFP production (eq. 1 and 2). The oxidation of acetate is considered as well (eq. 3) but the oxygen and carbon dioxide dynamic are not. The potential effect of the induction with isopropyl-beta-Dthiogalactopyranoside (IPTG) on the decrease of the growth rate

and yield coefficients was not contemplated in the model. The substrate inhibition was also not considered in the kinetic model.

The reformulated model was based from Bastin and Dochain (1990) and considers three main metabolic pathways:

Oxidation of glucose,

$$k_1 S \xrightarrow{\mu_1} X + k_5 P \qquad \text{if } qs < qs_{cr} \text{ and } A > 0 \qquad (1)$$

fermentation of glucose,

$$k_2 S \xrightarrow{\mu_2} X + k_3 A \qquad \text{if } qs < qs_{cr} \text{ and } A \leq 0 \qquad (2)$$

oxidation of acetate,

$$k_4 A \xrightarrow{\mu_3} X \qquad \text{if } qs > qs_{cr} \text{ and } A > 0 \qquad (3)$$

and the following four ordinary differential equations (4-6), capable of describing glucose fermentation by *E. coli*:

The biomass growth is given by,

$$\frac{dX}{dt} = (\mu_1 + \mu_2 + \mu_3)X - \left(\frac{F}{W}\right)X \qquad (4)$$

and the substrate concentration by,

$$\frac{dS}{dt} = (-\mu_1 k_1 - \mu_2 k_2 - m_S)X - \frac{((\mu_1 + \mu_2 + \mu_3)k_5 + \beta)X}{K_6} - \left(\frac{F}{W}\right)(S_0 - S) \qquad (5)$$

that included the substrate conversion to product formation, maintenance and cell growth.

Finally, the acetate accumulation and product formation is described by equations 6 and 7 respectively,

$$\frac{dA}{dt} = (\mu_2 k_3 - \mu_3 k_4)X - \left(\frac{F}{W}\right)A \qquad (6)$$

$$\frac{dP}{dt} = (\mu_1 + \mu_2 + \mu_3)k_5 X + \beta X - \left(\frac{F}{W}\right)P \qquad (7)$$

where P (GFP production) includes a growth and non-growth associated term. The variable X, S, A and P represents biomass, substrate, acetate and product concentrations, respectively (g kg^{-1} and mg kg^{-1} for product); F and W are the mass flow feed rate and weight of the fermentation broth, respectively (for cultures operated in batch mode F is zero; the k_i are the yield coefficients; β, non-growth associated product constant; m_s maintenance coefficient and μ_i the specific growth rates.

As described in the introduction, it is known that acetate accumulation limits the productivity of the fermentation process. For this reason, three alternative equations for the specific substrate uptake rates (q_s) with different acetate inhibition terms tested in this study at initial glucose concentration 5 g kg^{-1}. Model I, according to Jerusalimsky (Roels, 1983) is an approximation to the non-competitive substrate inhibition. Model II (Cockshott and Bogle 1999) describes the inhibition at high acetate levels and model III (Han and Levenspiel 1988) considers the critical inhibitory acetate concentration that limits growth.

3 Results and Discussion

Parameter estimation and model evaluation

The simulated data are obtained by solving the differential equations (1-4), and the experimental state variables were taken from the experimental studies described in the Materials and Methods section. The kinetic parameters were estimated by fitting the experimental data using the simulated annealing algorithm from the Systems Biology toolbox running in Matlab v.7.1.0 (The Mathworks). For model discrimination, Akaike's information criterion (AIC) and normalized quadratic difference between the simulated and experimental data criterion (*dif*) were used.

Batch fermentations using *E. coli* for HMS174pacGFP strain were performed for estimation and validation of model parameters. Observation of the experimental data revealed that acetate was not metabolized (Figure 1). In this way, the metabolic pathway for the acetate oxidation (μ_3) was not considered in the developed model. Initial estimates for the yield parameter (k_5) were first calculated using the experimental data obtained from the batch fermentations. The initial estimates for the remaining parameters were taken from the literature for *E. coli* on a single substrate. Subsequently, some of the parameters were set to the values described on Table 1 (k_1, k_2, K_s, m_s, β_1, n, and A_{crt}), while all the others parameters were fitted using the experimental data.

Table 1. Initial parameter values (kinetics and yield coefficients) for the growth of *E. coli* K12 taken from the literature and determined from experimental data.

Parameter	Values	Units	Reference (s)
k_1	1.88	($g_S\ g_X^{-1}$)	(Galvanauskas *et al.* 1998)
k_2	20	($g_S\ g_X^{-1}$)	(Rocha, 2003)
$\boldsymbol{k_3}$	14	($g_A\ g_X^{-1}$)	(Rocha, 2003)
k_4	-	($g_A\ g_X^{-1}$)	-
$\boldsymbol{k_5}$	9.22	($mg_P\ g_X^{-1}$)	determined
$\boldsymbol{k_6}$	50	($mg_P\ g_S^{-1}$)	(Aucoin *et al.* 2006a)
$\boldsymbol{qs_{max}}$	1.8	($g\ g^{-1}\ h^{-1}$)	(Galvanauskas *et al.* 1998)
K_s	0.1	($g\ kg^{-1}$)	(Galvanauskas *et al.* 1998)
$\boldsymbol{K_{ai}}$	15.5	($g\ kg^{-1}$)	(Galvanauskas *et al.* 1998)
$\boldsymbol{qs_{cr}}$	0.15	($g\ g^{-1}\ h^{-1}$)	(Akesson *et al.* 1999)
m_s	0.02	($g\ g^{-1}\ h^{-1}$)	(Galvanauskas *et al.* 1998)
β	0.1	($mg\ g^{-1}\ h^{-1}$)	(Aucoin *et al.* 2006b)
A_{crt}	0.9	($g\ kg^{-1}$)	(Aristidou *et al.* 1999)
n	1.41	-	(Théodore and Panda 1999)

The estimated parameters are showed in Table 2. The parameters obtained from the experimental data fitting were in relatively agreement to the values observed in the literature reports for model I, contrary to the model II and III. However, the value estimated from the parameter k_3 and qs_{cr} was higher in comparison to the literature data. This discrepancy might be attributed not only to different operating conditions and/or *E. coli* strains, but also to different modeling strategies to parameter fitting.

The proposed Jerusalimsky and Cockshott approaches (models I and II, respectively) describe very well the experimental data for the time courses of glucose, acetate, biomass growth and GFP concentration (Figure 1). However, the model III curves were in significant disagreement with the experimental data for the acetate concentration. These observations can be confirmed by comparing the statistical analysis from selection models criterions AIC and *dif*. According to the Table 2, models I has the lowest AIC and *dif* values. As a consequence, it was favoured and selected for further analysis.

Table 2. Estimated values of parameters for the model I obtained by fitting the experimental data with 5 g kg^{-1} initial glucose concentration.

Parameter	Model I	Model II	Model III
k_3	33.45	69.89	70.00
k_5	12.78	12.73	12.02
k_6	51.95	25.73	25.00
qs_{max}	0.97	0.89	7.50
K_{ai}	7.75	7.75	25.60
qs_{cr}	0.61	0.63	0.63

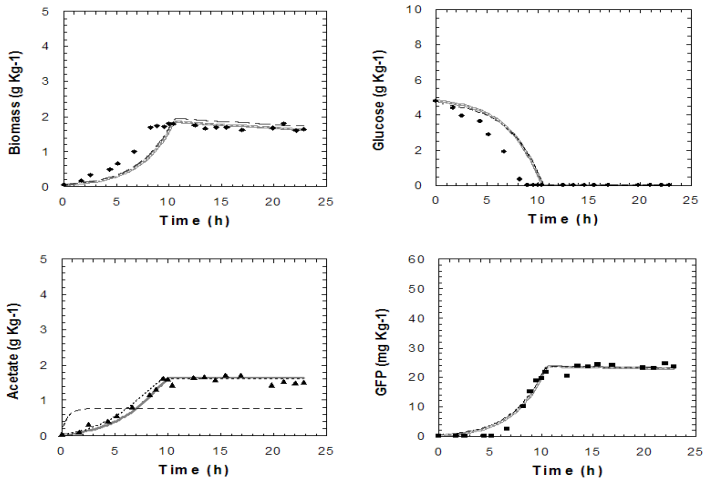

Figure 1. Comparison between experimental and simulated data (a) biomass growth, (b) glucose, (c) acetate and (d) GFP concentration in batch fermentation by HMS174AcGFP1 at 5g kg^{-1} initial glucose concentration. Solid lines represent the simulation data from model I, depicted lines the model II and dashed lines the model III, using the fitted parameters (Table 2). Lines from model I, II and III for glucose and GFP are overlapped for biomass, glucose and GFP concentrations.

Table 3. Model selection criterion Akaike's (AIC) and normalized quadratic difference between the simulated and experimental data (*dif*) at 5.0 g Kg^{-1} initial glucose concentration for model I, II and III.

Criterion	Model I	Model II	Model III
AIC	201.28	221.52	243.14
dif	2.32	2.34	3.45

* AIC and *dif* are the average values from the variable states

To validate the developed model it is necessary to use other experimental data set than that applied to identify initial parameters. Therefore, the selected kinetic model (model I) was validated and tested using the fitted parameters values with different fermentation conditions. Figure 2 compares the experimental data profiles and simulation data 10 g kg^{-1} concentration.

The better fitting with this initial glucose concentration to the experimental biomass, acetate and GFP concentration is observed and demonstrates the applicability of the presented kinetic model. However, the model was unable to predict the experimental data with 25.0 g kg^{-1} glucose concentration (data not shown). Additionally, the simulated glucose concentration at 10 g kg^{-1} glucose concentration was considerably lower than the one obtained by experimental methods, probably because there is a substrate consumption inhibition phenomenon that is not considered in the model.

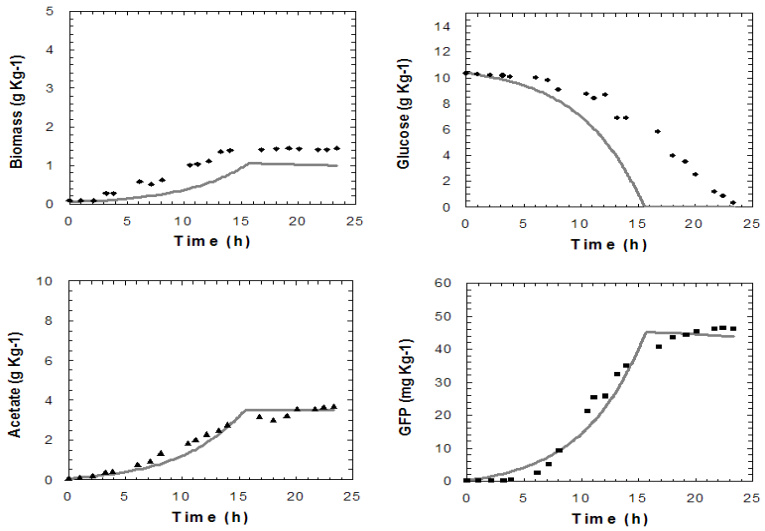

Figure 2 Comparison between experimental and simulated data (a) biomass growth, (b) glucose, (c) acetate and (d) GFP concentration in batch fermentation by HMS174AcGFP1 at 10g kg^{-1} initial glucose concentration.

4. Conclusions

A mathematical unstructured model describing the recombinant protein production (GFP) in *E. coli* HMS174AcGFP1 using acetate inhibition kinetics was developed for batch fermentations. The model considers the inhibition of recombinant cultures by acetate inhibition. Using this modelling approach a satisfactory prediction was achieved (5-10 g Kg^{-1}), with the parameter obtained by experimental data fitting. Within the range of the model, the Jerusalimsky and Cockshott approaches should be favoured.

Keywords: Protein-bound polysaccharides, *Coriolus versicolor*, submerged fermentation, edible mushrooms
Topic: Integration of life sciences & engineering

Abstract

Some mushroom strains are able to synthesize polysaccharopeptides with antitumoral and immunostimulating properties. The aim of this study was to define experimental conditions to optimize the production of protein-bound polysaccharides by *Coriolus versicolor*. In order to evaluate and to optimize the production of these compounds, submerse cultures were performed with four different carbon sources: glucose, maltose, sucrose and mannitol. Additionally, aiming for a clean process and to reduce the medium cost, two kinds of agro-industrial residues were used: tomato pomace and beet wastes.

The highest polysaccharide concentration was achieved with tomato pomace as agro-industrial residue corresponding to the 14th day of culture. Based on these results *C. versicolor* was cultivated in a basal medium plus tomato pomace in a stirred bioreactor. Endocellular and exocellular protein-bound polysaccharides were quantified. The concentration of the polysaccharide compounds was higher in the supernatant than in mycelia and supernatant complex has higher protein content. The main protein-bound polysaccharides produced by *C. versicolor* ranged between molecular weights of $1.3x10^3$-$8.9x10^4$ Da.

The comparison of the results obtained in this study with those reported in the literature, let us to confirm the interest of this selected culture medium with tomato pomace, in order to maximise the production of complexes protein-polysaccharides by *C. versicolor*. Besides, this clean process allows valuing the agro-industrial residues with a low cost and a higher production of polysaccharide compounds.

1. Introduction

Several species of mushrooms have been valued as edible and medicinal resources. Polysaccharides mushroom-derived have shown medicinal effects such as blood pressure and cholesterol lowering, liver protection, anti-fibrotic, anti-inflammatory, anti-diabetic and anti-viral activities. Additionally, some strains are able to synthesize new polysaccharopeptides with antitumoral and immunostimulating properties (Cui *et al*., 2007; Li *et al*., 2008). Protein-bound polysaccharides or polysaccharopeptides produced by the white rot fungus, *C. versicolor*, are effective immunopotentiators used to supplement the chemotherapy and radiotherapy of cancers and various infectious diseases (Cui and Chisti, 2003).

Polysaccharopeptide Krestin (PSK) and polysaccharopeptide PSP are the best known commercial polysaccharopeptide preparations obtained from *C. versicolor* mycelium (Cui and

* Corresponding author: Tel + 351-266745313. E-mail:atc@uevora.pt

Chisti, 2003). In fact, most of the reported studies referred polysaccharides isolated from mycelium (IPS), however few studies on exopolysaccharides (EPS) from *C. versicolor* have been reported (Kim *et al.,* 2002; Tavares *et al*., 2005). Really, polysaccharides represent the major constituent that establishes the rigidity and morphological properties of the fungal cell wall and, depending on the culture conditions, they can be excreted to the medium. In this work, endo and exo protein-bound polysaccharides produced by *C. versicolor* will be investigated in flasks and stirred-tank bioreactor cultures.

2. Material and Methods

Microorganism and inoculum

C. versicolor was isolated from *Quercus suber* and kindly provided by ISEL. The culture was maintained on PDA, transferred to a fresh agar plate every month, and grown at 28 °C for approximately 7 days. Mycelia of *C. versicolor* on the media surface were cut and transferred to culture flasks.

Cultures

Cultures were prepared in shake-flask with a basal media comprised by the following ingredients per liter: yeast extract 2 g, KH_2PO_4 0.8 g, $MgSO_4.7H_2O$ 0.5 g, $Na_2HPO_4.2H_2O$ 0.25 g, NH_4NO_3 1 g, pH 6.0. Four different carbon sources were provided at 10 g L^{-1} in the basal medium: glucose, maltose, sucrose and mannitol. Additionally two kinds of agro-industrial residues were used: tomato pomace and beet wastes. The different carbon sources were added one by one to the basal medium. Flasks were incubated at 28°C, for 20 days using an orbital shaker at 150 rpm. Samples were collected periodically along the twenty days of the assays.

Fermentations in the bioreactor were carried out in batch mode, using glucose or tomato pomace, at an agitation speed of 145 rpm and air flow rate of 2 vvm, for approximately 20 and 14 days respectively, at 28ºC. Sterilized water was added to the fermented broth to compensate the loss of moisture every 24 h and maintained at 1,3L fill level.

Biomass and Glucose concentration

The culture broth was filtered through Whatman nº 1 filter paper, washed with distilled water and the retained biomass was dried at 60 ºC for 48 h for the determination of the biomass dry weight. Glucose concentration in the supernatant of cultures was determined using an enzymatic Kit with glucose oxidase (D-Glucose, Roche)

Polysaccharide recovery

Isolation and quantification of extracellular and intracellular polysaccharides

EPS were isolated from supernatant of cultures, adding four volumes of 95% ethanol and kept at 4 °C for 12 h, centrifuged at 1350×g for 15 min at 4 °C. Precipitate was resuspended with equal volume of 75% ethanol and centrifuged again as described above. Polysaccharide precipitated were dried at 60 °C to remove residual ethanol and the residues were dissolved in an equal volume of distilled water (Lin and Sung, 2006).

The mycelial biomass pellets were heated in water (90ºC) for 2 h to release the IPS, filtered through Whatman filter paper and the extract was collected (Lee *et al*., 2006). The IPS in the extract was recovered using the same procedure as the EPS recovery.

The EPS and IPS concentration were determined by phenol–sulphuric method (Dubois *et al*., 1956) using glucose as a standard curve.

The polysaccharide protein contents were determined by Lowry method with bovine serum albumin as the standard (Lowry *et al*., 1951).

Polysaccharide molar mass

Weight-average molecular weights (Mw) of the polysaccharides were determined using size-exclusion chromatography (SEC) coupled to UV (280 nm) and RI detectors, using a HPLC system. Mobile phase, ultrapure water containing 0.05% NaCl, was pumped at a flow rate of

0.6 ml/min. Compounds detection was simultaneously performed on the UV and RI detector. Standards of polyethylene glycol (1.5, 3, 6 and 20 kDa, Sigma Chemical Co., MO, USA) were used for determination of biopolymers molecular weight.

3. Results and Discussion

Effect of carbon sources in cultures

Four different defined carbon sources were provided in the basal medium (glucose, maltose, sucrose and mannitol), to examine the effect of carbon sources on mycelial growth and exobiopolymer production. As shown in Table 1-A, high levels of mycelial biomass were obtained with sucrose or mannitol, whereas higher levels of EPS and IPS were obtained for sucrose and glucose as the sole carbon source. Additionally, intending for a clean process and to reduce the medium cost, two kinds of agro-industrial residues were used: tomato pomace and beet wastes. The biomass formed in cultures with agro-industrial residues was higher than cultures with defined carbon sources, mainly in beet wastes (Table 1-B).

Table 1 Effect of carbon sources on mycelial biomass, final pH, EPS and IPS production in shake flask cultures of *C. versicolor*[a]

	Mycelial biomass ($g.L^{-1}$)	EPS ($g.L^{-1}$)	IPS ($g.L^{-1}$)	Final pH
A				
Glucose	2,01 ± 0,02	$17,83x10^{-2} \pm 4,01x10^{-2}$	$2,03x10^{-2} \pm 0,76\ x10^{-4}$	6,84 ± 0,01
Sucrose	2,38 ± 0,02	$15,80x10^{-2} \pm 1,07x10^{-2}$	$1,05\ x10^{-2} \pm 2,46\ x10^{-4}$	6,44 ± 0,04
Maltose	1,62 ± 0,02	$7,49\ x10^{-2} \pm 1,80x10^{-2}$	$0,78\ x10^{-2} \pm 0,92\ x10^{-4}$	7,27 ± 0,04
Mannitol	2,53 ± 0,01	$8,38\ x10^{-2} \pm 2,84x10^{-2}$	$1,15\ x10^{-2} \pm 0,65\ x10^{-4}$	4,73 ± 0,02
B				
Beet wastes	6,45 ± 0,01	$18,30x10^{-2} \pm 2,45x10^{-2}$	$1,56\ x10^{-2} \pm 1,42\ x10^{-4}$	7,27 ± 0,01
Tomato pomace	4,82 ± 0,01	$55,05x10^{-2} \pm 3,40x10^{-2}$	$2,50\ x10^{-2} \pm 7,21\ x10^{-4}$	7,23 ± 0,02

[a]Fermentations were carried out for 20 days at 28ºC with initial pH 6. Values are mean of triple determination with standard deviation. A- Defined carbon sources. B- Agro-industrial residues used as carbon sources.

Maximal protein-bound polysaccharide (EPS) concentration obtained in batch cultures ranged between 0.15-0.90 $g.L^{-1}$ (Fig. 1) and IPS concentration, at the end of cultures, ranged between 0.01-0.03$g.L^{-1}$ (Table 1). The highest polysaccharide concentration was achieved with tomato pomace as agro-industrial residues corresponding to the 14^{th} day (Fig. 1).

Fig 2 shows some aspects of cultures performed with agro-industrial residues. The pellets formed in tomato pomace cultures were smaller than those formed in beet wastes cultures (Fig. 2-a,b). Mycelial morphology (Fig.2-c) illustrate the homogeny of pellets developed, however, their size and hairiness were different according to the substrate used. The gelatinous appearance of the pellets, in part due to the presence of exopolysaccharides adhered to the mycelia can led to an overestimation of the biomass and the underestimation of exopolysaccharides concentration (Gern *et al*., 2008).

C. versicolor was cultivated in a basal medium plus glucose in a stirred bioreactor aiming the optimization of EPS and IPS production. Fig. 3 shows the dynamic changes of glucose utilization, EPS production, dissolved O_2 (%) and pH during 20 days of culture. Dissolved oxygen (DO_2) concentration also fell rapidly during the exponential growth phase of fermentation (Fig. 3-b). This may be due to the rapid increase of biomass concentration observed in this period, simultaneously, a decrease of glucose was observed. pH value increased afterwards 10 days of culture, when glucose on the medium is residual. The yield of exobiopolymer formation from substrate ($Y_{P/S}$) was 0.0297 at the final of culture however the highest EPS concentration (0,445 g/L) was produced after 15 days. EPS concentration in bioreactor was increased around 1.5 times comparatively to flask cultures, on the same culture medium. The consumption of these polymers during the process was observed in our study and could be attributed to the existence of residual glucose in the culture medium,

starting from the 15th day of culture (Fig. 3), this phenomenon was observed in all cultures (Fig. 1, 3) and is also referred by other authors (Rosado *et al.*, 2002; Wisbeck *et al.*, 2005).

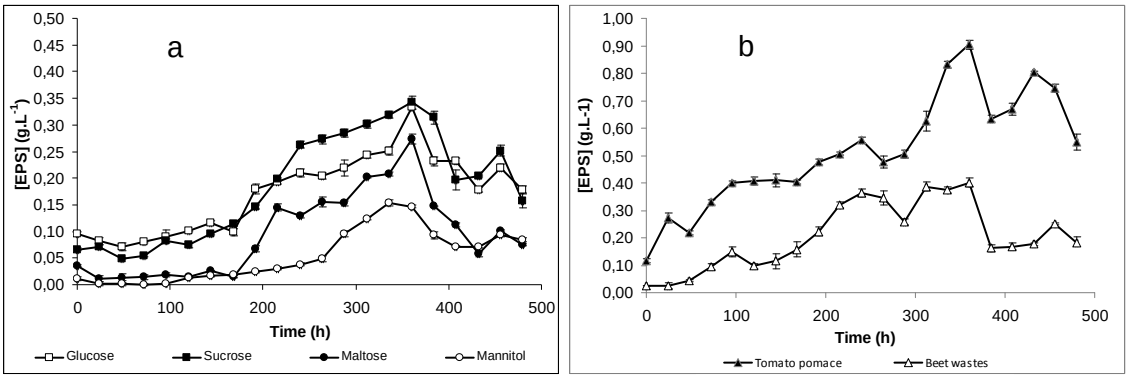

Figure 1- Dynamic changes of EPS production in shake flask *C. versicolor* cultures: a- Defined carbon sources. b- Agro-industrial residues.

Fig.2: Aspects of *Coriolus versicolor* cultures on tomato pomace (a) and beet wastes (b) Mycelial morphology observed with 6X enlargement (c)

Agitation could be benefit to the growth and performance of microorganisms, in fact agitation promote a better mixing of the fermentation broth, allowing to maintain a concentration gradient between the interior and the exterior of the cells and also favours oxygen supply. This is important for high biomass concentration, moreover, mycelial morphology can also be affected (Gern *et al*., 2008). In this work, a decrease in the size of the pellets was observed on stirred bioreactor, comparatively to flask cultures. Agitation and aeration cause probably damage to the stability of the pellets, affecting mycelial morphology.

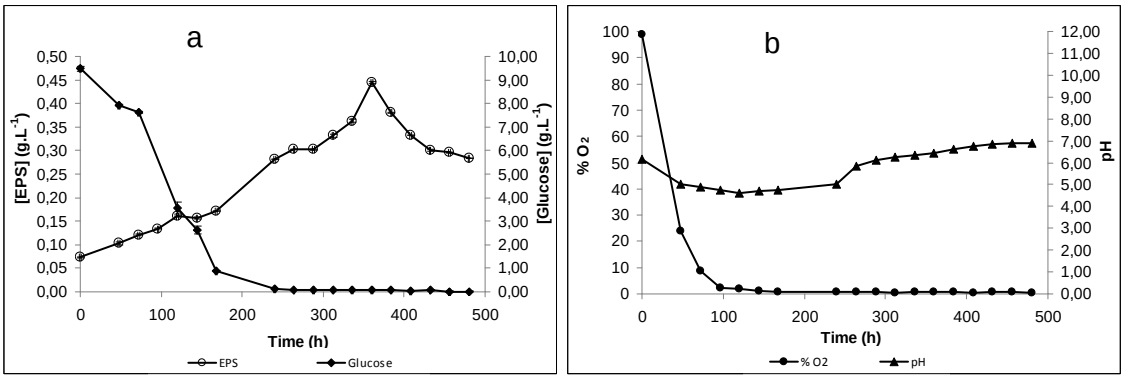

Figure 3- Dynamic changes of glucose utilization and EPS production (a), % O_2 dissolved and pH (b) during 20 days of *C. versicolor* culture, in bioreactor.

In order to enhance the production of protein-bound polysaccharides, *C. versicolor* was cultivated in a stirred bioreactor during 14 days, using tomato pomace. The EPS and IPS protein-bound polysaccharides were extracted, giving concentrations of about 1.7 $g.L^{-1}$ and 0.08 $g.L^{-1}$ respectively. This approach allows the increase of EPS production 1.9 times. The supernatant complex has a protein concentration 40 times higher than mycelia complexes, however the relationship polyssacharide/bounded proteins is two times higher in mycelium than in supernatant, revealing a different protein-bound polysaccharides production by *C. versicolor.*

Molecular weights of EPS and IPS

EPS and IPS produced in all cultures were separated by HPLC using a size exclusion column. Table 2 summarizes the molecular weights (Mw) of the main compounds isolated. The largest molecular weight fraction of EPS compounds (>10^4) were isolated in mannitol, maltose, tomato pomace and beet wastes, but the highest M_w EPS (>1,0x10^5 Da) was produced in maltose cultures. Molecular weight fraction of IPS was quite similar to the EPS produced for each carbon source, however, the highest M_w IPS (>1,0x10^5 Da) were produced in maltose, mannitol, tomato pomace and beet cultures. Nevertheless these IPS polymers were present in lower concentrations than EPS.

Table 2- Average molecular weights of EPS and IPS fraction separated by size exclusion chromatography

		Molecular weight (Da)			
		Peak 1	Peak 2	Peak 3	Peak 4
EPS	Tomato pomace	<1,0x10^3	1,3x10^3	2,9x10^3	1,7x10^4
	Beet waste	<1,0x10^3	3,5x10^3	9,8x10^3	8,9x10^4
	glucose	<1,0x10^3	1,3x10^3	2,9x10^3	
	sucrose	<1,0x10^3	1,4x10^3	3,5x10^3	7,6x10^3
	maltose	<1,0x10^3	3x10^3	3,5x10^3	>1,0x10^5
	mannitol	1,0x10^3	1,7x10^3	3,1x10^3	1,1x10^4
IPS	Tomato pomace	<1,0x10^3	5x10^3	>1,0x10^5	
	Beet wastes	<1,0x10^3	5x10^3	>1,0x10^5	
	glucose	1,3x10^3	5x10^3	9,0x10^3	2,6x10^4
	sucrose	1,3x10^3	1,2x10^4	2,6x10^4	
	maltose	<1,0x10^3	5x10^3	1,2x10^4	>1,0x10^5
	mannitol	1,3x10^3	5x10^3	1,2x10^4	>1,0x10^5

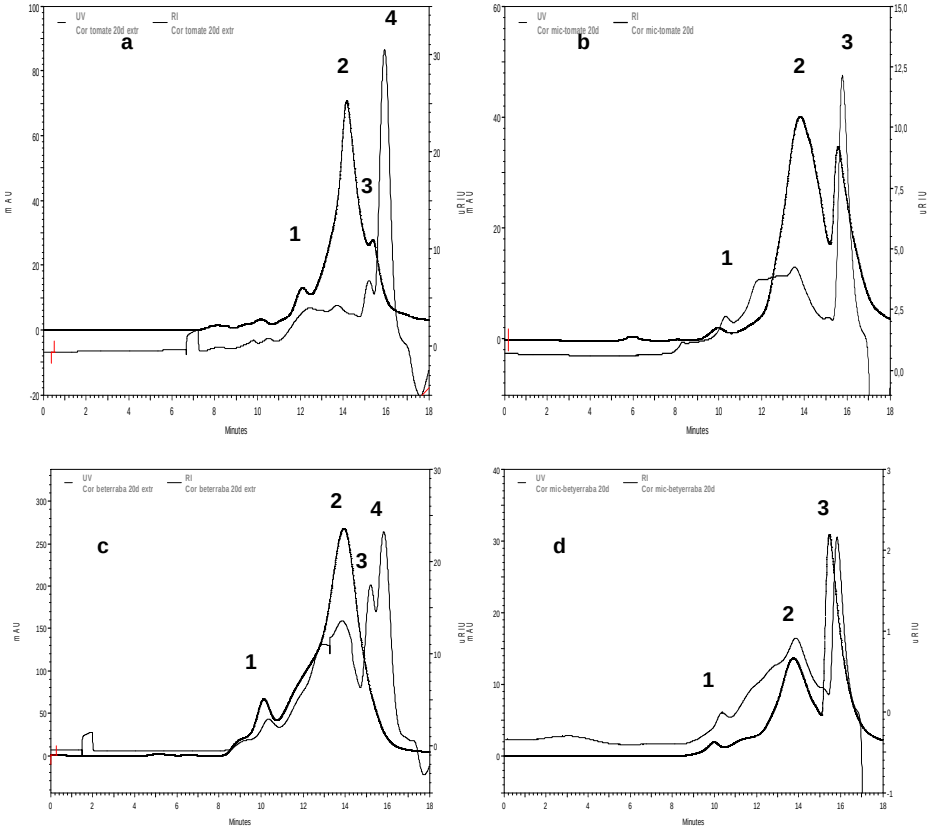

Figure 4- Chromatogram obtained from HPLC showing RI signal (line) and UV signal (dot) plotted as a function of retention time for *Coriolus versicolor* cultures using tomato pomace (a – supernatant; b – mycelium) or beet wastes (c – supernatant; d – mycelium)

Figure 4 shows chromatogram profiles obtained by HPLC with RI and UV signal for the EPS and IPS compounds produced by *C. versicolor* in tomato pomace or beet wastes cultures. IPS chromatograms of the two cultures had very close profile (Fig. 4 b, d), but it must be noted that very similar molar mass range does not imply similar molecular structure and molecular conformation. From EPS chromatograms it is evident that the largest molecular weight fraction was present at a very low concentration (< 3%) compared to the other molecular weight fractions (Fig. 4 a, c). In both cultures, peak 2 of EPS had a nearly molecular weight (~3 x10^3 Da).

Some authors related the production of EPS and IPS compounds by mushrooms. Sakagami *et al.* (1991) reported sub-fractions found in PSK whose the largest fraction is >2.0 x 10^5 Da. Wang *et al.* (1996) compared EPS with IPS using a gel permeation column and they found that IPS and EPS contained two high molecular weight fractions (2.8 x 10^4 Da from IPS; 1.5 x 10^4 Da from EPS) and a lower molecular fraction of ~3.5 x 10^3 Da. Tavares *et al* (2005) found that the molar mass of EPS obtained by gel permeation chromatography was ~6.7 x 10^4 Da. J-Y Oh *et al* (2007) produced exobiopolymer with molecular weight ranging 1.4 10^3 - 27 x 10^3 Da, using submerged culture of *Cordyceps sphecocephala.* Cui *et al*, (2007) reported molecular weight sub-fractions ranging from 3 x 10^3 to 2 x 10^6 Da isolated in EPS and IPS from *C. versicolor*, using size-exclusion chromatography coupled to a multi-angle laser light scattering device.

Results obtained in this study let us to confirm the interest of this selected culture medium, using tomato pomace, in order to maximise the production of protein-polysaccharide complexes by *C. versicolor.* Besides, this clean process allows valuing the agro-industrial residues with a low cost and a higher production of these polysaccharides compounds. The different polysaccharide concentration in endocellular and exocellular complexes shows that this *C. versicolor* strain produces different protein-bound polysaccharides, so further studies are being done in order to isolate and identify different *C. versicolor* complexes and investigate its bioactivity.

Abstract

The medicinal power and the nutritional value of some mushrooms are widely known. However, only in the last decades of the last century that it was possible to isolate and partially characterize some biologically active anti-cancer substances.

The therapeutic properties of mushrooms are attributed mainly to their polysaccharide content which has exhibited immunomodulatory properties such as anti-cancer, anti-viral and anti-bacterial activities. Protein-bound polysaccharides are macromolecules which consist of a central core protein to which are attached a number of polysaccharide chains and PSP and PSK from *Coriolus versicolor* are the most widely studied protein-bound polysaccharides.

Although protein-bound polysaccharides from mushrooms exhibit important medicinal properties, there is little information in the literature about their biological and physico-chemical properties.

Therefore, the aim of this work consists of production, purification and partial characterization of these protein-bound polysaccharides from *Pleurotus ostreatus* and *Lentinula edodes*.

The fungal strains were grown in several culture media such as whey permeate supplemented with glucose, yeast extract and suitable salts. The cultures were grown in agitated and aerated bioreactors at pH 5.5 and 27ºC, with pH and temperature control for 10 days and suitable daily samples were removed from the reactor. These samples were centrifuged and intracellular and extracellular protein-bound polysaccharides were extracted from the biomass and culture supernatant, respectively. Subsequently, these polysaccharides were purified by gel filtration chromatography on a Sephacryl S-300-HR column and fractions were analysed for protein, superoxide dismutase (SOD) activity and polysaccharides. Fractions containing protein-bound polysaccharides were characterized by HPLC which revealed UV and RI peaks with retention times of 6 and 13 min., respectively. On the other hand, FTIR analysis of these polysaccharide preparations revealed absorption peaks at 910, 989, 1078, 1644, 2335, 2363 and 3115 cm^{-1} which are characteristics of such macromolecules. Moreover, purified polysaccharides exhibited SOD activity which is in agreement with the data published in the literature.

The results presented strongly suggest that these basidiomycete strains produce high levels of free and protein-bound polysaccharides which exhibit similar physico-chemical properties compared with the data in the literature as far as HPLC and FTIR analysis are concerned.

Introduction

Mushrooms have been known to exhibit medicinal properties for thousands of years. Higher basidiomycete mushrooms have been used in clinical nutrition because they

exhibit antitumour, immune modulating, cardiovascular and anti-microbial activities (Parris, 2000). The benefits of mushroom nutrition on these clinical conditions has attracted great interest in the scientific community in the last decade in order to understand the molecular mechanism responsible for their action (Peng *et. al*., 2003).

There are several reports in the literature about production of free and protein-bound polysaccharides from basidiomycete strains such as *Coriolus versicolor*, *Letinula edodes* and *Ganoderma lucidum* (Parris, 2000). However, the physico-chemical properties of such polysaccharides are poorly investigated as far as pI, Mr, amino acid sequence of the protein portion and the nature of carbohydrate residues (Wang *et.al*. 2007: Cho *et. al*., 2006).

Moreover, it has been reported that polysaccharides exhibiting different structures have revealed different biological activities. On the other hand, hyperbranched polysaccharides have been poorly investigated as far as structure and function are concerned (Wang *et.al*. 2007: Cho *et. al*., 2006).

The use of agro-industrial residues (i.e tomato pomace, whey milk and rice husks) have not been studied in detail as carbon and nitrogen sources for production of these complex polysaccharides from basidiomycete strains in submerged fermentation. Therefore, the aim of this work consists of production, purification and partial characterization of these protein-bound polysaccharides from *Pleurotus ostreatus* grown by submerged fermentation.

Materials and Methods

Materials

Chemicals

Potato Dextrose Agar (PDA) medium and yeast extract were purchased from Oxoid (Hampshire, England). Milk whey was supplied from a local manufacturer. Glucose, benzamidine, phenol, Coomassie Blue G-250, urease, xanthine, nitro-blue tetrazolium were supplied by Sigma Chemical Company (S. Louis, MO, USA). Sephacryl S-300HR was purchased from Amersham Biotech (Sweden). Shodex Ohpak SB-804 HQ HPLC column was supplied from Showa Denko K.K. (Tokyo, Japan). Hemoglobin, peroxidise and xanthine oxidase were obtained from Biozyme Laboratories (Gwent South Wales, UK). All other reagents used were of analytical grade.

Microorganism

Pleurotus ostreatus was isolated from old growth forests of the Olympic Peninsula in Port Townsend, Washington (USA).

Methods

Production of polysaccharides from Pleurotus ostreatus

Pleurotus ostreatus was first grown on PDA and then transferred into the seed culture medium. The seed culture was grown in 250 mL flasks containing 50 mL of culture medium as follows: 2 % (w/v) glucose, 0.6 % (w/v) yeast extract, 0.3 % (w/v) $(NH_4)_2SO_4$, 0.2 % (w/v) KH_2PO_4, 0.05 % (w/v) $MgSO_4.7H_2O$ and 0.05 % (w/v) KCl and aqueous solution of milk whey 50 % (v/v) at 28 ºC on an orbital shaker at 200 rpm for 10 days as described previously (Cui *et al.*, 2007, Cho *et al.*, 2006). Biomass growth, protein and polysaccharides production were followed by taking aliquots of 50 mL of fermentation broth on the 4^{th}, 7^{th} and 10^{th} days of fermentation.

Isolation of extracellular and intracellular protein-bound polysaccharides

Mycelial biomass was separated from the fermentation broth by suction in a Buchner funnel as described previously (Cui *et al.*, 2007). Four volumes of 95 % (v/v) ethanol were added to the filtrated to precipitate the extracellular polysaccharides (EP). The EP were recovered by centrifugation (30 min, 10 000 rpm) and the precipitate was suspended in a minimum volume of 50 mM phosphate buffer pH 6.5 containing 1mM

benzamidine. The mycelial biomass suspension was incubated at 100 ºC for 2.5 h to release the intracellular polysaccharides (IP). The mixture was filtered by suction and the filtrate containing IP were recovered the same way as the EP recovery.

Protein and polysaccharide assays

EP and IP levels were quantified by phenol/sulphuric acid method using the polygalacturonic acid as a standard and protein quantification was carried out by the Comassie blue method.

Purification of polysaccharides by gel filtration chromatography

IP and EP were purified by gel filtration chromatography on Sephacryl S-300-HR column (1x100 cm) which was eluted with 50 mM phosphate buffer pH 7.0 at a flow rate of 40 mL/h. Column factions were analyzed for polysaccharides and protein contents and those fractions containing polysaccharides were selected to measure superoxide dismutase (SOD) activity.

The molecular weight of the protein-bound polysaccharides was also determined by gel filtration chromatography on a Sephacryl S-300-HR (detection range of molecular weight: $1 \times 10^4 - 1.5 \times 10^6$) column as described previously (Kim *et al.*, 2003). Urease, amidase, hemoglobin and peroxidase were used as protein standards.

HPLC analysis of polysaccharides

HPLC analysis was carried out by using Shodex column with 0.01 % (w/v) sodium azide as the solvent at a flow rate of 1 mL/min and at 80 ºC. Intracellular and extracellular polysaccharides extracted as described above, were injected (20 μL) and peak analysis was carried by UV and RI detectors.

SOD assay

Superoxide dismutase (SOD) assay was carried out at room temperature and the reaction mixture consisted of 0.1 M phosphate buffer containing 1.3 mM EDTA pH 8.0, xanthine, xantine oxidase and nitro-blue tetrazolium (NBT) and a suitable aliquot of polysaccharide was added to the sample and reaction was followed at 550 nm as described previously (Beuchamp and Fridovich, 1971). One unit of SOD is defined as the amount of SOD required to inhibit the rate of reduction of nitroblue tetrazolium by 50 % in a coupled system, using xanthine and xanthine oxidase at pH 7.8 at 25 °C in a final volume of 0.3 mL of reaction mixture. The xanthine oxidase concentration should produce an initial (uninhibited) rate of 0.005 per minute.

FTIR analysis of polysaccharides

Infrared spectra were recorded in a Bruker Tensor 27 FTIR spectrometer at 4 cm^{-1} resolution. Polysaccharide sample (40 μL) was transferred into a CaF_2 infrared cell, fitted with 25 μm path-length Teflon spacers and placed into the spectrometer.

Effect of heating on SOD activity and FTIR analysis

The column fractions exhibiting SOD activity were used to investigate the effect of heating on SOD activity. Suitable samples of SOD were placed in a water bath at 100 ºC and aliquots at suitable time intervals were removed from the water bath to an ice bath. SOD activity as well as FTIR analysis were determined as described in this paper.

Results and Discussion

Polysaccharides were produced by growing *Pleurotus ostreatus* in milk whey for 10 days, at 28 ºC in agitated flask at 200 rpm. Figure 1 presents the increase of biomass formation throughout the fermentation process as well as the increase in protein and polysaccharide concentration. As far as extracellular polysaccharides are

concerned, it is clear that there is a decrease in protein and polysaccharide concentrations after the 4th day of culture.

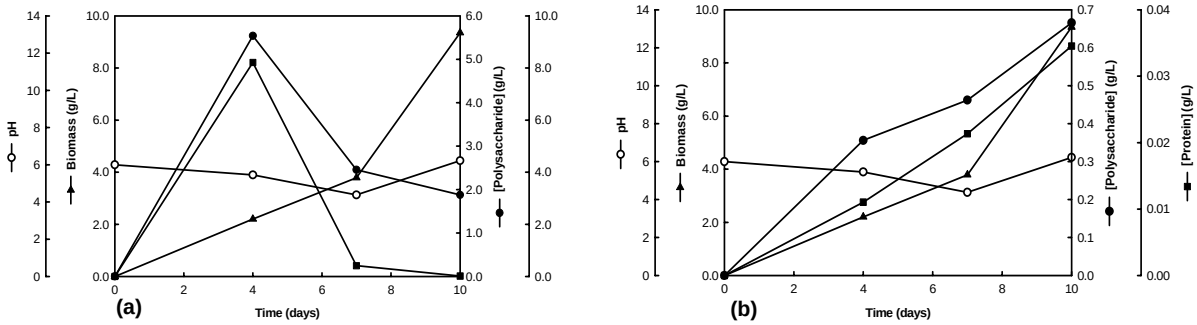

Fig. 1 – Fermentation profile showing variations of biomass growth, pH, polysaccharide and protein concentrations:. **(a)** Extracellular polysaccharides from *Pleurotus ostreatus;* **(b)** Intracellular polysaccharides from *Pleurotus ostreatus*

Fractions containing protein-bound polysaccharides were characterized by HPLC which revealed UV and RI peaks with retention times of 6 and 13 min., respectively (Figure 2).

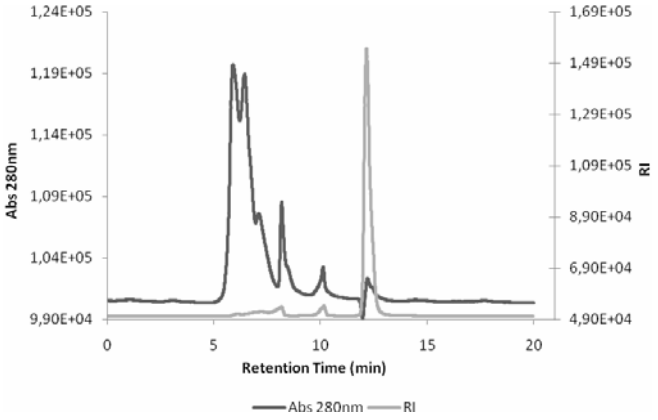

Fig. 2 – HPLC analysis of extracellular polysaccharides from *Pleurotus ostreatus.*

Extracellular polysaccharides were isolated by precipitation with alcohol and were purified by gel filtration chromatography on Sephacryl S-300-HR column (Fig. 3). According to this figure, there are several polysaccharide peaks whose Mr were determined by gel filtration chromatography (Table 1). Since there is a report in the literature that polysaccharides mimic SOD activity (Wang *et. al.,* 2007), some column fractions were selected to assay for SOD activity (Fig. 4). There is a correlation between SOD activity and polysaccharide content in such column fractions as shown in Fig. 4.

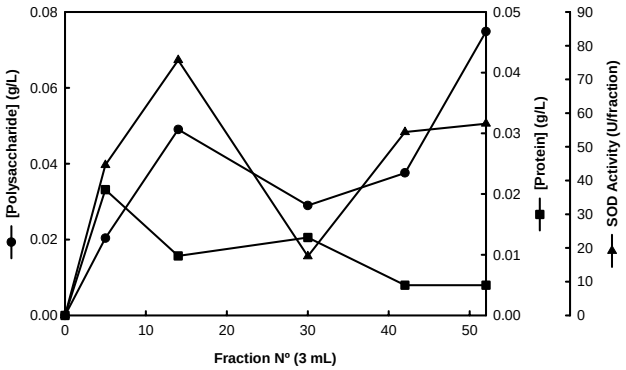

Fig. 4 – SOD activity of some selected fractions from gel filtration chromatography exhibiting protein and polysaccharide contents Concentration variation of protein and polysaccharides in relation to SOD activity in selected gel filtration chromatography fractions.

Fraction Nº.	[Protein] (mg/L)	[Polysaccharide] (mg/L)	Mr (kDa)
5	20.4	20.7	848.7
14	49.0	9.8	517.7
30	29.0	12.8	215.0
42	37.6	5.0	111.2
52	74.8	5.0	64.2

Table 1 - Polysaccharide and protein concentration as well as Mr values for some selected fractions of gel filtration chromatography.

In order to investigate the nature of SOD mimicking activity of these polysaccharides, we studied the effect of heating on some selected column fractions exhibiting SOD activity. Surprisingly, the heating at 100 ºC of polysaccharide fractions exhibited an increase in SOD mimicking activity as shown in Fig. 5. Moreover, the effect of time of heating of such polysaccharide fractions on SOD activity was also investigated which revealed that there was an increase in SOD mimicking activity with time of heating (Fig. 6).

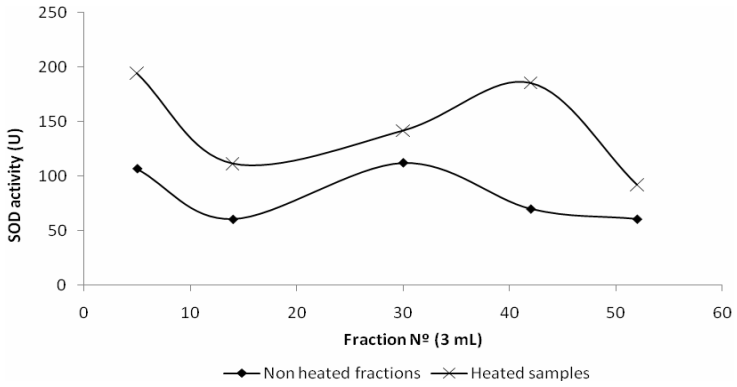

Fig. 5 – Variation of the SOD activity in selected fractions of gel filtration chromatography submitted to heat treatments. (- non-heated.; - heated at 100°C for 15 minutes).

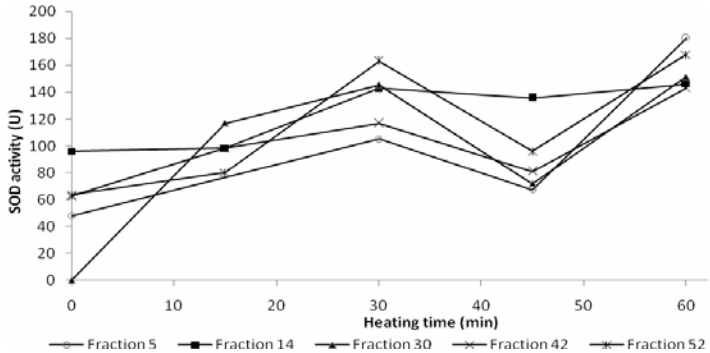

Fig. 6 – Variation of the SOD activity in selected fractions of gel filtration chromatography submitted to heat treatments. (- non-heated.; - heated at 100°C for 15 minutes).

Moreover, the increase in SOD mimicking activity was also investigated by FTIR analysis which exhibits an increase in absorption of several peaks at 910, 989, 1078, 1644, 2335, 2363 and 3115 cm^{-1} (Fig 7).

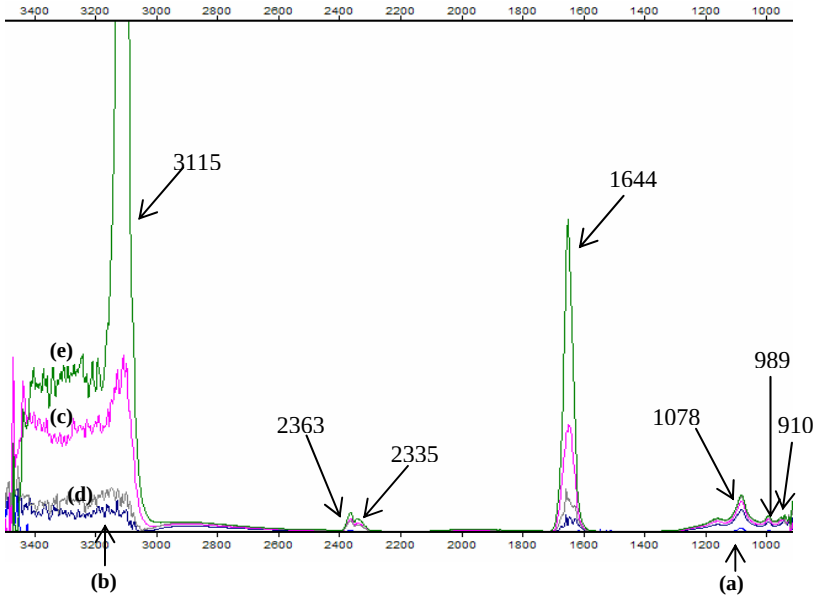

Fig. 7 – FTIR spectrum of a column fraction exhibiting SOD activity. Effect of heating time of a column fraction at 100 ºC on FTIR spectrum (**(a)** non- heated sample; **(b)** 15 minutes; **(c)** 30 minutes; **(d)** 45 minutes; **(e)** 60 minutes).

Keywords: HS - SPME, GC - MS, *Candida* species, isoamyl alcohol, 2-phenylethanol
Topic: Integration of life sciences & engineering

Abstract

Aim: This study aimed to identify and quantify the fusel alcohols secreted by the opportunistic yeasts *Candida albicans* and *Candida dubliniensis* to further get insights into the amino acid catabolism of those two organisms.

Methods and Results: Fusel alcohols were screened in cell - free supernatants of yeasts cultivated in RPMI medium. For simultaneous identification and quantification of these alcohols, a Headspace - Solid Phase Micro Extraction (HS - SPME) coupled with gas chromatography - mass spectrometry (GC - MS) methodology, previously developed to analyse the volatile composition of fruits, was followed (Coelho et al. 2006). Results obtained show that both *C. albicans* and *C. dubliniensis* produced isoamyl alcohol and 2-phenylethanol, end – products of the catabolism of the amino acids leucine and phenylalanine, respectively.

Significance and Impact of the study: The HS – SPME used herein allows the simultaneous identification and quantification of compounds, requires small sample volume, has high sensitivity and reproducibility, is simple and rapid and is solvent free. This revealed to be a powerful tool for the screening system of yeast metabolic compounds.

1 Introduction

The recognition that the catabolism of amino acids to their respective fusel alcohols plays an important role in (off-) flavour and aroma of yeast fermented products motivated the scientific interest in this field. Whereas in most eukaryotes the carbon skeletons derived from amino acids enter the tricarboxylic acid cycle, in the yeast *Saccharomyces cerevisiae* the degradation of the aromatic amino acids (tryptophan, phenylalanine and tyrosine) and the branched-chain amino acids (valine, leucine and isoleucine) occur through the Ehrlich pathway (recently reviewed by Hazelwood et al. 2008). This pathway comprises an initial step of transamination of the amino acid to the corresponding α-keto acid, followed by its decarboxylation to the respective aldehyde and the reduction of the aldehyde to form the corresponding fusel alcohol. Research developed so far aimed to identify (1) the end - products of amino acids catabolism, (2) the enzyme(s) involved in the metabolic process and (3) the bioactivities of fusel alcohols (Dickinson 1996;Dickinson et al. 1997;Dickinson et al. 2003).

Despite the efforts done to identify metabolites in yeast/ fungal extracts, there is a scarce knowledge concerning the metabolism of amino acids in *Candida albicans* and *Candida dubliniensis*, two closely related opportunistic fungal pathogens. A number of techniques have been employed for fungal metabolites profiling including paper chromatography, thin layer chromatography, capillary electrophoresis and the mainly applied high performance

liquid chromatography (HPLC) and gas chromatography - mass spectrometry (GC – MS) (Frisvad et al. 2008). Although chromatographic methods are very sensitive and selective their major disadvantage is the need of sample preparation. Traditional methods used for sample concentration and purification are time consuming, expensive and require a large volume of hazardous organic solvents (Lanças 2003). However, in the beginning of the last decade solid phase microextraction (SPME) technology was introduced to overcome some of these difficulties. SPME is a microextraction technique based in a equilibrium partition of the compounds between the sample matrix and the extracting phase, a polymer-coated fused fiber and can be directly coupled with HPLC or GC - MS (Arthur and Pawliszyn 1990). This technique was successfully applied for polar and non - polar compounds in gas, liquid and solid samples from environmental or biological sources (Ulrich 2000).

The objective of this work was to identify and quantify the fusel alcohols: isoamyl alcohol and 2-phenylethanol, secreted by *C. albicans* and *C. dubliniensis*, using headspace - SPME coupled with GC – MS, to further get insights into the amino acid catabolism of those two microorganisms.

2 Material and Methods

Chemicals. Standard alcohols were obtained from Sigma. Isoamyl alcohol stock solution was prepared in water whereas the 2-pheneylethanol was prepared in methanol.

Organisms. Two *Candida* species were used in this study: *C. albicans* CECT 1472 (Colección Española de Cultivos Tipo, Spain) and *C. dubliniensis* CBS 7987 (Centraalbureau voor Schimmelcultures, Germany).

Media and culture conditions. Prior to each experiment, both *Candida* species were maintained at 37°C in Sabouraud dextrose agar. After, cells were grown in Sabouraud dextrose broth at 37°C for 24 h on a mechanical shaker at 130 rpm. Subsequently, cells were washed twice with ultrapure water and counted in a hematocytometer. Standardized cell suspensions were prepared at a cell density of 1×10^6 cells/ml in 1×RPMI 1640 medium (Sigma) buffered with morpholinepropanesulfonic acid (MOPS– Sigma) (final concentration 0.165 M for pH 7.0). For culture supernatants preparation, 120 ml of standardized cell suspensions were inoculated in 300 ml flasks and incubated at 37°C, 130 rpm. After 24 h cell – free supernatant fractions were filter sterilized (0.22 µm) and stored at 4°C.

Biomass dry weight measurements. At the end of incubation, 1 ml of the planktonic culture was filtered through pre-weighted filters (0.45 µm) and washed three times with ultrapure sterilized water. Filters were dried at 60°C until constant weight and cell dry weight (CDW) was determined. This was repeated at least four times.

Supernatant alcohols analyses. Supernatant fusel alcohols were extracted using HS - SPME and analysed by GC - MS using a method adapted from Coelho et al. (2006). Supernatant fractions (20 ml) were introduced into a 60 ml bottle, together with 4 g of NaCl and a 20 × 5 mm stirring bar. After sealing the vial with a teflon septum and an aluminium cap, it was placed in a water bath at 40±0.1 ºC for a period of 15 min (200 rpm) to transfer the compounds from the sample to the headspace. The headspace volatiles were extracted along 45 min with a SPME carbowax-divinylbenzene fused silica fibre (CW-DVB, 65 µm- Lot P334957) (Supelco). The GC - MS parameters were established according to Coelho *et al*. (2006). *Candida* fusel alcohols were identified by comparison of their mass spectra and retention times with those of data system library (Wiley 275) and of reference substances. A control analysis was done with growth medium. Compounds quantification was performed by preparation of RPMI solutions containing pure standards and using the same conditions applied to samples. For each compound appropriate concentration ranges were chosen in order to include sample concentrations. All measurements were made with, at least, two

replicates. Blanks, corresponding to the analysis of the coating fibre not subjected to any extraction procedure, were run between sets of three analyses. Alcohols analyses were carried out in duplicate for each sample with results agreeing within ≤ 15 %.

3. Results and Discussion

RPMI 1640 medium was chosen as growth medium. This medium contains all 20 amino acids and nitrate but not ammonium ions. This combination may force *Candida* cells to get its nitrogen from amino acids and in the process secrete fusel alcohols such as isoamyl alcohol (from leucine) and 2-phenylethanol (from phenylalanine). Establishment of the HS - SPME methodology for the identification and quantification of these compounds in *C. albicans* and *C. dubliniensis* cell – free supernatants will be presented and discussed below.

Establishment of the HS - SPME GC - MS methodology

Fiber selection. The fiber polarity, porosity and surface area are critical parameters in SPME, thus several types of coating fibers with different film thicknesses are commercially available (1998b). In this study, a 65 µm CW - DVB fused silica fibre was used. The CW - DVB coating fibre is recommended for small and polar molecules (molecular weight between 40 and 275). The CW - DVB coating fibre was selected because it is a mixed coating that contains a liquid polymer and solid particles. This type of coating combines the absorption properties of the liquid polymer with the adsorption properties of porous particles, which are composed of macro (>500 Å), meso (20-500 Å) and microporous (2-20 Å). The mutually synergetic effect of adsorption and absorption to the stationary phase promotes a high retention capacity and, consequently, a higher sensitivity than fibres based on absorption only (Kataoka et al. 2000).

Extraction mode. Compounds extraction can be achieved exposing the fiber in the headspace (vapour phase) surrounding the sample, headspace (HS) - SPME, or introducing it directly in the sample matrix, direct immersion (DI) - SPME (Zhang and Pawliszyn 1993). In HS - SPME mode equilibrium is attained more rapidly and the prevention of the fiber direct contact with the sample minimizes background noise and can extend the fiber life time. Additionally, HS - SPME is more sensitive for the analysis of volatile compounds of complex matrices (Kataoka et al. 2000). In this work the HS - SPME mode was used. In a three system analysis (sample – headspace – CW - DVB coating fiber), the transference occurs from the liquid matrix to the headspace, and from that to the coating fiber, which promote the sorption of the compounds in the coating fiber.

Extraction conditions and sample modification. In general, sample volumes used in SPME extraction range from 4 to 120 ml (Krutz et al. 2003). In contrast, traditional techniques such as the described by Hornby et al. (2001) for the purification of farnesol from *C. albicans* cell – free supernatant require larger sample volume, specifically five litres. In SPME the amount of compound extracted and/or the extraction time can be increased by manipulation of some parameters. First, stirring liquid samples facilitates the transfer of the compounds to the coating fiber. Second, as a typical guideline, sample modification by the addition of a soluble salt such as NaCl or Na_2SO_4 decreases compound solubility in the matrix, favouring its extraction onto the fiber due to the salting – out effect. Third, for HS - SPME the compound concentration in the vapour phase is dependent on the extraction temperature, and samples are usually heated (Kataoka et al. 2000). Thus, over this study, all samples were extracted using a magnetic stirring for agitation that was maintained at 200 rpm, after the addition of 4 g of NaCl of 20 ml of sample and in a water bath operating at 40±0.1 ºC. In order to achieve accurate and precise analyses, sampling parameters such as sampling time, vial size, magnetic bar size and sample volume were kept constant (see Material and Methods section) intra and inter assays. The extraction procedure was completed within one hour/ sample, demonstrating that SPME is a rapid technique.

Fusel alcohols discrimination. Prior to sample analysis, the methodological approach described was tested using a standard mixture containing isoamyl alcohol and 2-phenylethanol (Figure 1). Under the GC - MS conditions used (Coelho et al. 2006), the signal (total ion current) obtained exhibited resolved peaks at 9.5 min for isoamyl alcohol (Figure 1, I) and at 55.7 min for 2-phenylethanol (Figure 1, II), demonstrating that this is a rapid screening procedure for the simultaneous extraction and identification of these compounds.

.External standardization. The quantitation approach when using SPME is dependent on the sample matrix, its complexity and extraction method being used. In the case of a liquid and simple sample an external standard calibration is recommended (1998a). Standard mixtures were prepared in a clean matrix sample (RPMI medium) and analysed under the same conditions as those of samples. This allows the GC peak area data to be used as an indirect approach to estimate the relative content of each compound. Standard curves were generated for GC - MS peak areas versus concentration of each compound (R^2>0.98). Estimated limit of quantification (LOQ) and limit of detection (LOD) were: 0.08 mg/l and 0.02 mg/l for isoamyl alcohol and 0.04 mg/l and 0.01 mg/l for 2-phenylethanol. Thus, using quantitative HS – SPME GC – MS a linear response was obtained for a wide range of concentrations and the LOD levels were found suitable for the analysis (see below).

HS - SPME GC - MS *Candida* sample analyses

Qualitative analysis. The growth medium was analysed for possible interference and was shown to have no interfering compounds into or near the retention times of those compounds (Figure 2, I). Figure 2 (II) shows a typical chromatogram obtained for *C*. *albicans* and *C. dubliniensis*. Comparison of GC retention times and mass spectra of pure standard compounds (such as those presented in Figure 1) allowed the identification of isoamyl alcohol and 2-phenylethanol in these two samples, showing that these two fusel alcohols are produced and secreted into the extracellular medium by *C. albicans* and *C. dubliniensis*.

Quantitative analysis. The detector response from the sample was compared to the response from the target compounds in the calibration curve. Values were standardized against cell dry weight. In *C. albicans* cell - free supernatants isoamyl alcohol was found at 5.65 mg/ g of CDW and 2-phenylethanol at 0.90 mg/ g of CDW. For *C. dubliniensis*, fusel alcohols concentrations (mg/ g of CDW) were: 6.06 for isoamyl alcohol and 1.88 for 2-phenylethanol. This evidences that quantitative HS – SPME GC – MS using matrix-matched calibration curves allowed determination of both fusel alcohols in *Candida* spp samples.

Conclusion

The HS - SPME is a microextraction technology that combines sample preparation and pre-concentration into one single step. The HS – SPME strengths include: (i) the simultaneous identification and quantification of compounds, (ii) small sample volume requirements, (iii) high sensitivity and reproducibility, (iv) simplicity, (v) speed, (vi) no solvent needs. Moreover, it is compatible with compound separation and detection by several systems and it can be automated. This sampling technology revealed to be a powerful tool for the screening system of yeast metabolic compounds.

Topic: Biological Process System Engineering.

Abstract

Finding optimal operating conditions fast with a scarce budget of experimental runs is a key problem to speed up the development and scaling up of innovative bioprocesses. In this paper, a novel iterative methodology for model-based design of dynamic experiments in modeling for optimization is developed and successfully applied to the optimization of the production of interleukin-11 (IL-11) whose DNA sequence has been cloned in an *Escherichia coli* strain. At each iteration, the proposed methodology resorts to a library of models to increasingly bias operating conditions by selecting the *'most informative'* model for designing the next dynamic experiment consisting of an improved operating policy and optimal sampling times. Model selection is done by computing an error measure which distinguishes between parametric and structural uncertainty to selectively bias data gathering towards optimal operation. Parametric uncertainty is iteratively reduced using Global Sensitivity Analysis (GSA) to pinpoint which parameters are key for estimating the objective function. Results obtained after just three iterations are very promising.

1 Introduction

Today, many pharmaceuticals and high-value specialty products are obtained using genetically modified microorganisms. Since the first gene cloning in the beginning of the 1970s, it is possible to modify a microorganism to produce a desired substance, often a protein. To cope with a steadily increasing demand for biotech products along with fierce worldwide competition issues such as lowering downstream costs, shorten time to market of new products and improving productivity of installed capacity and culture broth should be addressed.

Bioprocess modeling and optimization is a challenging task due to the complexity of both of metabolic regulation and organism's reactions that follow to changes in the cell environment as a consequence of the implementation of an operating policy. As a result, several modeling strategies have been proposed which have different characteristics; for example, it can be found from purely statistical modeling methods to highly structured ones. Although those approaches are very valuables, many of them have shown inherent failures derived from basic assumptions done in model building and in some cases their detailed development could be costly and very time consuming. Keeping above considerations in mind, a new point of view called *modeling for optimization*, which has been developed for batch processes in general, is being now explored for fast experimental optimization of bioreactor operation.

2 Methodology

Modeling for Optimization is a systematic approach for biasing data gathering using one or several first-principles models of a given process with the explicit objective of improving its operating condition. Taking advantage of a library of first-principles models this method reduces uncertainty in extrapolation when the process is driven to unknown operating regimes. In this contribution, a methodology for iterative design of dynamic experiments in modeling for optimization methods will be presented using a case study related to the production of a recombinant peptidic hormone rIL-11. For each iteration, a dynamic experiment is designed using a selected model. This selection is based on a novel uncertainty measure in which both structural and parametric model uncertainty is computed using Global Sensitivity Analysis (GSA) (Saltelli *et al.*, 2004). The designed dynamic experiment consists of an operation policy $\hat{\wp}(\hat{w},t)$ and optimal sampling times ψ^{opt} along a modeling run. The experiment is carried out and new data is collected. Before proceeding to (re)estimate model parameters, the sensitivity of the performance index with respect to model parameters is assessed using GSA. This allows using new data more effectively to reduce parametric uncertainty in the subset of model(s) parameters which is the most relevant for policy improvement. A complete iteration of the proposed approach for integrating model development with dynamic optimization using a sequence of designed experiments is shown in the Fig. 1.

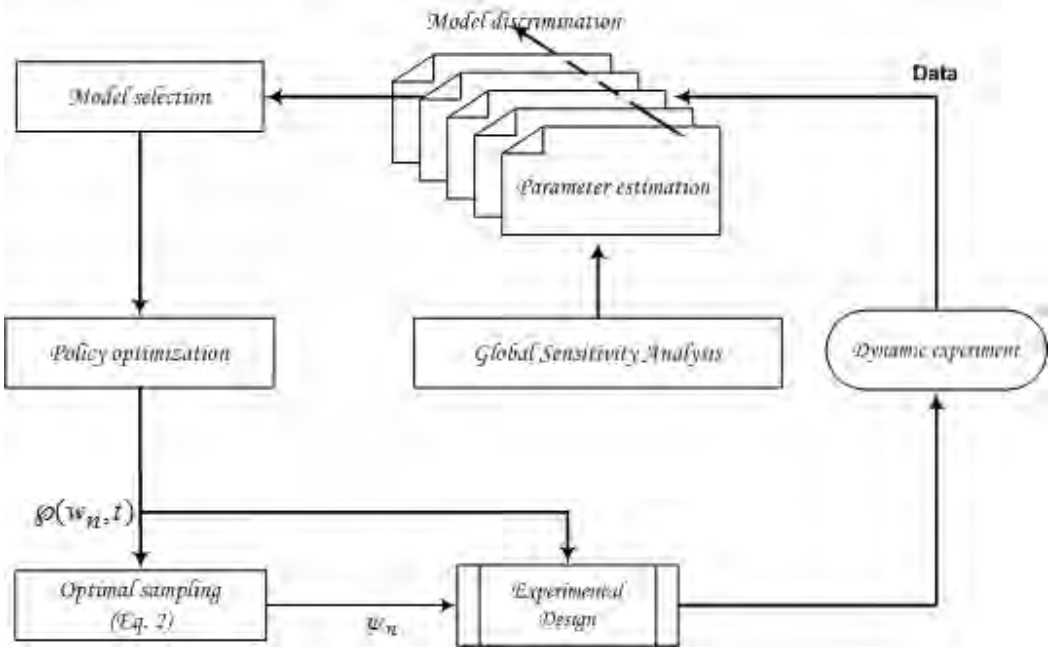

Figure 1. Iterative Model-based Design of Dynamic Experiments for Optimization

Given a set of ℓ alternative models for the process defined as

$$\frac{dx}{dt} = f_\ell(x(t), \wp_k(w,t), \theta^\ell, t),\ J(t_f) = h(x(t_f), \wp_k(w,t), t),\ \ell = 1,...,M \qquad (1)$$

where $x(t)$ are the state variables, $\wp_k(w,t)$ is the operating policy at the *kth* iteration defined upon a set of parameters *w* and time *t* where θ^{ℓ} are parameters of the ℓth model whose uncertainty is characterized by Θ^{ℓ} and J is the objective function to be optimized.
To improve the current operating policy, experimental data (dynamic experiment) is needed to suitably reduce parametric uncertainty in each model. To this end, it is important to determine when along the run each of the n_{sp} sampling times should be located in order to obtain the sampling points times $\psi^{opt} \in \Psi$ which are the most informative in modeling for optimization in the face of uncertainty. Optimal sampling is formulated as the following optimization problem:

$$\psi^{opt} = \max_{\psi \in \Psi} \left| M(\hat{\theta}, \wp_k, \psi) \right|, \; M = Q^T Q$$
$$Q = \begin{pmatrix} S_{11} & \cdots & S_{1n} \\ \vdots & \ddots & \vdots \\ S_{m1} & \cdots & S_{mn} \end{pmatrix} \tag{2}$$

where the entries of the matrix Q , S_{ij}, measure the sensitivity of the performance index J at the *ith* sampling time with respect to *jth* policy parameter. Once sample data from the dynamic experiment is available, the first question is how to selectively improve parameter precision of alternative models. To address this issue, GSA techniques (Saltelli *et al.*, 2004) are used to identify for each model the subset of parameters to which the objective function J is most sensitive. Having reduced parametric uncertainty, for improving the operating policy a model must be selected.

In this work, model selection is based on distinguishing between parametric uncertainty and structural errors in performance prediction using alternative models. For the *rth* realization of model parameters, the corresponding simulated trajectory of process performance is $\hat{J}_r$. At each sampling point, a sample average $\left\langle \hat{J} \right\rangle$ of different realizations can be used to characterize parametric uncertainty for each model as follows (Asprey 2000; Asprey and Machietto, 2002; Chen and Asprey, 2003):

$$\varepsilon_{\hat{J}_i \to \left\langle \hat{J}_i \right\rangle} = \frac{1}{n_{sp} n_{\rho}} tr\left[\left(\frac{\hat{J}_{ir} - \left\langle \hat{J}_i \right\rangle}{\left\langle \hat{J}_i \right\rangle} \right)^T W_{ir} \left(\frac{\hat{J}_{ir} - \left\langle \hat{J}_i \right\rangle}{\left\langle \hat{J}_i \right\rangle} \right) \right]; i = 1,2,..., n_{sp}; r = 1,2,..., n_{\rho} \tag{3}$$

where W_{ir} is weighting matrix. As parametric uncertainty is iteratively reduced the importance of structural errors in each model regarding performance predictions are more evident when the operating condition is change in the search for policy improvement. As a measure of structural uncertainty, the average performance trajectory $\left\langle \hat{J}_i \right\rangle$ is compared at *ith* sampling point to the actual trajectory J_i to define the structural error:

$$\varepsilon_{\left\langle \hat{J} \right\rangle \to J} = \frac{1}{n_{sp}} tr\left[\left(\frac{\left\langle \hat{J}_i \right\rangle - J_i}{J_i} \right)^T W_{ii} \left(\frac{\left\langle \hat{J}_i \right\rangle - J_i}{J_i} \right) \right]; i = 1,2,..., n_{sp}; W_{ii} : weighting \;\; matrix \tag{4}$$

The total error of the ℓth model can be expressed as a weighted sum of errors in (3) and (4). Model selection may simply be done so that the model whose total error is the lowest is chosen for policy optimization. More elaborated strategies for model selection can also be developed. For example, initially model selection may emphasize reducing parametric uncertainty and as more data are gathered model selection is based on structural errors.

3 Case of study

To illustrate the proposed methodology, results obtained in the optimization of fed-batch fermentation process for the recombinant protein **rIL-11** using a genetically modified *E. coli* strain are presented. A structured kinetic model proposed by Tang *et al*. (2007) which describes state variables trajectories such as: biomass (*X*), substrate (*S*), intracellular recombinant protein concentration (*P*) will be used as an *in silico* bioreactor. Four unstructured models which differ in their biomass growth kinetics are used as guidelines for optimization so that the mismatch between "real" bioprocess and alternative models of the bioreactor is accounted for. Also, the operation policy has been defined based on the substrate feeding rate and induction time as the main components subject to optimization, including the initial culture condition. The basic model equations and the alternative biomass growth kinetics are:

$$\frac{dX}{dt} = \mu X; \quad \frac{dS}{dt} = -\frac{\mu}{Y_{xs}} X - f(X,t); \quad \frac{dP}{dt} = r_P - \mu P \tag{5}$$

$$r_P = \begin{Bmatrix} 0, & t \geq t_{ind} \\ K_P^{\max}\left(\frac{S}{K_s + S}\right)\left[\frac{1}{1+\left(\frac{P}{KI_P}\right)^5}\right], & t \geq t_{ind} \end{Bmatrix}$$

$$\text{Pr } imer\ orden: \quad \mu = \mu_{\max} S; \qquad f(X,t) = 0$$

$$Monod: \quad \mu = \mu_{\max} \frac{S}{K_S + S}; \qquad f(X,t) = 0$$

$$Contois: \quad \mu = \mu_{\max} \frac{S}{K_X X + S}; \qquad f(X,t) = 0$$

$$Manteinance: \quad \mu = \mu_{\max} \frac{S}{K_S + S}; \qquad f(X,t) = mX$$

Based on experimental data provided by Tang et al. (2007), a rough estimation of each model parameters was made and referred to as "initial values" in Table 1. Due to the significant level of parametric uncertainty a ±50% confidence interval around these initial values for each parameter is assumed for the first iteration. Moreover, a uniform distribution over its confidence interval is assumed for each parameter. In Table 2, parametric and structural errors for each model are given for the first two iterations. The total error is calculated by providing the same weight to parametric uncertainty and structural errors. It is worth noting that parametric uncertainty is so high at the beginning of the study that structural errors are almost no informative until an actual performance trajectory is available which is clear in the 2nd and 3rd iterations.

According to Table 2 the *Monod* model should be chosen for designing the first dynamic experiment since it exhibits the minimum parametric and structural errors. The optimal operation policy is computed by assuming the following feeding time profile:

$$F(t) = A\frac{t'}{1 + Bt' + Ct'^2}; \quad t' = t - t_{feed} \tag{6}$$

where upper and lower bounds for policy parameters A, B and C have been defined so that the total fed volume to the bioreactor does not exceed 10L while minimizing the correlation among them. The optimized policies obtained for the three iterations are shown in Table 3.

Table 1: Model Parameter (re)Estimation

		Initial values				Re-estimation

Table 2: Errors for different models (initial process condition)

Model	Initial Condition			1st iter			2nd iter		
	$E_{\hat{J}_i \to \langle \hat{J} \rangle}$	$E_{\langle \hat{J} \rangle \to J}$	E_{total}	$E_{\hat{J}_i \to \langle \hat{J} \rangle}$	$E_{\langle \hat{J} \rangle \to J}$	E_{total}	$E_{\hat{J}_i \to \langle \hat{J} \rangle}$	$E_{\langle \hat{J} \rangle \to J}$	E_{total}
1st Order	0.4748	0.0149	0.4896	0.1529	0.5976	0.7506	0.0174	0.3730	0.3904
Monod	0.3352	0.0037	**0.3388**	0.1915	0.3441	0.5356	0.1159	0.0156	**0.1315**
Contois	0.4469	0.0033	0.4502	0.6558	0.3804	1.0362	0.0432	0.2287	0.2719
Manteinance	0.3382	0.0075	0.3457	0.0891	0.3018	**0.3909**	0.0343	0.5499	0.5842

Optimal sampling times for designed dynamic experiments in each iteration were:

$$\psi_{1st}[h] = [1.83,\ 2.33,\ 3.33,\ 4.00,\ 5.00,\ 5.50,\ 7.33,\ 11.33,\ 11.83,\ 12.33,\ 13.67,\ 15.67]$$
$$M = 1.93 \cdot 10^{-20}$$

$$\psi_{2nd}[h] = [0.17,\ 0.83,\ 1.33,\ 2.00,\ 3.50,\ 4.17,\ 5.33,\ 5.83,\ 11.17,\ 11.83,\ 12.33,\ 13.17]$$
$$M = 1.61 \cdot 10^{-24}$$

$$\psi_{3rd}[h] = [1.00,\ 2.50,\ 3.83,\ 4.33,\ 5.00,\ 6.00,\ 8.00,\ 12.17,\ 12.66,\ 13.33,\ 13.83,\ 14.33]$$
$$M = 1.91 \cdot 10^{-22}$$

Normalized Global Sensitivity Indexes for models parameters after each experimental run have been computed and later the most uncertain were re-estimated using experimental data from *in silico* bioreactor (data not shown). Re-estimated values for parameters and their 95% confidence intervals are shown in Table 1.

Table 3: Optimun Operation Policies for E. coli culture for rIL-11

Parameter	Units	Minimum	Maximum	Initial	1st run	2nd run	3rd run
A	$L\ h^{-2}$	$2\ 10^{-3}$	1.1	-	0.0569	0.0545	0.0569
B	h^{-1}	$3\ 10^{-4}$	0.1	-	$3\ 10^{-4}$	$3\ 10^{-4}$	$3\ 10^{-4}$
C	h^{-2}	$3\ 10^{-4}$	0.1	-	$3\ 10^{-4}$	$3\ 10^{-4}$	$3\ 10^{-4}$
S_f	$g\ L^{-1}$	5	30	-	30	30	30
t_{feed}	h	0	5	-	0	0	0
t_{ind}	h	3	7	-	4	4	4
t_f	h	8	16	10	16	16	16
V_0	L	5	10	8	5	5.30	5
X_0	$g\ L^{-1}$	0.01	0.1	0.05	0.1	0.1	0.1
S_0	$g\ L^{-1}$	2	7	5	7	3	6.5
			$J(g)$	**1.09**	**7.12**	**6.44**	**7.10**
			std(J)[g]		0.32	0.12	0.09

The iterative improvement methodology has been finished after the 3rd dynamic experiment since, as shown in Table 3, no further improvement is gained and the operating policy converges. Furthermore, it can easily be seen that the method deals very well with the objective of improving the final amount of rIL-11 obtained in a single run. Furthermore, the uncertainty in the objective function prediction has been significantly reduced by selectively re-estimating model parameters after each experiment.

4 Concluding remarks

A systematic methodology for designing optimally informative dynamic experiments in modeling for optimization based on several approximate models have been proposed. Results obtained in the production of interleukin-11 (IL-11) case study are very promising and industrial applications in the development of novel specialty-chemicals and bioprocesses are currently underway.

Topic: Integration of life sciences & engineering

Abstract

This paper presents experimental observations and a theoretical study of the dynamic behavior of the fed-batch alcoholic fermentation for ethanol production, utilizing the *Saccharomyces cerevisiae* Y904 yeast and operational conditions equivalent to the adopted in Brazilian industries. The influence of substrate concentration and feeding rate on yield and productivity is discussed and the parameters estimation of two kinetic models through an Differential Evolution algorithm associated to the correlation and parametric sensitivity analysis are presented. The first model (Tosetto, 2002) considers the inhibition effects by substrate and product and the second is the classical Monod model. The parameters μ_{max} and K_S present the highest sensitivities. The Monod model was validated to a fed-batch fermentation with sucrose concentration and feeding rate 277.0 g/L and 1.166 L/h respectively with good results.

1 Introduction

The biofuels production has increased significantly in the last years. In 2006 the global production was about 40 M ton. of ethanol, being Brazil the major producer of alcohol from sugarcane, produced on 1% of the Brazilian arable land. There is no competition between ethanol and food segment in the country and besides it its energy balance is highly positive.

The fermentation processes can be operated in batch, fed-batch or continuous mode. The fed-batch operation is preferable when high substrate levels inhibit the product formation and there is production of undesired components. In these circumstances changes in the feeding rate of the substrate affect the productivity and the yield of the desired product so that the determination of the feeding policy that maximizes the ethanol production becomes a priority (Arpornwichanop and Shomchoam, 2007; Xiong *et al.*, 2007). The definition of the reaction kinetic is dependent of the operation mode used (Baltes *et al*.,1994; Pertev *et al.*, 1997; Wang and Sheu, 2000) and its determination in equivalent conditions to that utilized industrially is fundamental for the modeling, simulation and dynamic optimization of these processes. However, the parameter estimation from experiments still remains as an obstacle for a major advancement in biochemical processes (Rodriguez-Fernandez *et al.*, 2006).

In this paper the *Saccharomyces cerevisiae* Y904 yeast was used for fermentation with different combinations of sucrose concentrations and feeding rates to study the dynamic behavior of the fed-batch alcoholic fermentation for ethanol production. Despite recent studies which demonstrate that *Zymomonas mobilis* bacteria supplies a major yield when compared with the *S. cerevisiae* yeast (Lin and Tanaka, 2006; Bai *et al.*, 2008), this bacteria presents constraints about the substrates utilized (Bai *et al.*, 2008) and is not economically

*Corresponding author. Tel +55 (02134) 3239-4292 Ramal 229. E-mail: valeria@ufu.br

competitive with the yeast. So, its generalized application in Brazilian industries is not expected. The parameter estimation of the non-structured kinetic model proposed by Tosetto (2002) and of the classical Monod model was obtained through the Differential Evolution algorithm of Storn and Price (1996), available at http://www.ICSI.Berkeley.edu/~storn/code.html, considered more competitive for the global optimization despite demands a major number of evaluations of the Objective Function (Rodrigues-Fernandes *et al.*, 2006). The parametric sensitivity analysis and the estimate of the correlation matrix were realized through DDASPK code of Petzold *et al.* (2000) and of the methodology proposed by Sanz and Voss (2006), respectively.

2 Materials and Methods

The yeast used was the *Saccharomyces cerevisiae* Y904 strain. The composition of the cultivate medium consisted of sucrose with concentrations in the range 217 - 285 g/L; KH_2PO_4 (5 g/L); $MgSO_4.7H_2O$ (1 g/L); NH_4Cl (5 g/L); KCl (1 g/L) and yeast extract (6 g/L). The temperature, pH and agitation were set at 32 ºC, 4.50 and 200 rpm. The fermentations were performed using a 5 L bioreactor (New Bioflo 110 Brunswick Scientific CO). The inoculum volume was 1.5 L and corresponded to 30% of the bioreactor volume with initial cell and ethanol concentrations about 86 g/L and 4% (v/v) respectively. The ethanol and biomass concentrations were determined by dry biomass and spectrophotometric methods (Steckelberg, 2001) and the glucose concentration by glucoseoxidase test.

The Equations 2.1-2.4 present the dimensionless balances of cells (X), substrate (S), product (P) and volume (V) for the fed-batch bioreactor, where the characteristic scales were the initial and maximum values of the state variables (x_0, s_F and v_{max}), the ethanol concentration where there is greater cellular growth inhibition (p_{max} = 115 g/L, Ferreira, 1998) and the total fermentation time (Dutta *et al.*, 2001; Popova and Boyadjiev, 2007). The unstructured kinetic model presented in Eq. 2.5 was developed by Ghose and Thyagi (1979) and modified by Tosetto (2002) and considers the parabolic inhibition by both substrate and product with the power n different of one. Eq. 2.6 presents the classical Monod model.

$$\frac{dX}{d\tau} = -\frac{F_a}{V}X + \mu X \qquad (2.1)$$

$$\frac{dS}{d\tau} = \frac{F_a}{V}(S_F - S) - \left(\frac{1}{Y_{XS}}\mu + M_S\right)X \qquad (2.2)$$

$$\frac{dP}{d\tau} = -\frac{F_a}{V}P + \frac{Y_{PS}}{Y_{XS}}\mu X \qquad (2.3)$$

$$\frac{dV}{d\tau} = F_a \qquad (2.4)$$

$$\mu = \mu_{max}\left(\frac{S}{K_S + S + \frac{S^2}{K_i}}\right)\left(1 - \frac{P}{P_{max}}\right)^n \qquad (2.5)$$

$$\mu = \mu_{max}\left(\frac{S}{K_S + S}\right) \qquad (2.6)$$

The Differential Evolution algorithm was performed ten times for each set of estimated parameters, with population size 20, 300 iterations, disturbance rate 0.8 and crossing probability 0.8.

The Ddaspk.f code (Petzold *et al.*, 2000) was utilized to solve the sensitivity (*se*) equations given by Eq. 2.7, where $y \in \mathrm{IR}^n$ and $b \in \mathrm{IR}^n{}_b$, for relative and absolute error tolerances equal to 10^{-6}.

$$F(t, y, y', b) = 0 \qquad \frac{\partial F}{\partial y}se_i + \frac{\partial F}{\partial y'}se_i' + \frac{\partial F}{\partial b_i} = 0, i = 1, \ldots, n_b \qquad se_i = \frac{dy}{db_i} \qquad (2.7)$$

The correlation between the model parameters was carried out as proposed by Sanz and Voss (2006), through association of parametric sensitivity and statistical parameters correlation and covariance (Eq. 2.8).

$$cor(b_i, b_J) = \frac{cov(b)_{iJ}}{[cov(b)_{ii}\, cov(b)_{JJ}]^{1/2}} \qquad cov(b) = \sigma^2 (se^T \omega se)^{-1} \qquad (2.8)$$

where σ^2 is the variance of errors in observations and ω is the matrix of weights.

3 Results and Discussion

The Table 3.1 presents the experimental results for cell yield (y_{xs}), ethanol yield (y_{ps}), ethanol productivity (Q_p) and final product concentration (p_f) for three different feeding rates F (L/h), also considering the effect of sucrose concentration (s_F) of the feeding flow.

Table 3.1 Experimental results: yields, productivity and final ethanol concentration

F (L/h)	1.166			0.872			0.670		
s_F (g/L)	218.4	245	277	218	245	285	217	241.4	285
y_{xs} (g/g)	0.007	0.018	0.020	0.026	0.027	0.018	0.024	0.021	0.018
y_{ps} (g/g)	0.415	0.415	0.408	0.450	0.431	0.404	0.445	0.418	0.413
Q_p(g/Lh)	4.8	4.9	4.6	6.2	5.1	4.38	5.3	4.5	4.8
p_f (g/L)	74.3	81.8	89.2	77.4	84.0	89.2	77.6	81.2	91.5

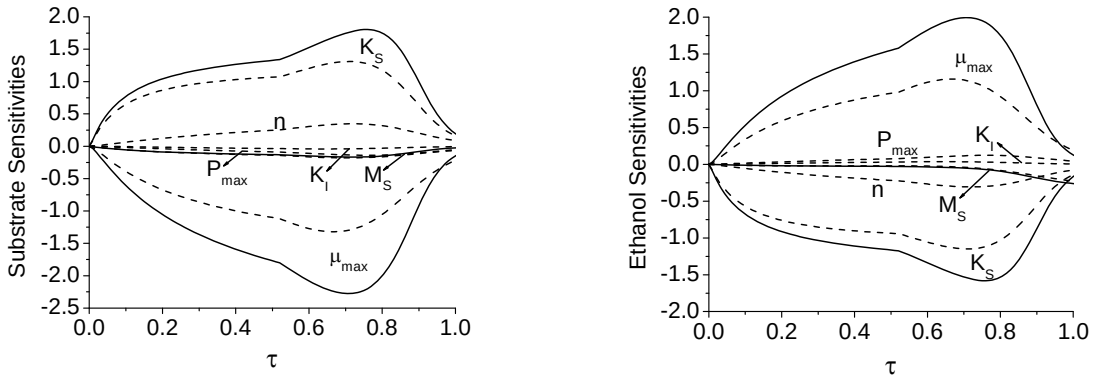
The increase of s_F resulted in increase of p_f without noticeable cellular growth. Considering the variations of the feeding rate for $s_F \approx 218$, $s_F \approx 245$ g/L and $s_F \approx 285$ g/L, the feeding flows F ≈ 0.872, 0.872 L/h e 0.670 L/h, respectively, supplied higher productivities and ethanol yields. The ethanol yields did not diminish linearly with feeding rate and the increase of feeding velocity resulted in smaller fermentation time, unlike the results obtained by Andrietta *et al.* (2003) which considered higher values of F and s_F in the range 230 - 254.8 g/L.

The Table 3.2 shows the dimensionless estimated parameters of kinetic models of Tosetto (Eq. 2.5) and of Monod (Eq.2.6) with respective Objective Function (OF) values.

Table 3.2 Estimated Dimensionless Parameters of Tosetto and Monod Kinetic Models

Parameter values	Tosetto Model	Monod Model
μ_{max}	0.3031	0.1971
K_S	0.08550	0.04764
K_i	1.166	------
P_{max}	0.8007	------
N	0.1832	------
M_S	0.03508	0.06038
OF	0.020946	0.025992

The parametric sensitivity profiles for $s_F \approx 241.4$ g/L can be seen in Fig. 3.1. The sensitivity profiles of cell concentration are similar to the ethanol concentration but with a smaller range of variation of the sensitivities, between -0.112 and 0.141. The parameters μ_{max} and K_S present the highest sensitivities. The sensitivity of the inhibition term power (n) is more evident at final time while for the cellular maintenance constant (M_S) it arises when sucrose concentration diminished reflecting the need of more nutrients by the cells. The sensitivity for P_{max} was relatively small along the time, being more significant when the ethanol concentration was more accentuated. The sensitivity of cellular growth inhibition constant by substrate (K_i) was the less significant. This sensitivity analysis indicates that a classical Monod model may accurately predict the kinetic of fermentation considering these operation conditions.



(a) (b)

Figure 3.1 (a) Sucrose and (b) ethanol concentration sensitivity profiles for s_F = 241,4 g/L regarding the parameters of the (---) Tosetto (2002) and (—) Monod models.

The correlations between the parameters of the Tosetto model are shown in Tab. 3.3 for s_F = 241.4 g/L. The majority of the parameter pairs exhibit high correlations. The parameters μ_{max} and K_S in Fig. 3.1, for example, presented similar profiles and opposite sign for all the variables S, X and P and model types indicating a positive correlation, while K_S and n presented similar profiles and equal sign indicating a negative correlation.

Table 3.3 Tosetto (2002) model parameter pair correlations for s_F = 241.4 g/L.

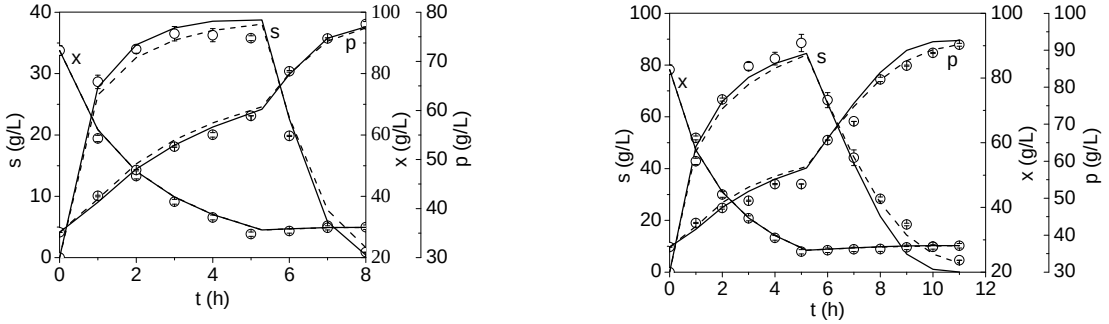
S	μ_{max}	K_S	K_i	P_{max}	n	M_s
μ_{max}	1.0	0.99	-0.99	-0.95	0.98	-0.99
K_S		1.0	0.97	0.94	-0.97	0.98
K_i			1.0	-0.95	0.98	-0.98
P_{max}				1.0	0.99	-0.98
N					1.0	0.99
M_s						1.0

X	μ_{max}	K_S	K_i	P_{max}	n	M_s
μ_{max}	1.0	0.99	-0.99	-0.95	0.98	0.45
K_S		1.0	0.97	0.94	-0.97	-0.44
K_i			1.0	-0.95	0.98	0.42
P_{max}				1.0	0.99	0.62
n					1.0	-0.53
M_s						1.0

P	μ_{max}	K_S	K_i	P_{max}	n	M_s
μ_{max}	1.0	0.99	-0.99	-0.95	0.98	0.45
K_S		1.0	0.97	0.94	-0.97	-0.44
K_i			1.0	-0.95	0.98	0.42
P_{max}				1.0	0.99	0.62
n					1.0	-0.53
M_s						1.0

The parameter pairs μ_{max}, K_S, K_i, P_{max} and n with M_S exhibit low correlations for the ethanol and cell concentrations and high correlations for the sucrose concentration for both models. This analysis confirms the behavior of previous sensitivity profiles where the pair [μ_{max}; M_S], for example, exhibit different profiles for P and similar profiles for S due to the low and high correlation, respectively.

The Figure 3.2 exhibits experimental and simulated results using the kinetic models of Tosetto and Monod for $s_F \approx$ 217 and $s_F \approx$ 285 g/L, where moderate deviations are observed in the sucrose concentration profile for $s_F \approx$ 285 g/L.



(a) (b)

Figure 3.2 Sucrose, cell and ethanol concentration profiles for (a) s_F = 217 g/L and (b) s_F = 285 g/L with F=0.670 L/h (○) Experimental data. (---) Simulated with the Tosetto model. (—) Simulated with the Monod model.

The Figure 3.3 presents the experimental validation of the Monod model for s_F = 277 g/L and F = 1.166 L/h proving its good capacity of prediction.

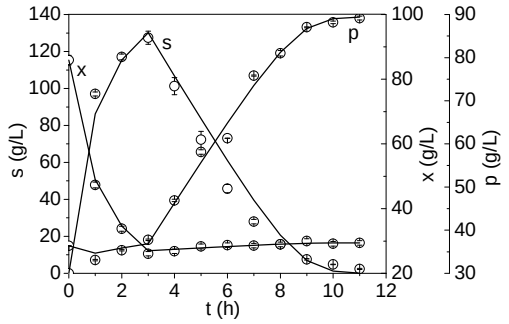


Figure 3.3 Sucrose, cell and ethanol concentration profiles for s_F = 277 g/L and F= 1.166 L/h (○) Experimental data. (—) Simulated with the Monod model.

4 Conclusions

The influence of the feeding rate and fed substrate concentration in the fed-batch alcoholic fermentation using sucrose and considering operational conditions representative of industrial conditions was shown. The influence of the parameters μ_{max} and K_S is the greatest amongst all the parameters considered while the influence of the cellular growth inhibition constant by substrate (K_i) is irrelevant. The cell concentration is less affected than product and substrate concentrations by parameters variations in the operation range considered. The parameters of Tosetto and Monod models were estimate using Differential Evolution. The analysis of correlation matrix between parameters, which exhibit high correlation for both models, confirmed the previous parametric sensitivity analysis. The Monod model was validated against experimental values with good results and due to its simplicity is appropriate for the modeling, simulation and optimization of the fed-batch process.

Keywords: Bioethanol production, lignocellulosic ethanol.
Topic: Integration of life sciences and engineering.

Abstract

This work presents a parametric analysis of total production costs of wheat straw-based ethanol for a hypothetical facility located in Mexico. Using the Net Present Value (NPV) method the ethanol price (USD/kg) was estimated as a function of plant size (feedstock flowrate) and feedstock cost, interest, investment period and equity percentage taking into consideration local economy conditions. The analysis is based on a standard process flowsheet incorporating novel technology for pretreatment and separation operations. Steady state mass balances calculations were made employing separation and reaction factors taken from "state-of the-art" literature for second generation biofuels. The resulting total costs are within competitive margins for this geographical region. For our base case, feedstock (34%) and production costs (28%) are the main contributors for the ethanol price. Therefore, process efficiency and technologies for diminishing production costs are alternatives worth exploring.

1 Introduction

First generation biofuels are currently in full commercial exploitation worldwide with production carried out using mature technologies. Following the steps of the US, the Mexican government has recently decided to incorporate in the short term biofuels as part of the transport fuel commercialized nationwide by the state-owned company Pemex. Therefore, it is highly probable that this substitution will be carried out with biofuel imports from large producer countries such as the US and Brazil and with the participation of players with large investing capacities and foreign technologies. Therefore, upper generation biofuels can be alternatives for local providers to participate in satisfying part of the transport fuel demand in a socially and environmentally sensible way. It is well accepted that raw matter contributes up to 40% to production costs and better process technology is currently is under development. Therefore, in order to study conditions for a feasible production in Mexico, this paper presents a parametric analysis of total production costs of wheat straw-based ethanol for a hypothetical facility. The wheat-straw was chosen as raw matter because the amounts and prices available in certain regions in Mexico as well as its secondary applications appear to be adequate for this exercise. Taking into consideration local economy conditions, the ethanol price (USD/kg) is estimated using the Net Present Value (NPV) method as a function of plant size (feedstock flowrate) and feedstock cost, interest, investment period and equity percentage as financial parameters. Results seem to indicate that production can be financially sound.

Plant related information (i.e. equipment size and process flows) is obtained from a steady state model of a modified process flowsheet (Aden et al. 2002) as discussed in section 2. Five main processing stages are considered: pretreatment, saccharification-fermentation, separation, services and cogeneration. Water treatment is considered part of the services stage due to its environmental relevance. The cogeneration stage includes both electricity and steam generation. Steady state mass balances were built

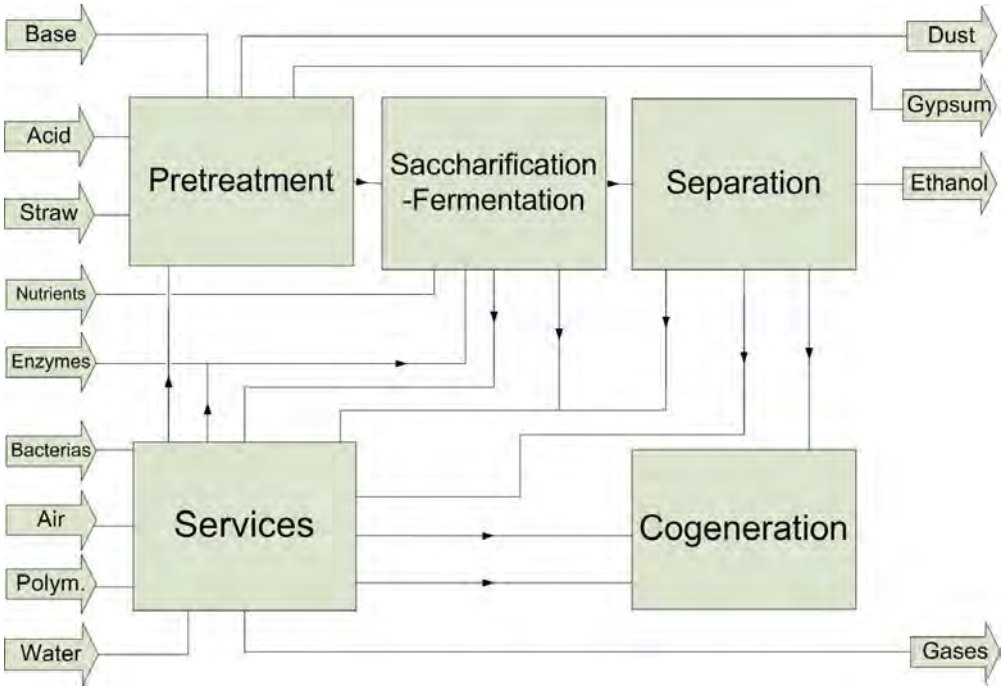

Figure 1: Process Flowsheet

for each stage. Section 3 presents the modelling strategy. Calculations for each stage were carried out employing separation and reaction factors taken from the "state-of the-art" literature (Aden et al. 2002), (Saha et al. 2005), (Thomsen et al. 2006) as well as from our own experience. Equipment cost calculations for each stage as well as total capital investment and total product costs were carried out using a standard conceptual design approach. Local economic conditions are taking into consideration. The ethanol price is estimated in section 4 employing the Net Present Value (NPV) technique. Using a base case of 200ton/day of wheat-straw, the resulting price is 0.75 USD/kg of ethanol. Feedstock (34%)and production costs (28%) are the main contributors, followed by equipment (21%) and other capital costs (18%). Therefore, improving process efficiency or technologies for diminishing production costs are alternatives worth exploring. The sensitivity of the model is explored for different feedstock flowrates and prices. Results show that if plant capacity is increased to manageable amounts, total costs are substantially reduced reaching feasible production costs. In the final part, the paper discusses crop and market conditions in Mexico and, in the light of these results, the relevance of urgently exploring other alternative sources for bioethanol production.

2 Plant Description

The process flowsheet is a modification of a standard model for ethanol production using corn stover (Aden et al. 2002). Five main processing stages are considered: pretreatment (size reduction and thermochemical treatment), saccharification and fermentation (polysaccharide's conversion to monosaccharide and ethanol production), separation (distillation to azeotropic point and molecular sieves), services (waste water treatment) and cogeneration (electricity and steam generation) (Aden et al. 2002), (Saha et al. 2005). Novel process technologies were incorporated for pretreatment and separation operations. A counterflow reaction system (Thomsen et al. 2006) is employed for the hydrolysis and molecular sieves for ethanol dehydration (Aden et al. 2002). The five main stages and the principal flowrates of the process are shown in Figure 1. Due to space limitations, flowsheets of each stage are not presented in this paper. Table 1 lists relevant process equipment separated by stages involved in this hypothetical ethanol plant.

3 Steady State Process Modelling

Steady state mass balances were built for each equipment. The model is written in terms of the total mass flowrates, component mass fractions and separation and reaction factors. Values for the last two types of parameters are taken from the "state-of the-art" literature (Aden et al. 2002), (Saha et al. 2005),(Thomsen et al. 2006). The complete model comprises 315 algebraic equations.

As an example of the model building strategy, the mass balance corresponding to the fermentation battery in the saccharification-fermentation stage is shown in Figure 2. Nomenclature is given in table 2. The mass balance comprises equations 1 to 5. Equation 1 represent the ethanol general balance in the ethanol fermenter (F201), $M_{207}X_{207ET}$ and $M_{106}X_{206ET}$ (the ethanol mass flow in streams 207 and 206) are the variables to solve. Equation 2 symbolizes the ethanol mass produced in F201 which is determined by equations 3 and 4. These equations correspond to the mass flowrates of glucose and pentose converted to ethanol and equation 5 describes the ethanol flowrate in the stream 206. $M_{202}X_{202ET}$ is the result of a previous balance not showed in this paper.

$$M_{202}X_{202ET} = M_{207}X_{207ET} + M_{206}X_{206ET} - r_{F201ET} \tag{1}$$

$$r_{F201ET} = \alpha + \beta \tag{2}$$

$$\alpha = \frac{2Z_{F201ETA}(M_{202}X_{202GL})PM_{ET}}{PM_{GL}} \tag{3}$$

$$\beta = \frac{5}{3}Z_{F201ETB}PM_{ET}(\frac{M202X_{202XY}}{PM_{XY}} + \frac{M_{202}X_{202AR}}{PM_{AR}}) \tag{4}$$

$$M_{206}X_{206ET} = Z_{F202033}(r_{201ET} + M_{202}X_{202ET}) \tag{5}$$

Variable	Description	Units	Factors	Description	Units

Table 2: Parameters corresponding to ethanol fermentor (F201)

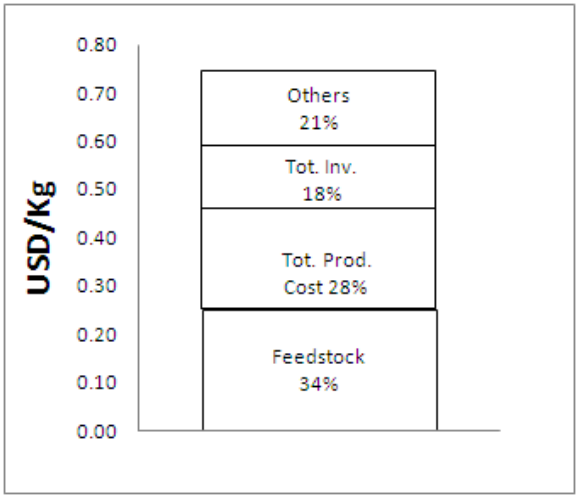

Figure 3: Contributions to ethanol cost

The mass balance results were employed to determined the equipment size of each stage (Seider et al. 2004) and a standard conceptual design procedure (Seider et al. 2004), (Douglas 1988) was employed to calculate, for each stage, the equipment costs and for the complete facility, total investment, total production costs, feedstock costs and annual cash flow using a base case (200 ton/day feedstock, 10 years life period, 9% discount rate, equity 30% and 0.07USD/kg for wheat straw price). The construction period was established in 2.5 years (Aden et al. 2002). The energy produced in the cogeneration stage was discounted to the utilities costs.

4 Net Present Value (NPV) Analysis

The NPV is the difference between the present values of the annual cash flows and the initial required investment. If $NPV = 0$ the discount rate i is understood as the return on investment (ROI). Equation 6 represents the standard NPV with ACF as the annual cash flow, n is the life period, I is the total investment, WC is the working capital. ACF, WC, I expresions were obtained based on Douglas (1988).

$$NPV = ACF\frac{(1+i)^n - 1}{(1+i)^n i} + \frac{WC}{(1+i)^n} - I \tag{6}$$

The NPV method and the base case mentioned previously were used to calculate the ethanol price. Best and worst case scenarios were established as boundaries for the sensitivity analysis. The price composition of the ethanol for the base case is shown in Figure 3. Total production cost (28%) and the raw material cost (34%) are the main contributions. Total investment (18%) and others (taxes, equity and general expenses) (21%) complete the ethanol price. Table 3 shows the resulting ethanol prices.

Sensitiviy analysis for ethanol price			
Factor	Best case	Base case	Worst case
Wheat straw flow rate (ton/day)	2,000	200	20
Wheat straw price (USD/kg)	0.03	0.07	0.07
Discount rate (%)	7	9	12
Life period (years)	15	10	5
Equity (%)	0	30	100
Ethanol price (USD/kg)	0.14	0.75	2.69

Table 3: Best and worst cases for ethanol price calculations

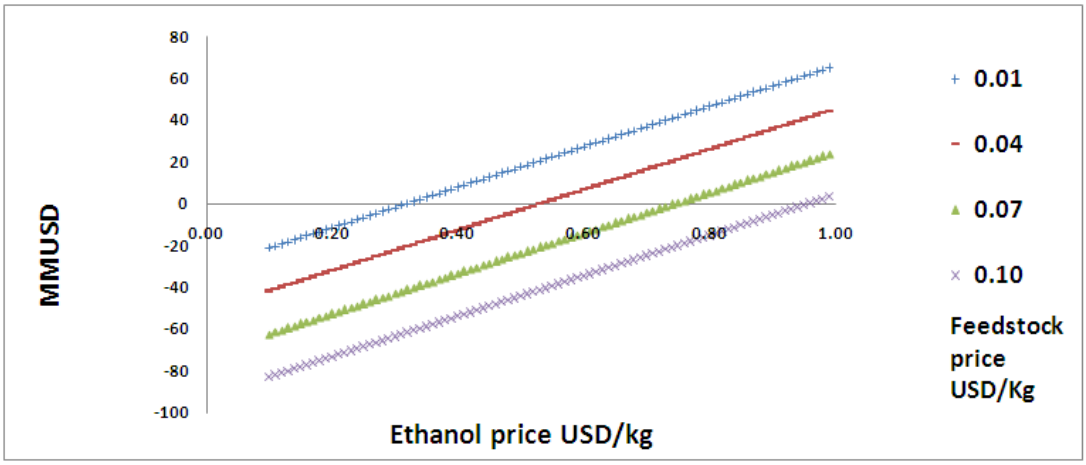

Figure 4: VPN vs Ethanol price for different feedstock prices

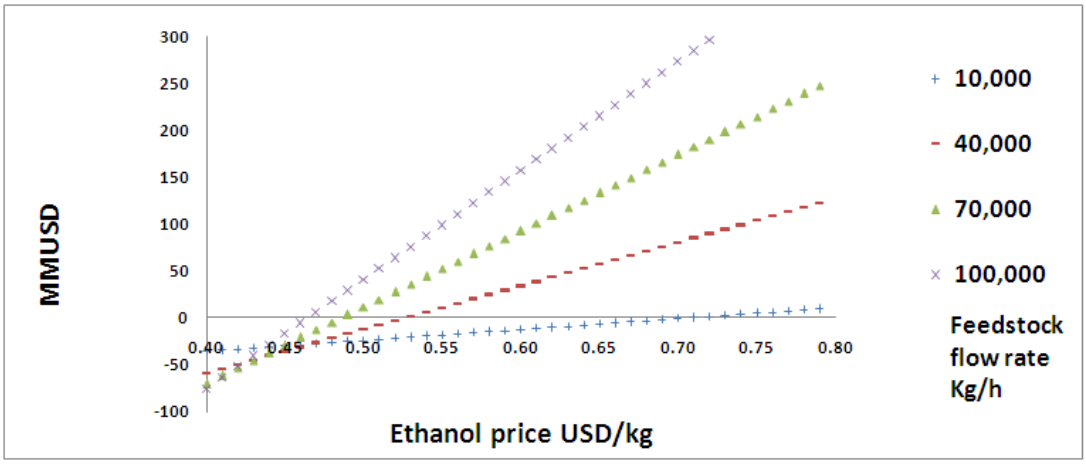

Figure 5: VPN vs Ethanol price for different feedstock flow rates

In this paper, results are presented for variations on feedstock price (Figure 4) and flowrate (Figure 5). The values for the rest of the independent variables were maintained as in the base case. Figure 4 indicates that the relation of feedstock price and the ethanol price is lineal. More interesting, figure 5 shows a negative exponential dependence of the ethanol price with the feedstock flowrate. This is because the feedstock flowrate is a function of the equipment price equations that have a logarithmic form. Therefore, the feedstock flowrate could be increased (e.g. 4 times the base case flowrate) in order to be in a "good design zone" .

5 Conclusion

The results obtained in this exercise are similar in order of magnitude to others previously published using different second generation feedstocks (Aden et al. 2002). Since the main contributors to ethanol price are feedstock and total production costs, alternative sources of lignocellulosic materials as well as process efficiency and new technologies are important aspects worth exploring. Results show that competitive ethanol prices can be achieved with plant sizes and feedstock amounts suitable to be handled within the local economy. However, it is important to take into consideration possible pressures originated from the large installed production capacity of first generation ethanol and financial factors in other countries as well as the lack of policies in Mexico regarding this matter. For instance, the US currently employs more than 10 % of its maize production (which represents three times the national maize consumption) to serve an industry with important tax exception programs and demanding to duplicate feedstock available for producing first generation ethanol. Moreover, Mexico is highly dependent on basic crops from foreign suppliers (30% and 50% of its maize and wheat consumption is imported) and maize and wheat stover are important sources of food for livestock. Thus, they must be cautiously employed for ethanol production.

Topic: Integration of life sciences & engineering

Abstract
Biopolymers are produced commonly by submerged fermentation and among those with high commercial value is xanthan gum. Acting as thickening, stabilizing excellent, suspension and emulsifying agent this gum possesses many advantages due to its superior rheological characteristics. Studies of process variables optimization and kinetic profile using sugar cane broth in the xanthan gum biosynthesis have not been reported by the literature. Due the mentioned relevance, this work was developed with the purpose of optimizing agitation speed and aeration level in the xanthan production using sugar cane broth diluted, as well as to evaluate the kinetic behavior in the optimum condition by Weiss and Ollis model. Therefore, the conversion and viscosity obtained were (0.607 $g.g^{-1}$) and (23,002 cP) using sucrose concentration (27.0 g/L), yeast extract (2.0 g/L), ammonium nitrate (0.8 g/L), 750 rpm, and 0.35 vvm.

1 - Introduction
Xanthan gum is a natural polysaccharide and an important industrial biopolymer, is classified as a ramified, anionic hetero-exopolysaccharide, and is produced by fermentation using the bacterium *Xanthomonas*. The main producers of xanthan are Merck, Kelco, and Pfizer in the United States; Rhône Poulenc, Mero-Rousselot-Santia, and Sanofi-Elf in France; Saidy Chemical in China; and Jungbunzlauer in Austria (García-Ochoa et al. 2000; Pradella, 2006). World production of xanthan gum is 30,000 tons/year (Skaracis et al. 2003; Pradella, 2006), while its consumption in the United States has an annual growth rate between 5-10% (Harcum et al., 1999). Xanthan has an actual market of approximately US$ 270 million, and is expected to reach US$ 400 million with a production of 80,000 tons/year in 2015 (Pradella, 2006). Xanthan production is usually modeled by unstructured models as described by Moraine and Rogovin (1971), De Vuyst et al. (1987) and Pons et al. (1990). García-Ochoa et al. (1995) and Letisse et al. (2003) have proposed and applied unstructured kinetic models describing biomass, carbon source, nitrogen source, and dissolved oxygen evolution. Rosalam and England (2006) in yours review to the xanthan gum production reported also the characteristics of the unstructured and structured kinetics models emphasizing the kinetics behavior has been described by García Ochoa et al. (1995) and Weiss and Ollis (1980) models. Since Brazil is a major producer of sugar cane, it is advantageous for researchers there to create new biotechnological processes using cane broth as the raw material for the production of xanthan gum. The purpose of this study was to optimize the process variables of sucrose, yeast extract, ammonium nitrate concentrations, agitation speed and aeration. Response surface methodology was used for optimization, and the kinetic parameters (μ_{max}, X^*, m, λ, α, and β) regarding the bioprocess were obtained by applying the unstructured kinetic model.

2 - Materials and methods

In previous studies, the nitrogen source was selected and a central composite design of sixteen experiments, defined three quantitative variables to represent the optimum composition of the medium inside of researched range: sucrose concentration (27.0 g/L), yeast extract (2.0 g/L) and ammonium nitrate (0.8 g/L). Na_2HPO_4 (2.5 g/L) and KH_2PO_4 (2.5 g/L) were also added in the medium as buffer agent. In the described conditions, a factorial project 3^2 was idealized with the objective of discovering the influence of the agitation speed (500, 750 and 1,000 rpm) and aeration (0.25; 0.5 and 0.75 vvm) in the process, once that their costs are considerable and happens directly in the final price of the product. Concisely, the adopted procedure consisted in the accomplishment of two different stages: the fermentative process and the recovery of the gum. The fermentations were carried out in a 2.0 L Biostat-B bioreactor by *Xanthomonas campestris pv. campestris* NRRL B-1459 at constant temperature and pH of 28 ± 1^oC and 7.5, respectively, for 24 hours. The working volume was 1.5 L. The monitored responses were: substrate conversion to product ($Y_{P/S}$) and gum viscosity in solution 1% using 0.75 s^{-1}. The sucrose, after acidic hydrolysis, was assayed by the enzymatic method using glucose-oxidase and the viscosities were measured by the Brookfield RVDVIII rheometer. The measurements of dissolved oxygen for determination of the Oxygen Transfer Coefficient (K_La) were done in the absence of the inoculum. The recovery and the purification of the polymeric were done as suggested by the literature. The fermented broth was diluted 1:1 with deionized water and centrifuged in a Beckman Coulter Avanti J-25 centrifuge at 18,900x*g* for 40 min to remove cells. The supernatant was filtered and treated with a saturated solution of KCl; the polymer was recovered by precipitation with ethanol (Ramírez et al., 1988). The unstructured kinetic model used in this investigation expresses the growth rate only as a function of the biomass, by utilization of the Verhulst-Pearl equation [Eq. (1)] and the Luedeking-Piret equations [Eqs. (2) and (3)] (Luedeking and Piret, 1959).

$$\frac{dX}{dt} = \mu_{max} X \left(1 - \frac{X}{X_{max}} \right) \quad (1)$$

$$\frac{dP}{dt} = m \frac{dX}{dt} + \lambda X \quad \text{where} \quad m = \frac{1}{Y_{X/P}} \quad (2)$$

$$-\frac{dS}{dt} = \alpha \frac{dX}{dt} + \beta X \quad \text{where} \quad \alpha = \frac{1}{Y_{X/S}} \quad (3)$$

The kinetic parameters ($\mu_{max.}$, $X_{max.}$, m, λ, α and β) of the Weiss and Ollis (1980) model were obtained by non-linear regression using a multiresponse algorithm.

3 - Results and discussion

Table 1 presents the obtained results for the factorial project 3^2 executed. In this way, in agreement with the response surface methodology (RSM), the agitation speed and the aeration of 750 rpm and 0.35 vvm produced experimentally the most expressive responses for the conversion (0.607 $g.g^{-1}$) and the viscosity (23,002 cP) inside of the investigated optimization region. These results showing that the process costs are smaller when compared to the agitation speed (800 rpm) and aeration (0.5 vvm) fixed in the first central composite design for the sixteen assays. All of the experiments were accomplished in duplicate and the optimized point was confirmed.

Table 1 – Effect of the independent variables, agitation speed and aeration, in the responses $Y_{P/S}$ and viscosity.

Runs	Agitation speed [rpm] X_1	Aeration [vvm] X_2	K_La [h^{-1}]	$Y_{P/S}$ [$g.g^{-1}$]	Viscosity 0.75 s^{-1} [cP]
1	500	0.25	24.978	0.486	18,200
2	500	0.50	30.966	0.479	19,000
3	500	0.75	41.034	0.435	18,000
4	750	0.25	40.614	0.600	23,470
5	750	0.50	58.65	0.633	24,000
6	750	0.75	66.66	0.577	23,400
7	1,000	0.25	51.858	0.615	22,900
8	1,000	0.50	69.678	0.607	23,100
9	1,000	0.75	78.558	0.544	21,680
10	750	0.50	57.921	0.637	24,300
11	750	0.50	59.235	0.641	24,500

Experiments 5, 10 and 11 were done with the values of the variables set at the central point (Table 1). The central point represents the best conditions obtained for the responses, $Y_{P/S}$ (0.641 $g.g^{-1}$), and viscosity of the gum solution at 1% concentration (24,500.0 cP). Statistical analysis using the response surface technique confirmed that the maximum point was close to the central point. For statistical analysis of the responses, the parameters with significance levels larger than 10%, using a t-Student hypothesis test, were not considered relevant.

Figure 1 represents the contour plots for X_1 and X_2 considering $Y_{P/S}$ (A), and viscosity (B), while, Figure 2 illustrates the response surface for the Oxygen Transfer Coefficient. Figure 1 is very important because shows the optimum range of operation (black area) for agitation speed and aeration rate, furthermore, it is evident from these figures that we can find a desirable combination of X_1 and X_2 for increased the xanthan production and viscosity of the gum solution. Equations 4, 5, and 6 refer to the effects of the isolated variables X_1, and X_2 and the quadratic interactions effects that compose the adjusted statistical models.

The optimized conversion $Y_{P/S}$ calculated from the Equation 4 was 0.634 $g.g^{-1}$ when the maximum point (750 rpm, and 0.35 vvm) was substituted, while, the optimized viscosity and K_La calculated from the Equations (5, 6) were 24,117 cP and 49.736 h^{-1}, respectively.

$$Y_{P/S} = 0.632 + 0.0611X_1 - 0.0805(X_1)^2 - 0.0241X_2 - 0.0352(X_2)^2 \qquad (r^2) = 0.98 \qquad (4)$$

$$Y_{Viscosity} = 24{,}272 + 2{,}080X_1 - 3{,}229(X_1)^2 - 248X_2 - 844(X_2)^2 - 255(X_1X_2) \qquad (r^2) = 0.99 \qquad (5)$$

$$Y_{KLa} = 56.616 + 17.186X_1 - 7.104(X_1)^2 + 11.467X_2 \qquad (r^2) = 0.97 \qquad (6)$$

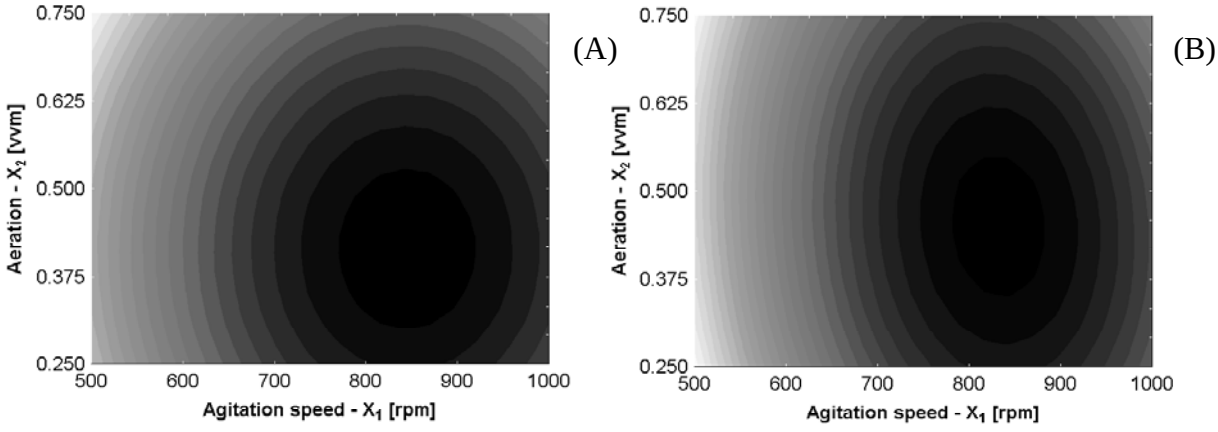

Figure 1 – Contour plot considering X_1 (agitation speed) and X_2 (aeration): (A) $Y_{P/S}$ response, (B) Viscosity response. It was found for region of the optimum (black area), maximum conversion and viscosity of 0.61 $g.g^{-1}$ and 24,000 cP, respectively.

Figure 2 shows the variation of Oxygen Transfer Coefficient for different combinations of X_1 and X_2. It should be noted that higher K_La can be obtained by increasing the agitation speed and aeration. A second ordered polynomial model was fitted and optimum conditions were estimated (Equation 6). Furthermore, the magnitudes of coefficients indicated that the agitation has more positive linear influence than the aeration.

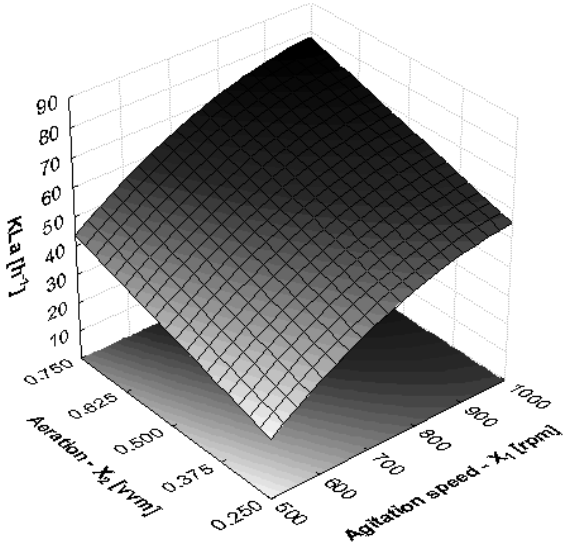

Figure 2 – 3D Plots of response surface optimization experiment results: the effect of agitation speed and aeration on the Oxygen Transfer Coefficient (K_La).

Figure 3 represents a typical correlation graph of the amount of oxygen dissolved with the time for different agitation speeds and aeration rates. The angular coefficient of the straight lines gives the K_La value for each assay.

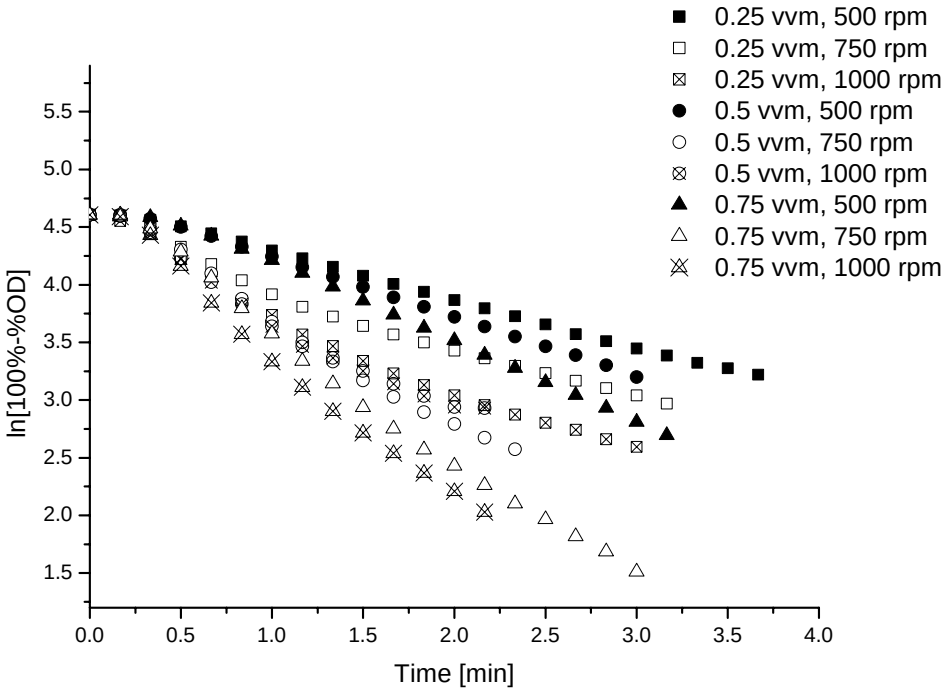

Figure 3 – Oxygen Transfer in function of the aeration rate (0.25, 0.50, 0.75 vvm) and agitation speed (500, 750, 1,000 rpm).

Table 2 shows the kinetic parameters determined in the optimized conditions of aeration and agitation speed in the factorial project 3^2. The variability between the studies can be explained hypothetically by differences in correlated factors, including the strain selected,

C/N relationship, nitrogen source, agitation speed, aeration rate, pH control in the medium, and the use of complex mediums, such as sugar cane broth. In addition, it is difficult to characterize complex fermentation processes.

Table 2 – Comparison of kinetic constant values from modeling and the literature.

Parameters	Assay in the optimized condition	Weiss & Ollis (1980)	Pinches & Pallent (1986)	García-Ochoa et al. (1990)	Serrano-Carreón et al. (1998)	Letisse et al. (2003)
μ_{max} [h^{-1}]	0.429 ± 0.037	0.152	0.29	0.110	0.25	0.38
X_{max} [g/L]	2.665 ± 0.094	2.450	2.15	1.790	4.42	3.30
α [gS/gX]	0.334 ± 0.091	2.00	1.24	14.286	3.03	3.23
β [gS(gX h)$^{-1}$]	0.529 ± 0.067	0.284	0.24	0.120	0.26	0.36
m [gP/gX]	0.120 ± 0.055	1.830	0.47	10.00	2.00	0.50
λ [gP(gX h)$^{-1}$]	0.342 ± 0.041	0.155	0.13	0.003	0.25	0.23

The kinetic study was accomplished for the point found experimentally by design. A fourth order Runge-Kutta algorithm was coupled to the non-linear regression method to derive the solutions for the differential equations 1, 2, and 3. The kinetic parameter values determined in this study were within the ranges reported in the literature, as shown in Table 2. Except α (associated growth terms), the others parameters were closest to those cited by Letisse et al. (2003). In the Figure 4, when the experimental data are compared to the quantitative responses predicted by the Weiss and Ollis model, there is a high degree of correspondence suggesting a good model fit.

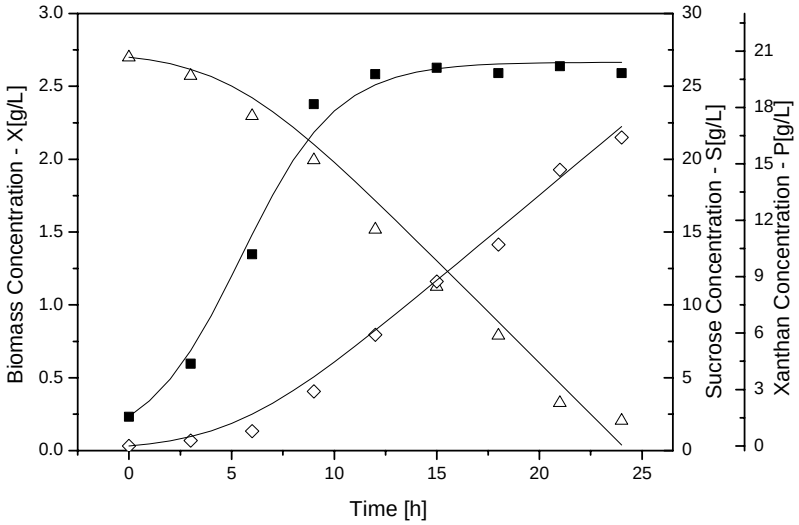

Figure 4 – Change in the concentration of microbial biomass (■), sucrose (Δ), and xanthan gum (◇). Symbols represent the experimental results; lines represent the Verhulst-Pearl (V-P) and Luedeking-Piret (L-P) kinetic model data.

4 - Conclusion

Therefore, this paper goal the optimization of the process variables in the xanthan gum biosynthesis from the sugar cane broth. The adjusted statistical models for the studied responses represented the experimental data accurately. The results show that higher levels of xanthan gum can be produced on the central point and optimum region of operation when the variables evaluated were agitation speed and aeration. Regarding the kinetic study, the Weiss and Ollis model adjusted the experimental data satisfactorily for the cellular growth, the substrate consumption and the product formation.

Keywords: Xylanase, Wheat straw, Wheat bran, Autohydrolysis liquor, Fermentation
Topic: Multi-scale and/or multi-disciplinary approach to process-product innovation

Abstract

Agro-industrial residues are lignocellulosic materials with a high content of cellulose, hemicellulose and lignin. If such residues can be produced in bioprocesses (e.g. xylanase production) there is an attractive possibility of their integral use in biotechnological processes. In general, xylanase biosynthesis is induced by its substrate – xylan, but the high xylan content of some wastes such as corn cobs and wheat bran makes them an accessible and cheap source of inducers. Another alternative to improve the xylanase production, which is the main goal of this work, is the treatment of lignocellulosic materials in autohydrolysis processes which, under optimized conditions, lead to the solubilization of hemicelluloses (liquid phase, liquor) that may be favorable to xylanase production. The inclusion of these components in the nutrient medium composition can be a strategy to optimize the microbial xylanase biosynthesis. The best conditions for xylanase production were observed when the microorganism was cultivated in birchwood xylan for 6 days; however, satisfactory results were obtained using a combination of 1% wheat bran with 2% or 10% autohydrolysis liquor, for 5 days fermentation, once the xylanase production was around 86-87% of production with xylan. Besides, the obtained production with 100% wheat straw autohydrolysis liquor was also interesting, once after 7 days of cultivation, the xylanase production was higher than the ones obtained with wheat bran or by the combination of wheat bran and liquor.

1 Introduction

The hemicelluloses are a large group of high molecular polysaccharides, insoluble in water but soluble in alkaline solutions. These polysaccharides are associated with cellulose and lignin and play an important structurally-supportive role in building up of plant cell walls (Nakamura, 2003). The composition of hemicelluloses, includes branched heteropolymers of pentoses (xylose, arabinose), hexoses (mannose, galactose, glucose), and uronic acids. Xylan is the major constituent of hemicellulose and the second most abundant renewable resource with a high potential for degradation to useful end-products. Microbial xylanases (1,4-β-D-xylan xylanohydrolase, EC 3.2.1.8) are the preferred catalysts for xylan hydrolysis due to their high specificity, negligible substrate loss and side product generation. During the last decades, xylanases have attracted considerable research interest because of their potential industrial applications (Chen et al., 1997; Yuan et al., 2004).

* Corresponding author. Tel +351-253-604406. E-mail: jateixeira@deb.uminho.pt

The enzyme hydrolysis of xylan lies in the basis of its utilization as an energy source in animal feed or in different biotechnological processes (Coughlan and Hazlewood, 1993; Kulkarni et al., 1999; Subramanyan and Prema, 2002). The partial enzyme hydrolysis of xylan changes its physical and chemical properties, which concerns the quality of different products of the food and flavour industry. Xylanase finds applications in fruit juices and wines clarifying (Colins et al., 2005; Coughlan and Hazlewood, 1993). In brewing, xylanase is applied in filtering improvement (Yin et al., 2005). The utilization of xylanase in bread-making significantly improves the desirable texture, loaf volume and shelf life of bread (Courtin and Delcour, 2002). Xylanase enzyme preparations are also widely used in bio-bleaching in paper industry. They facilitate the delignification of the plant pulp in the production of high-quality paper. In that way, the chlorine-containing bleaching agents, that are a serious ecological problem, can be reduced (Gupta et al., 2000).

The industrial production of xylanase preparations is based on a microbial biosynthesis. Most often industrial xylanase producing strains moulds of the species *Aspergillus sp.* and *Trichoderma sp.*, as well as bacterial strains of the species *Bacillus sp.*, are used. There are two possibilities for cultivation of microbial enzyme producing strains: solid-state and submerged cultivation (Gawande and Kamat, 1999). At the present moment, the submerged cultivation is more widely used, allowing a higher degree of processes intensification and a better level of automation. Xylanases from moulds are extracellular, inducible enzymes. That determines the great significance of nutrient medium selection. The xylanase biosynthesis is induced by its substrate – xylan (Subramanyan and Prema, 2002; Kulkarni et al., 1999). The high xylan content of some of the wastes such as corn cobs and wheat bran makes them an accessible and cheap source of inducers. Annually about seven million tonnes of wastes are deposited from the member-countries of the EU, in the form of corn and wheat bran (Bonnin et al., 2001). The inclusion of these components in the nutrient media composition is the main strategy in microbial xylanase biosynthesis (Davidov and Atev, 1996).

Besides, treatments of lignocellulosic materials in aqueous media (autohydrolysis or hydrothermal treatments) under optimized conditions lead to the solubilisation of hemicelluloses, leaving a solid phase enriched in both cellulose and lignin (Garrote et al., 1999). This solid phase can be subjected to further processing to obtain a variety of commercial products, e.g. enzymatic hydrolysis and further fermentation of hydrolyzates (Rivas et al., 2004), allowing an integrated use of the raw material; in turn, the liquid phase can be used to optimize the microbial biosynthesis of enzymes. Thus, in this work, the performance of wheat straw autohydrolysis liquor as adjunct in medium containing wheat bran for xylanase production in submerged cultivation of the strain *Aspergillus terricola* was evaluated.

2 Materials and methods

Material

Wheat residues (wheat bran and wheat straw) were kindly supplied by a local farmer (Portugal). The wheat bran stored at room temperature and the wheat straw (material for autohydrolysis in this work), after being dried at 40 ºC in an oven for 12 h, was cut into small pieces (1-3 cm), milled in a knives mill to pass through a 0.4 mm screen (for chemical composition) and 1.0 mm (for hydrothermal pre-treatments).

Liquor obtaining: wheat straw autohydrolysis treatment

Wheat straw samples and water were mixed in a closed and pressurized vessel in order to obtain a liquid/solid ratio of 10:1 w/w. The system was heated to 200 ºC during 30 min. The liquid phase or liquor (hemicelluloses rich fraction) was separated from the solids by filtration. The hemicelluloses were then precipitated with three volumes of 95% ethanol (20 °C, 24 h) and dried for yield determination (4.9%), or used directly as liquid substrate.

Microorganism and fermentation runs

The microorganism used in this work was the fungal strain *Aspergillus terricola* Marchal. This fungus was colleted on *campus* Ribeirão Preto of São Paulo University (Brazil), in an area near to laboratory of Microbioly and Cellular Biology, on Biology department of Faculty of Philosophy, Sciences and Letters for Michele Michelin, and identified by the fungal collection of Pernambuco Federal University (Brazil). This fungus was maintained at 30 °C, on slants of solid PDA media (Difco). Conidia from 7- day-old cultures, with cell concentration of 2×10^7 cells.mL^{-1}, were inoculated into 250 ml Erlenmeyer flasks containing 50 ml of the liquid medium described by Vogel et al. (Vogel et al., 1964), pH 6.0, containing the carbon source: 1% (w/v) birchwood xylan; 1% (w/v) wheat bran; 100% (v/v) wheat straw autohydrolysis liquor; combination of 1% (w/v) wheat bran and 2% (v/v) wheat straw autohydrolysis liquor; and combination of 1% (w/v) wheat bran and 10% (v/v) wheat straw autohydrolysis liquor. The cultures were incubated at 30 °C, for 100 rpm, a maximum of seven days. During fermentations, samples were taken in specified intervals and both the mycelia and residues were removed by centrifugation at 10000 g for 15 minutes. The filtrates were used as the source of crude extra-cellular xylanase and β-xylosidase.

Figure 1 shows a scheme for the production of wheat straw autohydrolysis liquor, extraction of hemicelluloses from ground wheat straw.

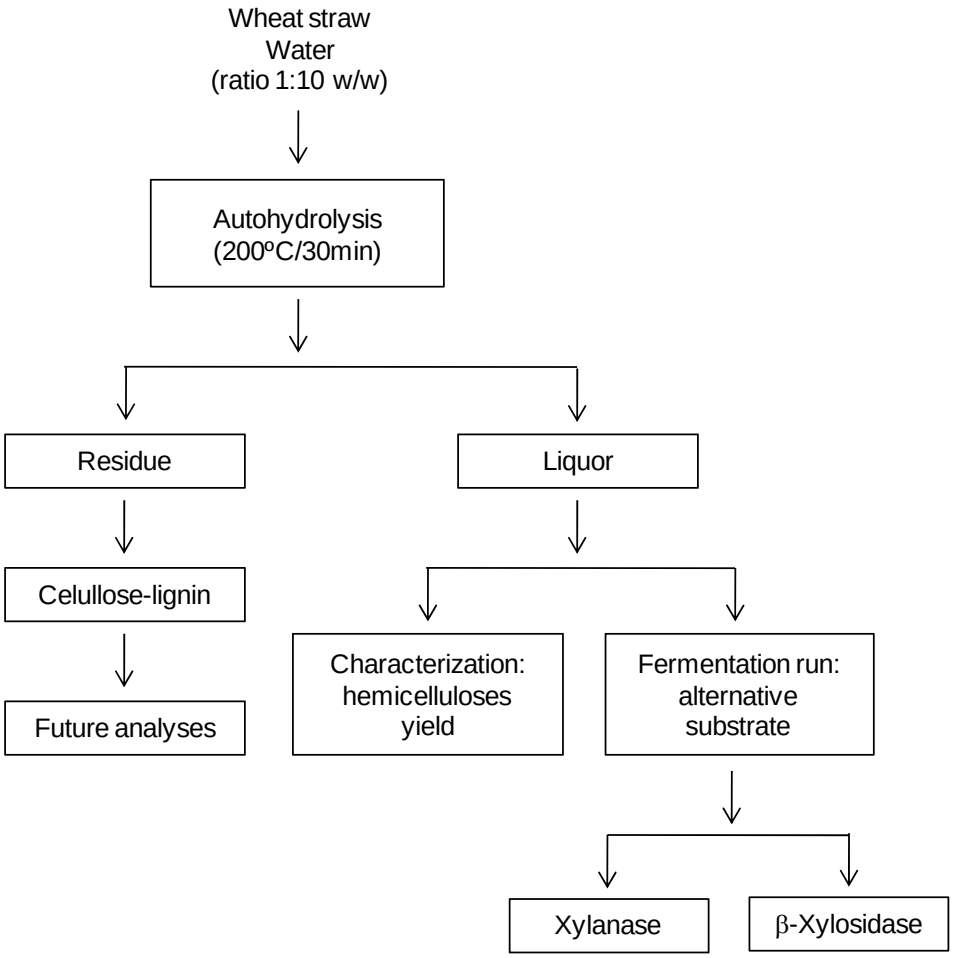

Figure 1. Scheme for extraction of hemicelluloses from ground wheat straw

Activity determinations

Xylanase activity was assayed using 1% (w/v) of birchwood xylan (Sigma, St. Louis, MO, USA) as substrate. Reaction mixtures contained 0.2 ml enzyme and 0.2 ml 1% xylan solution in citrate-phosphate buffer, pH 6.0 (Vilela et al.,1973). The mixture was incubated at 60ºC, and after predetermined periods the released reducing sugars were estimated with 3,5-dinitrosalicylic acid (DNS), using xylose as standard (Miller, 1959). One unit of xylanase activity was defined as the amount of enzyme that released 1 μmol product per minute under the conditions of the assay.

β-Xylosidase activity was assayed using 0.25% (w/v) of *p*-nitrophenyl-β-D-xylopyranoside (PNP-xyl) as substrate. Reaction mixtures containing 0.2 ml enzyme, 0.15 ml citrate-phosphate buffer, pH 4.5 (Vilela et al., 1973) and 0.05 ml 0.25% PNP-xyl in distilled water. The mixture was incubated at 70ºC, and after predetermined periods the released *p*-nitrophenolate were estimated with saturated sodium tetraborate solution, using *p*-nitrophenol as standard. One unit of β-xylosidase was defined as the amount of enzyme that released 1 μmol of product per minute under the conditions of the assay.

3 Results and discussion

Several fungal industrial production processes use complex media, consisting of agricultural byproducts as corn steep liquor, peanut flour, sugar beat molasses, pharma medium, etc. These media are inexpensive and yield much higher productivity than synthetic ones. The particular polymer (cellulose, hemicellulose, starch, protein), which often forms a suspension in the complex cultivation medium, serves as an inducer for the formation of hydrolyzing enzymes. This is the case for the production of xylanase, which is induced by xylan, an integral component of wheat bran (Adolph et al., 1996).

In our work, and according to Figure 2, the best conditions for xylanase production were observed when the microorganism was cultivated in birchwood xylan during 6 days of incubation. However, when on industrial level, this substrate become impracticable because of its high cost. In this context, the use of residues as well as its subproducts become very atractive. Besides, the use of wheat bran as inducer for xylanase production was very good (around 82% of production verified with xylan). However, the use of combinations of wheat bran and wheat straw autohydrolysis liquor, as well as only autohydrolysis liquor was superior that obtained with only wheat bran, once that with 5 days of fermentation the production obtained with combinations of wheat straw autohydrolysis liquor was of 86-87% when compared with birchwood xylan; and the prodction of xylanolytic enzymes using 100% liquor as adjunt on fermentation during seven days was 88% of production obtained with xylan

The fermentation process was conducted during 7 days; however in this period the xylanase production was still being induced by the wheat straw autohydrolysis liquor. Thus, with this result two conclusions were taken: (i) xylanase production can be improved in periods longer than 7 days when using autohydrolysis liquor; and (ii) it is possible that the induction of xylanases using wheat straw autohydrolysis liquor, produced under different conditions of time and temperature, can be more favorable for xylanase production, once the enzymic production started with 5 days of incubation (Figure 2). These results suggest the presence of short xylooligosaccharides on wheat straw autohydrolysis liquor, being that the use of wheat straw autohydrolysis liquor that posses xylooligosaccharides higher perhaps can be more favorable to xylanase induction.

Thus, by temperature control and reaction time it is possible to influence characteristics of the xylo-oligosaccharides such as the acetyl content and the molar mass distribution (Nabarlatz et al., 2004, 2005), but the nature of the raw material has also a significant role.

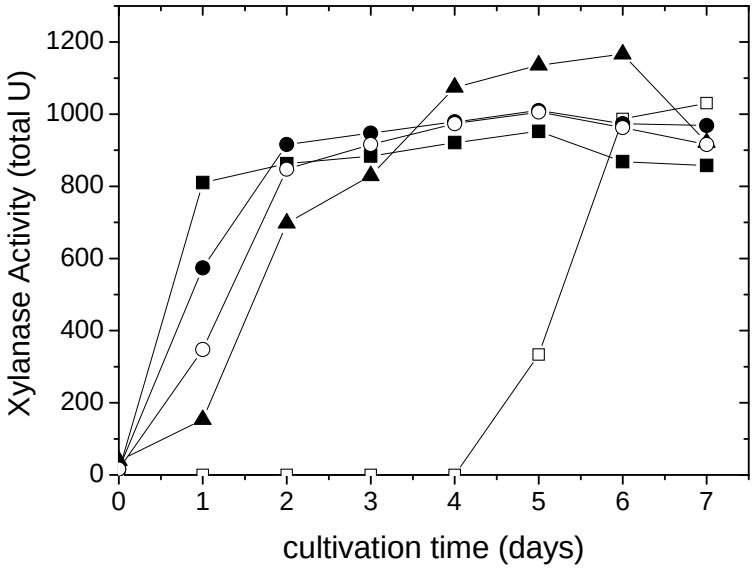

Figure 2. Performance of *A. ochraceus* during fermentation for xylanase production using different carbon sources: 1% (w/v) birchwood xylan (-▲-), 1% (w/v) wheat bran (-■-), 100% (v/v) wheat straw autohydrolysis liquor (-□-), combination of 1% (w/v) wheat bran and 2% (v/v) wheat straw autohydrolysis liquor (-●-), and combination of 1% (w/v) wheat bran and 10% (v/v) wheat straw autohydrolysis liquor (-○-)as adjunct. The microorganism was cultivated at 30ºC, 100 rpm.

4 Conclusion

Wheat straw autohydrolysis liquor showed to be promising as adjunct in xylanase and β-xylosidase production processes by filamentous fungi. This suggests that studies of liquor preparation under more convenient times and temperatures can result in a liquor more appropriated to the production of xylanolytic enzymes. This process is very attractive due to the use of residues (such as wheat straw) and also due to its low cost, therefore adding value to final product.

Albert Einstein, 500, Post Code: 6066, Zip Code: 13081-970, Barão Geraldo,Campinas, SP, Brazil.

Key-words: starch, manioc roots, alcohol, kinetic model.
Topic: Integration of life sciences & engineering

Abstract: This work shows optimal conditions of using the amylases from *A. niger* in starch hydrolysis and alcohol production from manioc root starch. Bioreactors contained manioc starch at 10 and 20 g/L of concentration on temperatures of 35 and 55°C, at pH 4.8 were made for evaluation of effects of starch concentration and temperature on hydrolysis yield. New models for starch hydrolysis kinetic were fitted; for substratum dependence ([S]) to the hydrolysis time (t) and hydrolysis rate (V) dependence with the substratum concentration ([S]). Results showed that exponential models fitted more than other models. Fitting model were $[S] = e^{-kt}$ and $V = e^{\frac{V_{max}}{K_M}[S]}$, while k, V_{max} and K_M are kinetic constant, maxim velocity and Michaelis-Menten constant, respectively. These models possible to simulate the hydrolysis process by amylases and its scale-up of this process. On starch hydrolysis, it perceived that in optimal condition the mean yield got 70%. After fermentation an alcohol yield above of 45% was gotten (the theoretical is 51.1%). This work showed as to obtain alcohol of manioc root starch, as alternative to the substitution of the sugar-cane juice in alcohol production.

1 Introduction

The hydrolysis of starch to products with low molecular weight, catalyzed by amylases, is the most important commercial enzyme process. The hydrolyzed products are widely applied in food, paper, and textile industries (Konzula and Liakopoulon-Kyriakides, 2004). Because of the increasing demand for these enzymes in various industries, there is enormous interest in developing enzymes with better properties, such as raw starch degrading amylases suitable for industrial applications and their cost-effective production techniques.

Being a renewable fuel and a lower pollutant when compared with petroleum fuels, ethylic alcohol is a combustible car fuel widely used in Brazil, and is desired by various countries. Recently, a search for new energetic sources was unleashed after the pronounced governing of various countries on a possible energetic crisis. At present, Brazil is in search of methods that will increase the ethanol offer by production of the combustible alcohol (Oliveira and Vasconcelos, 2006). Starch, the main reserve carbohydrate of several crops, is highly abundant in nature and can be easily extracted with high purity and at low cost (Cereda et al., 2001). Recently, a search for new energetic sources was unleashed after the pronounced governing of various countries on a possible energetic crisis.

Thus, it shows the optimal conditions to produce fermentable syrup from manioc starch and as a potential substitute to sugarcane in alcohol production. The food industry is using starch for a long time as ingredient because of its functional properties.

Modeling and optimization of processes are good tools for knowing and reducing of costs of industrial processes. Thus, in this work aimed to make a new model to simulate the hydrolysis processes by amylases from *Aspergillus niger* for alcohol production from manioc root starch

2 Material and Methods

2.1 Making of Bioreactors

Bioreactors contained 10 and 20 g/L of Starch concentration, at pH 4.8 and temperatures of 35 and 55°C were made, for evaluation of effects of starch concentration and temperature on hydrolysis yield. Total volumes of bioreactors were of 25 mL and they are heated on water bather. After temperature equilibrium had got in bioreactor, 0.5 mL of α-amylases (Forilase NTL®) from *Aspergillus niger* provided by Cognis (São Paulo, Brazil) were added. Total protein contents of Forilase NTL® measured by Bradford (1976) was of 11,214 mg/mL, so, total protein content on bioreactor, $[E]_0$ was of 0.2243 mg/mL or 0.2243 g/L. Glucose concentration released was measured time to time by DNS method (Miller, 1959).

2.2 Hydrolysis scale-up

Optimal condition of starch concentration and processing temperature from micro-scale study was used in hydrolysis scale-up. The experiment of starch degradation was assayed in a bioreactor with 2 L of total volume, with mechanic agitator for mixing, and a jacket for heating at operation temperatures. Bioreactors were operated in boat-load, contained 1 L of manioc starch solution, and 20 mL of Forilase NTL® enzymatic solutiont, at constant agitation of 70 rpm and pH 4.8, as it is shown in Figure 1 (Ferreira et al., 2005; Konzula and Liakopoulon-Kyriakides, 2004; Marshal et al., 1999). The glucose concentration ($C_{Glucose}$, g/L) released into bioreactor was measured by DNS method (Miller, 1959). Theoretical glucose concentration ($C_{Starch\ glucose}$, g/L) contained in manioc starch is given in Equation 1 and the hydrolysis yield (Y, %) is given in Equation 2, as follows:

$$C_{Starch\ \ glu\cos e} = \left(\frac{180}{162}\right) * C_{Starch} \qquad (1) \text{ and } Y = \left(\frac{C_{Glu\cos e}}{C_{Starch\ \ glu\cos e}}\right) * 100 \qquad (2)$$

Where 162 and 180 are molecular masses of dextrin monomers and glucose, respectively, and C_{Starch} is the starch concentration into bioreactor (Ferreira et al., 2005; Sleiman and Venturi Filho, 2004).

Figure 1. Bioreactor photo used in hydrolysis assays of manioc starch by amylases from maize malt.

2.2 Modeling of process

New models for starch hydrolyses can be proposed, with base in Michaelis-Menten model for first order kinetics. It uses some considerations to M-M model, showing into Equations 3 and 4, and they were fitted by non linear methods using Origin 6.0 ® software.

Following model had been adjusted to simulate the dependence of [S], the starch, to hydrolysis time (t):

$$[S] = [S]_{eq} + ([S]_0 - [S]_{eq}) * e^{-kt} \qquad (3)$$

While: $[S]_{eq}$ and $[S]_0$ are equilibrium and initial substratum concentrations, and *k* is the kinetic constant of product formation.

To simulate the dependence of conversion rate of starch to reduced sugar (-d[S]/dt = V) the following model was used:

$$V = e^{\frac{V_{max}}{K_M}[S]} \qquad (4) \qquad \text{and} \qquad V_{max} = k * [E]_0 \qquad (5)$$

Being V_{max} and K_M and $[E]_0$ are maxim velocity, Michaelis-Menten constant and initial enzyme concentration, respectively.

2.3 Alcohol production

Starch manioc syrup of optimal hydrolysis assay was used in must manufacture; where it was added and mixed 1 g of $(NH_4)H_2PO_4$, 0.1 g of $MgSO_4$ and sugar mass until obtaining of 50 g/L of total reduce sugar content. The pH was adjusted at 4.5. Fractions of approximately 10 mL, 100 mL and 1 L from the principal vat were distributed among different flasks, referred to as vessels. These were heated in an autoclave and cooled rapidly in running water with the sole objective of sterilization of the medium. *Saccharomyces cerevisae* yeast (Flashmman, Jundiaí -SP, Brazil) at 1 g/L was added into the first vessel (10 mL) and the fermentation process occurred for one day. The total volume of fermented was transferred to the second vessel (500 mL) and the fermentation process occurred for one day. After the end of fermentation in the second vessel, the fermented was transferred to the principal vessel (1 L) until full fermentation of must. All fermentation occurred at 27°C and samples were collected daily for alcohol, total and reducer sugar determinations (Cadogan and Hanks, 1995; Ferreira et al., 2005).

3 Results and Discussions

3 Hydrolysis study

From Table 1 note a hydrolysis yields were above to 45% and in the best condition (55°C and 10 g of starch/L) a yield of about 70% had been finding. According to Lima *et al.* (2001) a full starch hydrolysis is not possible by use of α and/or β-amylases, due these enzymes cannot braking of 1,6 binding of amilopectins. The yields obtained in this work were higher than others research works. For example, Ferreira *et al*. (2005 and 2006) cited yields of about 30% of starch hydrolysis in your work using maize malt amylases at 65°C. Neves *et al*. (2006) observed that increasing the temperature there was a reducing on the hydrolysis yield for trigo starch using microbial amylases. They found yields of about 27.3% at 55 °C and of 14.8% at 75 °C. Leonel and Cereda (2000) obtained a hydrolysis yield of manioc starch similar to Ferreira et al (2005 and 2006).

Table 1 Results of starch hydrolysis yields by amylases at pH 4.8.

Assays	C_{Starch} (g/L)	T (°C)	Y (%)
1	10	35	46.341
2	20	35	45.623

3	10	55	69.636
4	20	55	59.452

Table 2 and 3 show the parameters to the fitting models for knowing the dependence of substratum concentration on influence of reaction time and the dependence of conversion rate on influence of substratum concentration, respectively. As the correlations (R) are about 1.0, there are a good fitting of model to the experimental data, it the model may be used to predict the variation of substratum and glucose concentration into bioreactor in a scale-up of starch hydrolysis process.

Table 2 Parameters of fitting models for describe the dependence of substratum concentration with the hydrolysis time, for starch hydrolysis process by *A. niger* amylases at pH 4.8.

Assays	$[S]_{eq}$ (g/L)	$[S]_0$-$[S]_{eq}$ (g/L)	k (min^{-1})	R
1	5.3005	4.0040	46.950	0.9663
2	10.066	9.3453	53.998	0.9756
3	2.5592	5.7952	40.658	0.9322
4	8.3988	10.647	19.437	0.9726

Values of V_{max} were obtained from $[E]_0$ (0.2243 g/L) and k values substituted into Equation 5 and 4, as showing in Table 3. It observed an increase in *k* and V_{max} values to the starch concentration at 35°C and at 55°C, this behavior was inversed, due to the enzyme inactivation for long exposition time at high temperature. Minor K_M introduces a high affinity of enzyme to the substratum, it was found at 55°C (Forgaty and Kelly, 1979; Lima et al., 2001; Reguly, 2000; Wiseman, 1987).

Table 3 Parameters of fitting models for describe the dependence of conversion rate with the substratum concentration, for starch hydrolysis process by *A. niger* amylases at pH 4.8.

Assays	A	V_{max}/K_M	V_{max}	K_M	R
1	5.10^{-5}	1.0580	10.530	9.9528	0.8649
2	1.10^{-3}	0.3350	12.110	36.152	0.9964
3	3.10^{-4}	0.8461	9.1187	10.777	0.9556
4	$6.1.10^{-3}$	3.2610	4.3594	1.3368	0.9624

Figures 2 and 3 show the experimental and simulated starch hydrolysis processes at 35 and 55°C, respectively. It notes that the predicted and experimental data had similar behavior, it shows a good adjust of proposed models.

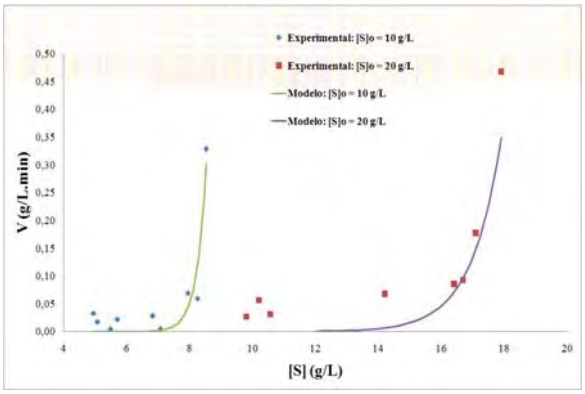
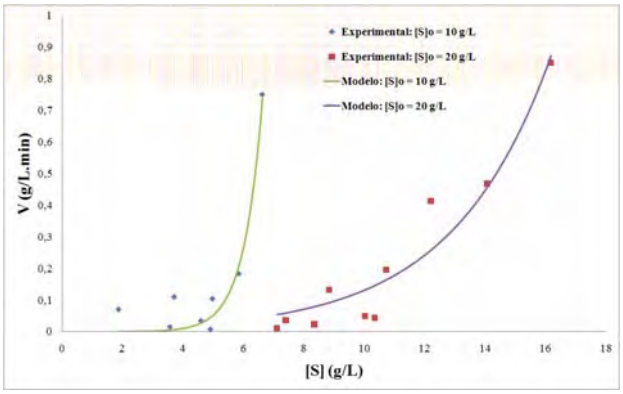
b

Figure 2. Experimental and simulated data, of behavior of substratum concentration ([S]) on influence of reaction time (t) at pH 4.8. a) at 35°C and b) at 55°C.



A



B

Figure 3. Experimental and simulated data to observe the behavior of conversion rate (V) on influence of starch concentration ([S]) at pH 4.8. a) at 35°C and b) at 55°C.

3.2 Fermentation

Figure 4 show the alcohol and reduce sugar varying to fermentation time, for the syrup must fermentation by S. cerevisae. After end fermentation process, an alcohol content of 3.4°GL and alcohol yield of 45% had found. This yield is high, for the maxim alcohol yield is of 51.11%, according to Ferreira et al. (2005 and 2006), Lima et al. (2001) and Reguly (2000). There was starch hydrolysis by amylase during the fermentation process, for the sugars produced of starch hydrolyses (amylase inhibitors) were consumed during fermentation time (Forgaty and Kelly, 1979; Lima et al., 20001; Reguly, 2000)

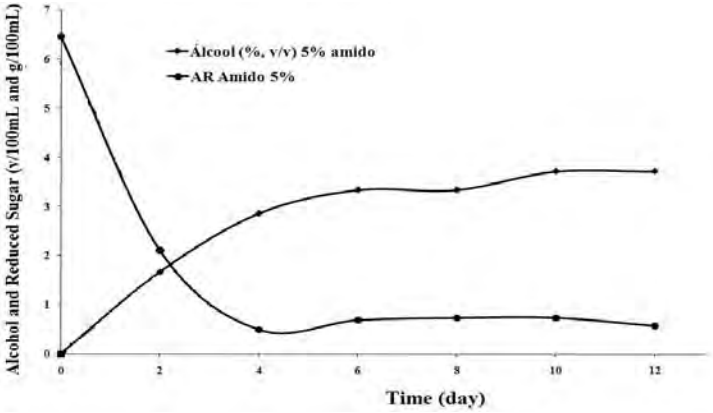


Figure 4. Curves of fermentation of manioc must.

Alcohol yield was more than 39% obtained by Ferreira *et al* (2005 and 2006) and more than 27% obtained by Neves et al. (2006).

4 Conclusions

Results showed that exponential models fitted more than other models. These models possible to simulate the hydrolysis process by amylases and its scale-up of this process. On starch hydrolysis, it perceived that in optimal condition the hydrolysis yield got 80%. After fermentation an alcohol yield above of 45% was gotten (the theoretical is 51.1%). This work showed as to obtain alcohol of manioc root starch, as alternative to the substitution of the sugar-cane juice in alcohol production.

Keywords: maize malt, purification, amylases, alcohol, acetone.
Topic: Integration of life sciences & engineering Suitable.

Abstract: This work aimed to purify the amylases from maize (*Zea mays*) malt by solvent precipitation and it biochemistry characterization. A 2^3 factorial planning was making to study the effects of pH, temperature and concentration and type solvent (alcohol or acetone) on the enzymes purification index. Malt was obtained by maize seed germination for five days on controlled home conditions. Larges recovery index were found for alcohol precipitation. Square model was the best fitting to description of amylase purification from maize malt by alcohol precipitation process. RSM showed that optimal condition to amylase precipitation was obtained at 10°C, on a pH 7 and 0.7 (w/w) of alcohol concentration, while a purification factor of 10 times was obtained. Optimal pH was obtained between 4.5 and 6.5 and optimal temperatures were of 50°C for β-amylase and 90°C for α-amylase and the values of K_M and V_{max} constants was of $7.69.10^{-2}$ g/L and $7.69.10^{2}$ g/L.min, respectively.

1 Introduction

The enzymes α-amylase (EC 3.2.1.1, α-1,4 glucan 4-glucanhydroxylase) and β-amylase (EC 3.2.2.1 α-1,4 glucan 4-malthydrolase) with a molecular weight of about 50 kDa, are exoenzymes that simultaneously degrade starch to produce glucose, maltose and boundary dextrins, which are much utilized in food industries (Aguilar et al., 2000; Biazus et al., 2005). Their optimum pH is 4.8 and 5.4 and optimum temperature is 75 °C and 55 °C, respectively. According to Sigma (1996), the price of amylases enzymes is about U$ 1,500/gram of purified material.

The partition coefficients of hydrolytic enzymes, α- and β-amylases and glucoamylase, of high purity, have been determined in PEG/dextran (Furuya et al., 1995 and 1996), PEG/$MgSO_4$ (Blásquez et al., 1998) and PEG/$CaCl_2$ (Curvelo-Santana, 2003) batch aqueous two-phase systems (ATPS). The influence of polymer, salt and initial enzyme concentration on partition was investigated in these studies. The experimental and correlated amylase concentration by method Flory-Huggins equation into PEG/dextran and PEG/$MgSO_4$ were measured between 0.04 and 0.97. Curvelo-Santana (2003) had concentred in 5-fold the α- and β-amylases from maize malt into PEG/$CaCl_2$ ATPS, and Gu and Glantz (2007) had concentrated in 3-folds for corn protein into PEG/NaCl ATPS. Nirmala and Muralikrishna (2003) had purified the amylase from malt of *Finge millet* by gel chromatography and 3-folds of recovery index had been found.

This work aimed to purify the amylases from maize (*Zea mays*) malt by solvent precipitation and it biochemistry characterization. A 2^3 factorial planning was making to study the effect of pH, temperature and solvent (alcohol or acetone) concentration on the enzymes recovery index.

2 Material and Methods

2.1 Making of the maize malt

The maize seeds were selected, their weight was measured, and the seeds washed. The seeds were soaked in water until water absorption was 40–45% (w/w), and germinated in laboratory. The germination time was between 4–5 days. The maize malt was dried at 55°C and tritured. A 2% maize malt solution in phosphate buffer had been made (Biazus et al., 2005; Curvelo-Santana, 2003).

2.2 Enzyme assays

Amylase activities were measured according to DNS method (Miller, 1959). 20 mL of 2 % soluble starch at pH 4.8 (0.1 M acetate buffer) were hydrolyzed by 500µL of enzyme sample in 10 min at 30±2 °C (Biazus et al., 2005; Reguly, 1996). Total protein concentration was determined according to the dye binding method of Bradford (1976) with BSA as protein standard. One unit of enzyme activity was defined as µmol of glucose released per min under the assay conditions. The specific activity was calculated as activity for mg protein.

2.3 Fractional precipitation

Enzyme precipitations were released with alcohol or acetone solvents on controlled pH and temperature; at home pressure. For pH and temperature controls the 0.1M phosphate buffer and thermal batch had been used. Into assay tubes, volumes of maize malt solution and solvent were placed until a 10 mL of total volume had been got. Volumes of maize malt and solvents had been varied in the volumetric proportion (v/v) of according factorial design of Table 1. Activity and total protein were measured in crude and purified samples (Luccarini et al., 2005; Teotia et al., 2003).

2.4 Recovery index (IR)

Pirification eficience was measured using the recovery index (IR) calculated from theEquation 1.

$$\mathrm{IR} = \frac{\mathrm{SA}_{\mathrm{phase}}}{SA_{crude}} \qquad (1)$$

where $SA_{purified}$ is the specific activity (U/mg of protein) in the evaluated purified sample and SA_{crude} is the specific activity in *Zea mays* malt (U/mg of protein).

2.5 Experimental design

Orthogonal experimental designs by modified star methods was used in the optimization of amylase purification from maize malt by frational precipitation with alcohol or acetone solvents. Three factors were used: solvent concentration (x_1), precipiting temperature (x_2) and precipiting pH (x_3), and one response, the recovery index (IR). The assays are shown in Table 1; the level changed as follows: –1, 0, +1, and α = ± 1.414, with three repetitions in the center point (Barros Neto et al., 2001; Biazus et al., 2005).

$$x_1 = \frac{C_S - 0.5}{0.2} \qquad (2); \qquad x_2 = \frac{T - 20}{10} \qquad (3) \text{ and } x_3 = pH - 6 \qquad (4).$$

Where C_S and T are solvent concetration and precipiting temperatore.

The evaluation of the empiric models was performed by variance analysis (ANOVA) and optimization by response surface methodology (RSM) in the program Statistics for Windows 7.0 (Barros Neto et al., 2001). The planning design used to obtain the optimal condition for recovery of amylases from maize malt by fractional precipitation is shown in Table 1.

2.6 Enzyme characterization

The optimum pH of the enzyme was determined by measuring its activity, after 10 min of reaction, in the pH range varying among 3.0–10.0 at 30±2 °C. The optimum temperature was obtained by measuring its activity after 10 min, among 10 at 95±2°C,

using some soluble starch solution in 0.1 M acetate buffer at pH 4.8. Initial rates of starch hydrolysis were determined at various substrate concentrations (0.01–20 mg/mL). The kinetic constants K_m and V_{max} were estimated by Lineweaver–Burk method (Aguilar et al., 2000; Biazus et al., 2005; Nirmala and Muralikrishna, 2003; Reguly, 1996).

3 Results and Discussion

Table 1 shows experimental design used in this work, so as, its results for alcohol and acetone precipitation. It notes that the purification factors of alcohol precipitation were more than acetone precipitation, and only three assay of amylase purification by acetone precipitation had been effective. Thus, the RSM optimization will be make for alcohol precipitation, only.

Table 1 Experimental design and results to optimize the maize malt amylase precipitation.

Assays	C_S (v/v)	*T* (ºC)	*pH*	x_1	x_2	x_3	$IR_{Alcohol}$	$IR_{Acetone}$
1	0.3	10	5	-1	-1	-1	0.2867	0
2	0.7	10	5	1	-1	-1	3.0243	0
3	0.3	30	5	-1	1	-1	0	0
4	0.7	30	5	1	1	-1	0	4.0733
5	0.3	10	7	-1	-1	1	3.9617	5.9685
6	0.7	10	7	1	-1	1	9.6337	0.7446
7	0.3	30	7	-1	1	1	2.7312	0
8	0.7	30	7	1	1	1	0	0
9	0.5	20	6	0	0	0	1.0349	0
10	0.5	20	6	0	0	0	0	0
11	0.5	20	6	0	0	0	0	0
12	0.2	20	6	-1.682	0	0	0	0
13	0.8	20	6	1.682	0	0	3.0458	0

Where: C_S is solvent concentration, T and pH are precipitating temperature and pH, respectively, and $IR_{Alcohol}$ and $IR_{Acetone}$ are recovery index for alcohol and acetone solvents.

ANOVA results showed multiple correlation (R^2) was about 1.0. Calculated F were higher than 2 times and minor than 3 times of the tabled F; these introduce that model had been fitted to the experimental data (Barros Neto et al., 2001).

Table 2 Anova to evaluation of the model for optimization of alcohol precipitation of amylase from maize malt

R^2	0.9313
Test F_1*	2.1932
Test F_2*	0.2825

*F test = calculated F/Tabled F

Square model was the best fitting among the models tested. Fitted model for alohol precipitation are shown at follown.

$$IR = 0.8161 + 0.7908.C_{Alcohol} - 1.7719.T + 1.6269.pH + 1.6386.T^2 - 1.3926.C_{Alcohol}.T - 0.0254.C_{Alcohol}.pH - 0.9441.T.pH \quad (5)$$

Figures 1.a, 1.b and 1.c are the response surfaces to obtain the best conditions of

amylase purification from maize malt by alcohol precipitation. By RSM optimization, the best condition to amylase purification from maize malt by alcohol precipitation are: 10°C on a pH of 7 and an alcohol concentration of 0.7 (v/v). In this condition a recovery index of about 10 times is obteined. This index is more than found by Furuya et al (1995 and 1996), by Blázquez et al. (1998) Gu and Glantz (2007), Nirmala and Muralikrishna (2003) and Curvelo-Santana (2003).

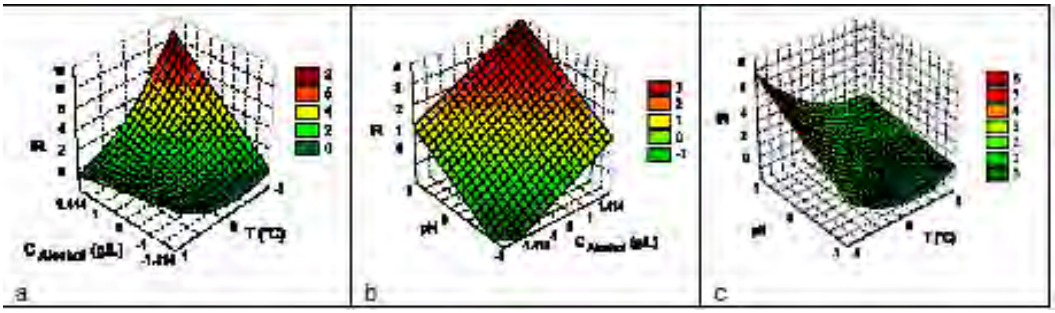

Figure 1. Response surfaces to know effects of factores on recovery index (IR) of amylase from maize malt. a) Effects of alcohol concentration and temperature; b) Effects of pH and alcohol concentration and c) Effects of pH and temperature.

Figure 2.a shows that the maize malt amylases kept 80% of the activity in a pH range between 4.5 and 6.5. Figure 2.b shows that there are two optimum temperatures: one at 50 °C, due to β-amylase activity and the other at 90 °C, due to that of α-amylase. Figure 2.c shows the derivation of the K_m, and V_{max} constants using Lineweaver–Burk method; their values were 7.69×10^{-2} g/L and 7.69×10^{2} g/L.min (or 2.48×10^{4} U/mg), respectively.

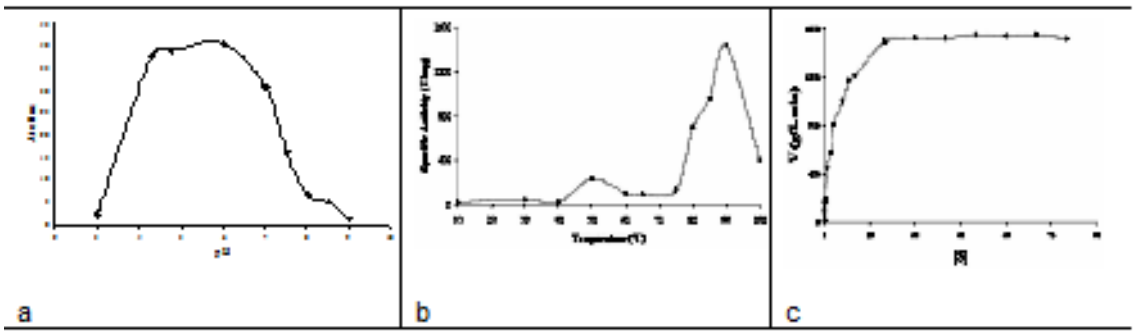

Figure 2. Enzyme characterization of amylase from maize malt. a) Effect of pH; b) Effect of temperature and c) Starch hydrolysis kinetic.

4 Conclusion

Alcohol is the best solvent to the amylase precipitation from maize malt than acetone. A square model was the best fitting to description of amylase purification from maize malt by alcohol precipitation process. RSM shows that optimal condition to amylase precipitation was obtained at 10°C, on a pH 7 and 0.7 (v/v) of alcohol concentration, while a purification factor of 10 times was obtained. Enzyme characterization showed an optimal pH was obtained between 4.5 and 6.5 and optimal temperatures were of 50°C for β-amylase and 90°C for α-amylase and the values of K_M and V_{max} constants was of $7.69.10^{-2}$ g/L and $7.69.10^{2}$ g/L.min, respectively.

Topic: Integration of life & engineering

Abstract

Corn cob samples were treated with water (autohydrolysis reaction) using a liquid to solid ratio of 10:1 w/w. The optimal condition for extraction of hemicelluloses was found at 185ºC for 30 min. This resulted in the release of 9.7% of hemicelluloses (% dry starting material), corresponding to the dissolution of 27.9% of the original hemicellulose. Chemical composition and physico-chemical properties of the samples were elucidated by a combination of sugar analyses and thermal analysis. The results showed that the treatment was effective on the extraction of hemicelluloses from corn cob and that the TGA analysis of xylan from birch wood was found to be initially degraded at about 220 ºC whereas hemicelluloses from corn cob would be degraded at about 225 ºC.

1 Introduction

Agricultural wastes are mainly of lignocellulosic nature (with cellulose, hemicelluloses and lignin as structural components). Chemically, about 35-55% of the dry material is the glucose polymer cellulose, much of which is in a crystalline structure; while another 25-35% is hemicellulose, an amorphous polymer. The remainder is mostly lignin plus less amounts of minerals, waxes, and other compounds (Sun and Cheng, 2002). Cellulose is formed by β(1-4) glucosyl linkages in a linear backbone, whereas hemicelluloses are branched polymers composed of several monosaccharides (Fengel and Wegener, 1989).

Treatments of lignocellulosic materials in autohydrolysis processes (or hydrothermal treatments), under optimized conditions, lead to the solubilisation of hemicelluloses, leaving a solid phase enriched in both cellulose and lignin. These aqueous processes, when used in mild conditions, are an environmentally friendly technology for biomass utilization (Garrote et al., 1999).

On the other hand, corn is the one of the most widely planted crops in the World. According to the Food and Agriculture Organization of the United Nations (FAO, 2008), the annual production worldwide is about 695×10^9 kg. The major production regions are the American continent (53%), Asia (29%), and Europe (11%). In particular, corn cob is an important by-product of this industry: for every 100 kg of corn grain approximately 18 kg of corn cobs are produced (Torre et al., 2008). A large quantity of corn cobs remains unused as lignocellulosic waste or used as animal feed. Owing to their chemical composition, corn cobs show great potential as a renewable raw material for producing a variety of added-value chemicals (Rivas et al., 2004).

* Corresponding author. Tel + 351-253-604400. E-mail: ruzeneds@hotmail.com

The hemicelluloses fraction of corncobs has a comparatively high content of acetylated xylan (a polymer made up of xylose units with acetyl substituents). When corn cobs are contacted with water and heated, the hydronium ions coming from water autoionisation cause both xylan depolymerisation (sugar oligomers and sugars) and cleavage of acetyl groups (to give acetic acid, which increases the hydronium concentration in the reaction medium) (Garrote, 2002). Autohydrolysis solid residues which contain mainly cellulose and lignin can be subjected to further chemical or biotechnological processing and can also be used as substrate for conversion into a variety of marketable end-products (Parajó et al., 1994).

The aim of this work is to assess the effect of the autohydrolysis treatment of corn cob on the hemicelluloses yield with particular emphasis on the further applications of the extracted fractions.

2 Materials and Methods

Materials

Corn residues (corn cob) were kindly supplied by a local farmer (Portugal). After being dried at 40 ºC in an oven for 12 h, the corn cob was cut into small pieces (1-3 cm), milled in a knives' mill to pass through a 0.4 mm screen (for chemical composition) and 1.0 mm (for hydrothermal pre-treatments), and stored at room temperature. All chemicals used were of analytical or reagent grade. Experiments were performed in triplicate and yields are given on a dry weight (untreated corn cob) basis.

Chemical composition of corn cob

Two grams of ground corn cob were treated with 10 mL of 72% H_2SO_4 under stirring at 45 °C for 7 min. The flask was autoclaved for 30 min at 1.05 bar for the complete hydrolysis of oligomers. After filtration through a Sep-Pak C18 cartridge to remove aromatic compounds, the hydrolysate was analyzed in a MetaCarb 67H column at 45 °C using a Shimadzu chromatograph with refractive-index detector. The mobile phase was 0.005 mol/L H_2SO_4 at 0.6 mL/min flow rate. Sugar concentrations, reported as glucan and xylan, were determined from calibration curves obtained with pure compounds. Lignin was determined by gravimetric analysis (Rocha, 2000). All experiments were performed in triplicate.

Hydrothermal treatments

Corn cob samples and water were mixed in a closed and pressurized vessel in order to obtain a liquid/solid ratio of 10:1 w/w, taking into account the moisture content of the sample. The reactor was heated to the desired temperature (165-195 ºC) by periods ranging from 10 to 60 min. After each treatment, the liquid phase was separated from the solids by filtration. The hemicelluloses were then precipitated by pouring the concentrated supernatant fluid with three volumes of 95% ethanol (20 °C, 24 h). The precipitates were recovered by filtration, washed with 70 % ethanol and dried (30 ºC). All experiments were performed in triplicate.

Thermogravimetric Analyzer

The thermal stability of the samples was evaluated using thermogravimetric analysis (TGA) on a thermal analyzer (TGA-50 Shimadzu, Japan). The apparatus was continually flushed with nitrogen. The samples weighed between 10 and 12 mg and were run from room temperature to 580 °C at a rate of 10 °C/min.

3 Results and Discussion

The compositional data of the corn cob samples used as raw material (average of three replicates) are shown in Table 1. The results are expressed as glucan, hemicelluloses and lignin. Thus, lignocellulosic materials can be defined by their contents of glucan (corresponding to cellulose), xylan (measured as xylose equivalent, which forms the main polymer backbone), xylan substituents (arabinose units, reported as arabinan expressed in sugar equivalent, and acetyl groups), and total lignin (measured as soluble lignin and Klason lignin). As can be seen from Table 1, xylan and xylan substituents (hemicelluloses) accounted jointly for 34.7% of corn cobs (in oven-dryed basis).

Samples of corn cob were subjected to hydrothermal treatments in aqueous media under conditions leading to maximal hemicellulose yield. Figure 1 shows that the treatment of corn cob released 0.28 - 9.68 % hemicelluloses (in respect to dry starting material), corresponding to the dissolution of 0.8 and 27.9 % of the original hemicelluloses, respectively. These results revealed that autohydrolysis of the corn cob was effective, and that the highest extraction yield was obtained with 30 min and 185 ºC (27.9% of the total available hemicelluloses).

Table 1. Chemical composition of corn cob

Chemical Components	Composition (%)
Glucan	31.8 ± 0.8
Hemicelluloses	34.7 ± 1.1
Xylan	29.4 ± 0.2
Arabinan	1.1 ± 0.2
Acetyl group	3.1 ± 0.4
Total lignin	27.9 ± 0.4
Soluble lignin	11.3 ± 0.2
Klason lignin	16.6 ± 0.4
Total Composition	93.3 ± 0.9

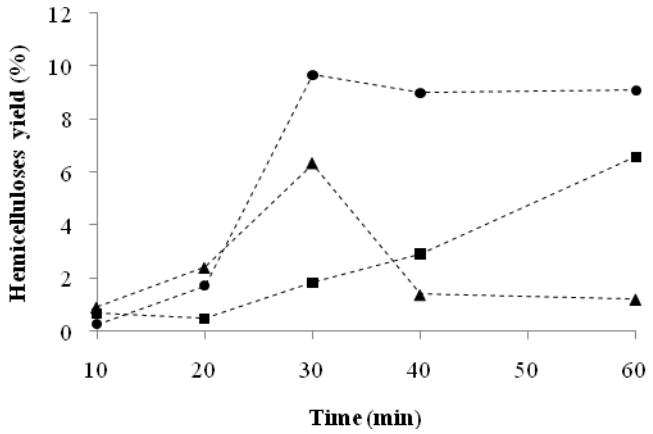

Figure 1. Hemicelluloses yield (%) at temperatures of (■) 165 ºC, (●) 185 ºC and (▲) 195 ºC.

In this work, the thermal properties (Figure 2) of xylan from birch wood (line 1), hemicelluloses from corn cob at 165ºC/60 min (line 2), 185ºC/30 min (line 3) and 195ºC/30 min (line 4) were studied by TGA. Figure 2 and Table 2 show the TGA results obtained of xylan from birch wood and hemicellulose from corn cob. There is distinction between the amounts of the residues remaining after heating of 560 ºC heating. All samples have a residual weight between 4.4 and 16.5% at 560 ºC (Table 2).

Table 2. Degradation characteristics of the xylan from birch wood, hemicellulose from corn cob at 165ºC/60 min, 175ºC/40 min, 185ºC/30 min and 195ºC/30 min.

Samples	Onset of degradation (ºC)	Residue after 560 ºC (%)
Xylan from birch wood	270	16.5
165 ºC/60 min	250	10.9
185 ºC/30 min	240	4.4
195 ºC/30 min	240	11.9

Samples of xylan from birch wood were found to be initially degraded at about 220 ºC whereas hemicelluloses from corn cob at 165ºC/60 min, 185ºC/30 min and 195ºC/30 min would be degraded at about 225 ºC. Maximum rates of weight loss were observed between 230 and 320 °C. As observed, samples were stable up to 200 °C. Beyond these temperatures, thermal degradation takes place. As can be seen (Figure 2), for a 30% weight loss, the decomposition temperatures of the degraded samples occurred at 220 °C (lines 2-4) and 280 °C (lines 1). No thermal events were observed at temperatures higher than 560ºC.

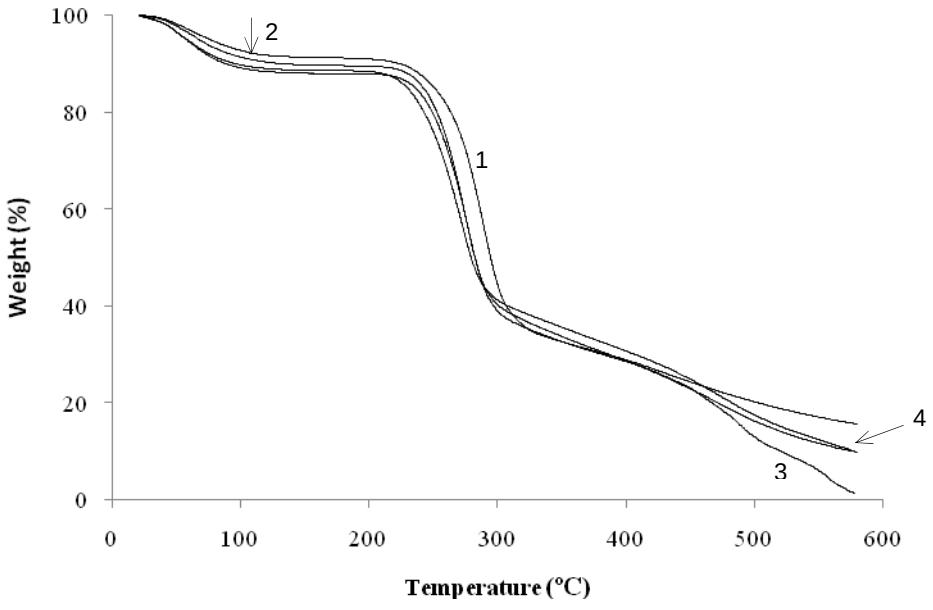

Figure 2. TGA curves of commercial xylan from birch wood (line 1), hemicelluloses from corn cob at 165ºC/60 min (line 2), 185ºC/30 min (line 3) and 195ºC/30 min (line 4).

4 Conclusion

The autohydrolysis treatment of corn cob was effective for the hemicelluloses extraction, and it was shown that the best conditions of extraction were at 185ºC and 30 min, obtaining 27.9% of the total available hemicelluloses. Degradation characteristics of hemicellulose (185ºC/30min): onset of degradation at 240 ºC and residue after 560 ºC of 4.4 %.

Topic: Integration of life sciences & engineering.

Abstract

The primary aim of the presented study was design of an enzymatic reaction cascade on which an industrially applicable process can be based on, implying the enzymes xylose isomerase, xylulose kinase and phosphoketolase, which convert xylose derived from lignocellulolsic wastes into a high-value-added product, glyceraldehyde-3-phosphate. The xylose conversion to gliceraldehyde 3-phosphate was carried out by a dynamic reactor-cascade system, made up of three modules each of them containing a substrate conditioning element, a fixed-bed reactor and an adequate storage tank. The modular form permitted analysis of each of the enzymatic processes, assuring at the same time, separation of the obtained products.

Introduction

For the sustainable use of lignocellulose-containing wastes produced by paper industry, both chemical and biotechnological procedures are used; chemical procedures represent in many cases a high environmental hazard and less valuable products. The biotechnological procedures are more effective and have reduced environmental impact; these procedures being conducted based on bioconversions performed by enzymes of different microorganisms, as well as by whole-cell systems, which function as biocatalysts. By the aid of these processes the lignocellulosic biomass and its derivatives can be converted to ethanol or other organic raw materials for the chemical industry. However, these procedures have been applied as bases of industrial technologies only at a low level. Processing of industrial and agricultural byproducts with high lignocellulosic contents can be achieved in the first phase by hidrolysis carried out eighter by chemical or by enyzmatic reactions, the free sugars resulted by these processes can be further utilized for obtaining different products.

Xylose conversion had been studied extensively in order to achieve obtention of high-value added products by processes which can easily been scaled-up. Fermentative processes have been studied more in detail in both the case of yeasts and bacteria (Kuyper et al., 2005; Taniguchi et al., 2004), genetically modified strains, as well as metabolic engineering approaches had been used (Nyyssola et al., 2005). In fermentation approaches, xylose utilization as a sole carbon source has been a limiting factor, as even recombinant micrroganisms require additional sugar source for their growth (Krishnan et al., 1999). Xylose metabolism in bacteria has been described for a wide array of microorganisms including *Escherichia coli* (Lawlis et al., 1984)

[*] Corresponding author. Tel + 40745.100.924. E-mail:lanyiszabolcs@sapientia.siculorum.ro

Lactobacillus ssp (Bor et al., 1992), *Staphylococcus xylosus* (Sizemore et al., 1991) and *Lactococcus lactis* (Erlandson et al., 2000). Xylose metabolism involves gene products of the *xylA, xylB* genes in the first phase, which yields xylulose-5 phosphate, a common intermediate for reactions of the pentose metabolism. During heterofermentative degradation in lactic acid bacteria, xylulose-5 phosphate is further converted via the phosphoketolase pathway. We designed an enzymatic reaction cascade on which an industrially applicable process can be based on, implying the enzymes xylose isomerase, xylulose kinase and phosphoketolase, which convert xylose derived from lignocellulolsic wastes into a high-value-added product, glyceraldehyde-3-phosphate. The figure below illustrates the enzymatic process yielding a high added-value product starting from xylose derived from lignocellulose, which is converted to glyceraldehyde-3-phosphate in three metabolic steps. The partial enzymatic reactions can be found in several microbial organisms, different organisms having slightly different enzymes for the three reactions and require specific conditions for optimal activity.

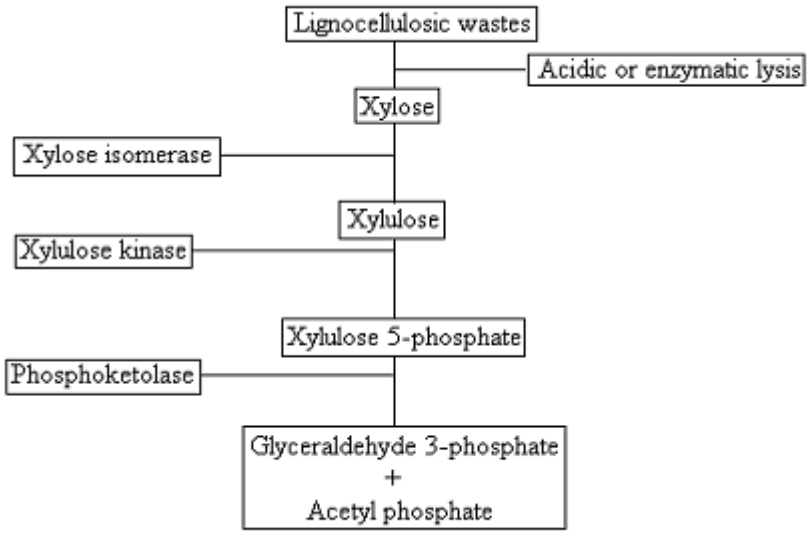

Figure 1. Conversion of xylose into glyceraldehyde-3-phosphate.

Realization of a bioprocess with such a complexity, even at a laboratory or small-scale level requires a reliable chemical, biochemical and technological background. Even if the biochemical and enzymatic part is solved, the technological scale-up raises many problems, particularly if continuous systems are to be used.

The first reaction is known to work well in industrial applications at high concentrations, but the second and third reactions, working with millimolar concentrations have not been optimized yet at larger scale. The overall yield of the process is limited by the second reaction, which results in xylulose-5-phosphate, as coupling to the first isomerization reaction presents difficulties due to the different scales. Standard biochemical experiments work with material quantities of µg or mg order of magnitude, whereas scaling-up of enzymatic bioconversions usually requires materials in a quantity with at least one order of magnitude higher; methods for recombinant enzymes obtained at laboratory scale thus present a disadvantage when used in prefabricated bioreactors. By this we considered design of a unique reactor system to conduct the studied process.

Materials and methods

Enzymes

To perform the first isomerization reaction, immobilised xylose isomerase commercialized as Sweetzyme was used (Novo Nordisk). Recombinant plasmids containing the coding regions for xylulose kinase (pET28a(+)-*XylB*) and xylulose 5-phosphate phosphoketolase (pHAT2-*PK*) used for heterologous expression of the enzymes were obtained as a courtesy of Stefan Szedlacsek, Department of Enzymology, Institute of Biochemistry (Bucharest).

Obtention of the enzymes xylulose-kinase and phosphoketolase was carried out by modified protocols after by Sambrook, J. (1989). For the enzyme D-xylulose-5-phosphokinase, as expression host the *E.coli* strain BL21 (DE3) pLysS was used, whereas in the case of phosphoketolase derived from *Leuconostoc mesenteroides*, the recombinant protein was obtained in *E. coli* strain BL21(DE3)RIL.

Immobilization of both xylulose kinase and phosphoketolase was carried out taking the advantage of the N-terminal 6XHis tags present as fusion partners of the expressed enzyme preparates. One step purification and immobilization of the obtained proteins was achieved by binding to the chelating matrix Porfinity IMAC Ni^{2+} Charged Resin (BioRad), which was found to be the optimal matrix from the point of view of binding capacity and reduced cation leakage.

In the first reaction, xylose was converted to xylulose in an equilibrium reaction by the immobilized xylose isomerase derived from *Streptomyces murinus*, having its temperature optimum at 60 °C, by which a conversion rate of 25% was obtained. As the reaction product raised the problem of the presence of xylose, which inhibits phosphoketolase activity required in the last phase of the transformation; the resulted mixture was separated in xylose and xylulose. Xylulose was phosphorilated by the heterologuosly expressed enzyme D-xylulose-5-phosphokinase in the presence of ATP in a subsequent reaction, in which a conversion rate of 90% was achieved. The expressed xylulose 5-phosphate phosphoketolase was used to carry out the final step of the xylose conversion reaction. The final reaction performed by the obtained phosphoketolase was conducted at 37 °C, in the presence of inorganic phosphate as well as of the cofactor Mg2+ and

Product separation and determination of catalytic efficiency

Activity assays of the xylose isomerase and xylulose kinase, respectively were realized with a Varian Pro Star HPLC, detector RI Varian Pro Star 350, on a Supercosil LC NH2 column, using 0,01 N sulfuric acid as elution agent at a 0,5 ml/min flow rate. The first reaction was performed starting from 1 M xylose and the resulted product was separated on boric acid (2 ml, Sigma). For separation, the product mixture was diluted to contain 0,01 mM xylulose. The second reaction was fed with the separated xylulose and 4 mM ATP.

Characterization of catalyitic properties of the obtained phosphoketolase was carried out by determination of conversion of xylulose 5-phosphate to glyceraldehide 3-phosphate under optimized conditions, showing a specific activity of 0.5-0.6 U/mg.

The conversion in glyceraldehyde 3-phosphate was followed by indirect determination by coupled reactions with the enzymes triose isomerase (TIM) and glyceraldehyde dehydrogenase (GDH), measuring the decrease in NADH concentration. The auxiliary implicated enzymes were added to the system in excess, so that the reaction rate only depended on phosphoketolase activity.

Reactor

The xylose conversion to glyceraldehyde 3-phosphate was carried out by a dynamic reactor-cascade system, set up of three modules each of them containing a substrate conditioning element, a fixed-bed reactor and an adequate storage tank. The modular form permitted analysis of each of the enzymatic processes, assuring at the same time, separation of the obtained products. With the modular design the separation of the different processes can be solved and by changing the reactor charge, the separation

of products can be achived as well. The modules are equipped with thermostats and product collector tanks.
Materials that make up the reactos were chosen in order to prevent microbial contamination of the reactor system, which inhibit biofilm formation and can easilly be disinfected.

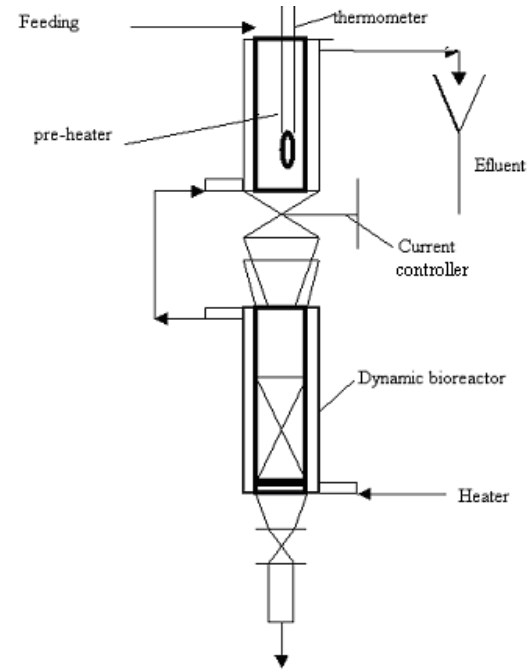

Figure 2. Module of the bioreactor system.

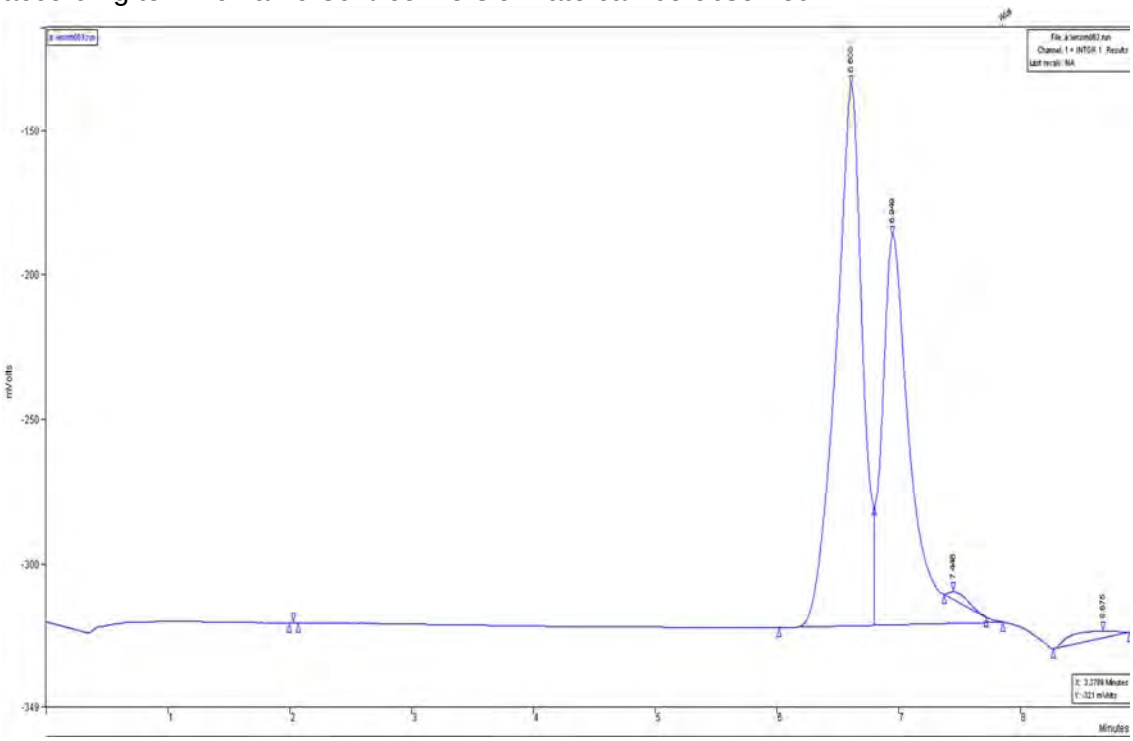
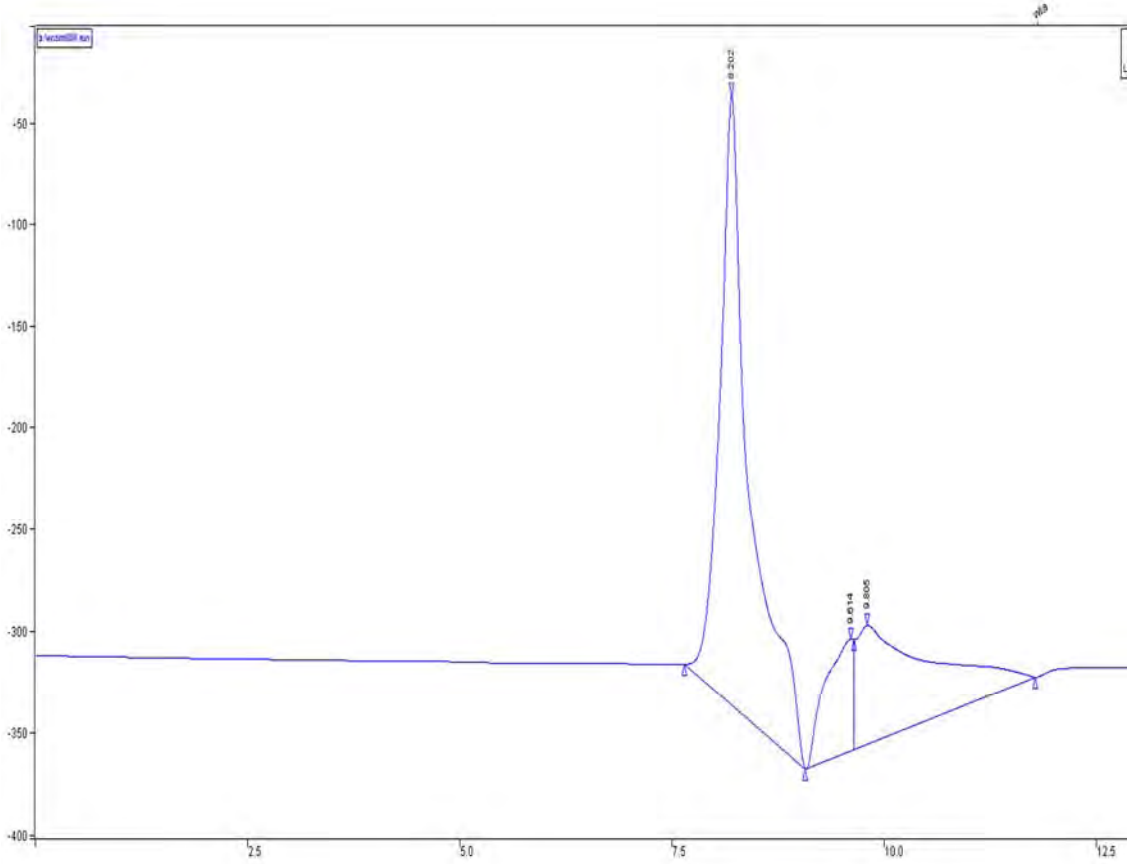
Results and discussion

Xylose conversion to xylulose. The chromatogram below referres to the reaction products of the first enzymatic conversion products, the xylose/xylulose mixture, according to which a 70-30% conversion rate can be observed.



Chromatogram 1. The xylose-xylulose conversion reaction products.

Xylulose-xylulose-5-phosphate conversion. Regarding the xylulose phosphorylation step, the HPLC separation of the resulted reaction products indicates a 90% conversion yield, the 10% difference containing errors of concentration determinations. The chromatogram presented below illustrates separated products of the xylulose-xylulose-5-phosphate conversion, catalyzed by the obtained xylulose kinase.



Chromatogram 2. Reaction products of the xylulose- xylulose-5-phosphate conversion.

Obtention of glyceraldehyde-3-phosphate. In case of the third reaction, the obtained phosphoketolase was assayed for activity in both free and immobilized form, as presented in tables 1. and 2., a 15%-20% activity decrease being observed in the case of the immobilized form.

The reaction performed in the designed reactor system did not achieve the yield presented by the free enzyme; enzyme stability of the expressed phosphoketolase needs to be correctly correlated in order to achieve better conversion yield, optimization studies of the third reaction are in progress.

Free phosphoketolase	Probe 1.	Probe 2.	Probe 3.
ΔA/Δt	0,089	0,086	0,112
Activity U/mg	0,541	0,523	0,681

Table 1. Activity of the free enzyme.

Immobilized phosphoketolase	Probe 1.	Probe 2.	Probe 3.
ΔA/Δt	0,069	0,067	0,057
Activity U/mg	0,419	0,407	0,346

Table 2. Activity of the immobilized enzyme.

Conclusions

Despite the rather low conversion rate achieved by the designed reactor system; it can be a solution for lignocellulosic waste utilization and processing after optimization.
The study has a demonstrative importance regarding viable possibilities of replacing chemical procedures with enzymatic and biotechnological solutions.

Topic: Integration of life sciences and engineering.

Abstract

The individual and combined effects of initial lactose concentration, temperature and inoculum concentration on ethanol production from cheese whey powder by *Kluyveromyces fragilis* were investigated. A 2^3 full-factorial central composite design (CCD) and response surface methodology (RSM) were employed in order to determine the optima conditions that maximize the ethanol production. Statistical analysis of results showed that, in the range studied, only the initial lactose concentration had a significant effect on ethanol production. Response surface data showed maximum ethanol production at inoculum concentration between 1 and 3 g/L and temperature between 25 and 35ºC when the initial lactose concentration was 150 g/L.

1 Introduction

The dairy industry represents an important part of the food processing industry and contributes significant liquid wastes that can be used for the production of ethanol (Ghaly and El-Taweel, 1997). Cheese whey (CW), a by-product of the cheese manufacturing process whose major components are lactose (44-52 g/L), proteins (6-8 g/L) and mineral salts (4-9 g/L), constitutes an inexpensive and nutritionally rich raw material for the production of ethanol by fermentation. However, the production of ethanol from unconcentrated CW is not economically feasible because the levels of ethanol obtained at the end of fermentation reach only about 2%, making the distillation process too expensive. Otherwise, costs are significantly reduced with the increase of lactose concentration up to about 100-120 g/L lactose (González Siso, 1996). Therefore, dry cheese whey powder (CWP) may be an attractive raw material for ethanol production. CWP is a dried and concentrated form of CW and contains lactose in addition to nitrogen, phosphate and other essential nutrients (Kargi and Ozmihci, 2006). The use of CWP instead of CW for ethanol fermentations has significant advantages such as elimination of costly ultrafiltration processes to concentrate lactose before fermentation, compact volume, long-term stability and high concentrations of lactose and other nutrients yielding high ethanol concentrations by fermentation (Ozmihci and Kargi, 2007a).

Optimization of fermentation conditions by the classical method involves changing one independent variable while fixing all others at a fixed level. This is extremely time-consuming and expensive for a large number of variables (Adinarayana et al., 2003) and also may result in wrong conclusions (Oh et al., 1995). Response surface methodology (RSM) is a collection of statistical techniques for designing experiments, building models, evaluating the effects of

factors, and searching optimum conditions of factors for desirable responses (Li et al., 2001). Although this method was successfully applied in many areas of biotechnology, there is no report in the literature describing the influence of process parameters on the production of ethanol from CWP through RSM.

The present study aimed to optimize the conditions for ethanol production from CWP through RSM designed with composite central design (CCD). Three factors were selected as process (independent) parameters: initial lactose concentration, temperature and inoculum concentration, while ethanol concentration was selected as response (dependent parameter).

2 Material and Methods

2.1 Microorganism and inoculum preparation

The yeast strain *Kluyveromyces fragilis* (Kf 1) used in this work was obtained from the culture collection of the Centre of Biological Engineering, University of Minho (Portugal) and maintained on YPD agar plates at 4ºC.

The inoculum culture was prepared by transferring a loopful of cells from a freshly grown culture (incubated at 30ºC for 30 h) into 500 mL Erlenmeyer flasks containing 100 mL sterile CWP solution (50 g/L lactose). Incubation was carried out on a rotary shaker (200 rpm) at 30ºC for 24 h.

2.2 Fermentation conditions

Batch experiments were performed in 500 mL Erlenmeyer flasks containing 100 mL of medium composed by CWP solution with initial pH adjusted to 5 with citric acid (1 M). The flasks were maintained in an orbital shaker at 150 rpm for 44 h. The initial lactose concentration, temperature and inoculum concentration were considered according to the experimental design showed in Table 1. All experiments were performed in duplicate.

2.3 CWP solutions preparation

Cheese whey powder (CWP) was kindly supplied by Lactogal (Porto/Portugal). Deproteinization was carried out by heat treatment (115ºC, 15 min) of acidified (pH 5) CWP solutions with different initial lactose concentrations. The precipitates were removed by centrifugation at 8500 rpm and 10ºC for 15 min and the supernatant was used as fermentation medium.

2.4 Analytical methods

The fermented media samples were centrifuged at 4000 rpm for 10 min and the supernatant was used to quantify the lactose and ethanol concentrations. Remaining solid was washed once with distilled water and centrifuged and then, diluted with distilled water for analysis of biomass. The biomass concentration was monitored spectrophotometrically at 600 nm and estimated from a biomass dry weight vs. absorbance calibration curve obtained previously. The lactose and ethanol concentrations in the supernatant were quantified by high-performance liquid chromatography (HPLC), using a Jasco chromatograph equipped with a refractive index (RI) detector (Jasco 830-RI) and a Chrompack column (300 x 6.5 mm) at 60ºC, using 5 mM sulfuric acid as the eluent at a flow rate of 0.5 mL/min and a sample volume of 20 μl.

2.5 Experimental design

In order to optimize process parameters, a central composite design (CCD) with three factors at three levels was performed. Experimental results of the CCD were fitted with a second-order polynomial equation by a multiple regression analysis. The quadratic model for predicting the optimal point was expressed as follows:

$$Y = C_0 + \sum_{i=1}^{3} C_i x_i + \sum_{i=1}^{3} C_{ii} x_i^2 + \sum_{i=1}^{3} \sum_{j<i} C_{ij} x_i x_j \quad (1)$$

where Y is the response (ethanol concentration), C_0, C_i, C_{ii}, and C_{ij} are constant coefficients, and x_i and x_j are the coded independent factors. The independent factors were coded according to the following equation:

$$x_i = \frac{X_i - X_0}{\Delta X_i} \quad (2)$$

where x_i is the coded value of the ith independent variable, Xi the real value of the ith independent variable, X_0 the original value of the ith independent variable at the center point, and ΔXi the step change value (50 for initial lactose concentration, 5 for temperature and 1 for inoculum concentration).

The quality of the fitted polynomial model was expressed by the coefficient of determination R^2, and its statistical significance was checked by the F-test. The significance of the regression coefficients was tested by t-value. Results were analyzed by the Experimental Design Module of the Statistica 5.0 software (Statsoft, USA). The model permitted evaluation of the effects of linear, quadratic and interactive terms of the independent variables on the chosen dependent variable.

3 Results and Discussion

A central composite design for the three factors (initial lactose concentration, temperature and inoculum concentration), each at three levels and three replicates at the center (to account for pure internal error), was applied for optimizing ethanol production in shake flasks. The design matrix for these factors in the optimization runs is noted in Table 1.

The results presented in Table 1 for ethanol production were subjected to analysis of regression and analysis of variance (ANOVA) (Table 2). After applying the ANOVA statistical test, it was found that, in the range studied, only the linear and quadratic effect of initial lactose concentration had a significant effect on ethanol production at 95% confidence level. The lack-of-fit test was insignificant (p = 0.066), and the regression equation obtained presented a R^2 value of 0.968 (R^2 > 0.75 indicates the aptness of the model), suggesting that a second-order model accurately represents the data in the experimental region studied, explaining 96.8% of the variability in the response. The following regression equation was obtained:

$$Y = 27.5 + 17.9\, x_1 + 3.8\, x_1^2 \quad (3)$$

where Y is the ethanol concentration (response) and x_1 is the initial lactose concentration (coded independent factor). The significance of each coefficient was determined by Student's t-test and p-values, which are listed in Table 2. The larger the magnitude of the t-value and smaller the p-value, more significant is the corresponding coefficient.

* Values significant at 95% confidence level

The relation between factors and response can best be understood by examining surface plots as a function of two factors at a time and holding the other factor at fixed level. The three-dimensional response surface curves were then plotted (Fig. 1). Figure 1 shows that increasing initial lactose concentration resulted in higher ethanol production, with maxima values (≥41.5 g/L) at maximum concentration tested (150 g/L). Previous report on ethanol production from cheese whey powder found that the ethanol concentration was proportionally increased with the increase in initial sugar concentration up to 75 g/L (Ozmihci and Kargi, 2007b). The maxima ethanol amounts produced in the present study were higher than those obtained by direct fermentation of crude (nonconcentrated) cheese whey (Zafar and Owais, 2006) or cheese whey powder (Ozmihci and Kargi, 2007b).

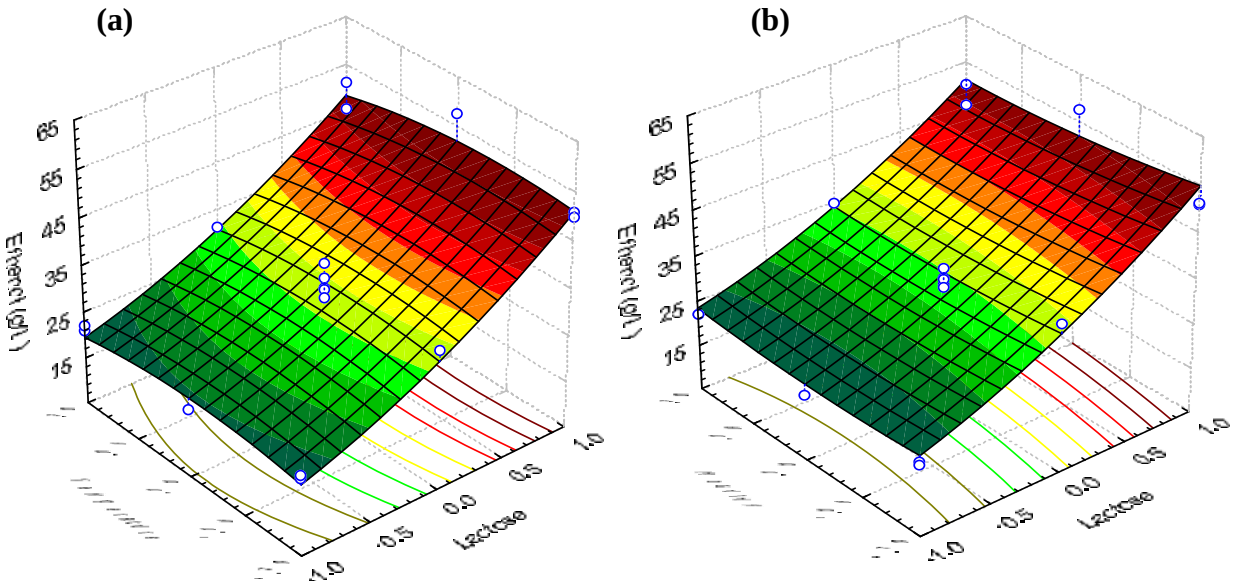

Figure 1. Response surface of ethanol production from cheese whey powder by *K. fragilis* as a function of: (a) initial lactose concentration and temperature, (b) initial lactose and inoculum concentrations.

4 Conclusions

The initial lactose concentration of cheese whey powder affected the production of ethanol by *K. fragilis* (Kf 1) (p<0.01).

The response surface analysis of the central composite design results indicated that, in the range studied, the optima conditions for maximum ethanol production (≥41.5 g/L) consisted in using an initial lactose concentration of 150 g/L, temperature between 25 and 35ºC, and inoculum concentration between 1 and 3 g/L.

The results proved the feasibility of using cheese whey powder as substrate to produce higher ethanol concentrations than those obtained by direct fermentation of nonconcentrated cheese whey.

APPLICATION OF NORMALIZED WEIBULL MODEL FOR DESCRIBING THE AIR DRYING OF MANGO SLICES AT DIFFERENT MATURITY STAGES

Otoniel Corzo[1*], Nelson Bracho[2], Carlos Alvarez[1]
[1] Department of Food Technology, Universidad de Oriente, Nucleo de Nueva Esparta. Guatamare. Venezuela.

Keywords: Moisture content, water diffusion coefficient, simulation
Topic: Multi-scale and/or multi-disciplinary approach to process-product innovation: Food Engineering.

Abstract

Application of Weibull model was investigated for describing the thin layer drying of green and half-ripe mango slices and determining the water effective diffusion coefficient (D_e), respectively. Mango fruits at green and half-ripe stages were cut into slices with an average thickness of 3.0 x10^{-3} m. The air drying was carried out at four air temperatures of 50, 60, 70 and 80 ºC and two air velocities of 1.80 and 1.91 m/s. The high regression coefficients (R^2 > 0.99), low asymptotic standard errors for derive parameters and chi-square indicated the acceptability of normalized Weibull model for determining D_e. The values of D_e ranged approximately from 1.76 x 10^{-10} to 3.14 x 10^{-10} m^2/s, and from 2.30 x 10^{-10}.

1. Introduction

Developing drying models and determining moisture transport parameters are of particular interest for efficient mass transfer analysis and reproducibility of quality-controlled products. Fick's law of diffusion, based on effective diffusivity approach, has been used to describe the moisture diffusion process for food products by many researchers. Although this model provides insights into mechanistic relevance of an observed phenomenon, it frequently sacrifices the precision of the representations due to overlooked existence of uncertainties. On the other hand, the development of empirical models requires considerably less effort. They are able to overcome any inaccuracies of mechanistic models caused by the existence of uncertainties among the empirical models. The probabilistic Weibull model has been used to describe the behavior of rehydration kinetics (García-Pascual et al., 2006), water loss during osmotic dehydration (Cunha et al., 2001), and mass transfer during vacuum osmotic dehydration (Corzo and Bracho, 2008). The Weibull distribution model is described by two parameters, the scale parameter and the shape parameter. The scale parameter (α) defines the process rate constant, and the shape parameter (β) is related to velocity of the mass transfer at the beginning. Many attempts were made in order to utilize the scale parameter of the Weibull distribution function as an indicator of the mechanism (i.e. diffusion, external resistance and matrix relaxation) of liquid uptake during rehydration. The Weibull distribution model was normalized by Marabi *et al*. (2003) to describe water uptake during rehydration of food particulates (Marabi *et al*., 2003, 2004). Internal diffusion, external resistance and relaxation processes could be described with a normalized Weibull distribution. There is little information available in the literature about using Weibull model to describe the air drying of fruit products. The objectives of this study were the determination of the applicability of normalized Weibull model in describing the thin layer drying of green and

half-ripe mango slices, and determining the water effective diffusion coefficient of mango slices.

2. Materials and methods

Sample preparation

Green and half-ripe mango fruits (*Mangifera indica*, variety Hilacha) were acquired from same crop grown in Margarita Island, Venezuela. Ten mango fruits of given maturity stage (N = 80) were used for each experimental condition. Samples were washed by a tap water, peeled and cut into slices with an average large of 45.2 $x10^{-3}$ m, average width of 34.4 $x10^{-3}$ m, and average thickness of 3.0 $x10^{-3}$ m. The determination of moisture content for fresh mango was carried out in four replicates.

Air drying

The air drier used mainly consists of three basic units, a fan providing desired drying air velocity, heat exchanger using resistance coil controlling the temperature of drying air and drying chamber. The mango slices were uniformly spread in a drying pan as thin layer. The drying experiments were carried out at air velocity of 1.80, or 1.91m/s and temperature of 50, 60, 70 or 80 ºC. The air humidity was 0.018 ± 0.001 kg/kg dry air. Changes in weight of slices were monitored at 10 min intervals by a digital balance of 0.01 g accuracy. The drying was continued until there is no large variation in the weight. Drying experiments were repeated twice.

The normalized Weibull model

The Weibull model was modified and the rate parameter was normalized with a characteristic dimension for the thickness:

$$\frac{X_w - X_{we}}{X_{w0} - X_{we}} = MR = \exp\left[-\left[\frac{t}{\alpha_n}\right]^{\beta}\right] = \exp\left[-\left[\frac{t\,D}{L^2}\right]^{\beta}\right] \quad (1)$$

where X_{wo}, X_w and X_{we} are the initial, at a time t, and at equilibrium moisture content respectively, α is the scale parameter of the Weibull model, β is the shape parameter (dimensionless), D is the calculate water diffusion coefficient, L is the half-thickness of the slices for drying from both top and bottom sides, and t is the drying time.

The effective diffusion coefficient (D_e) can be calculated by following equation:

$$D_e = \frac{D}{R_g} \quad (2)$$

where (R_g) is the geometric factor.

Simulation

To establish the adequate parameter (R_g) to be utilized for the implementation of the normalized Weibull, the solution of Fick's second law for diffusion from a flat plate have been used (Crank, 1975):

$$MR = \frac{8}{\pi^2}\sum_{n=0}^{n=\infty}\frac{1}{(2n+1)^2}\exp\left[-\frac{(2n+1)^2\,\pi^2\,D_e\,t}{L^2}\right] \quad (3)$$

In order to simulate realistic conditions, a set of random errors taken from a population with normal distribution with zero mean and different values of standard deviation (i.e., noise's span) was introduced (Azevedo *et al*., 1998):

$$MR_{noise} = MR_{theoretical}\left[1 + SD\ x\ Zn\right] \quad (4)$$

where *SD* is the standard deviation (%) and *Zn* is the random number with standard normal distribution, *Zn* ~ (0.1).The noise span of 2.5% was utilized to depict experimental error expected in air drying process.

For simulation the range of the effective diffusion coefficient was taken as 10^{-10} to 10^{-12} m^2/s describing typical values expected for dehydrated foods. The moisture ratio data at the different drying conditions were derived from simulation using the first three terms of the serie in the analytical solution of the Fickian diffusion model. Then, the normalized Weibull model was fitting to data derived from simulation and the geometric factor (R_g) was

determined.

Statistical analysis

Non linear regression using Levenberg-Marquandt method was diffusion coefficient and used for fitting experimental moisture ratio data to Esq. 1. Normalized Weibull model was used to compare predicted moisture ratio during drying to that of experimental moisture ratio data. The performance of the model was determined using the determination coefficient (R^2) of the non linear regression, and the chi-square (χ^2).

3. Results and discussion

Moisture content changes

The initial moisture content of green and half-ripe mango slices were observed to be 6.673 ± 0.112 and 6.015 ± 0.231 kg water/kg db, respectively. The equilibrium moisture content ranged from 0.136 ± 0.011 to 0.325 ± 0.018 kg water/kg db for green mango slices and from 0.105 ± 0.008 to 0.313 ± 0.016 kg water/kg db for half-ripe mango slices. An analysis of variance showed that moisture ratio decreased ($p < 0.05$) with increasing drying time and air temperature and velocity for all maturity stages. In general, towards the end of drying the influence of both air temperature and velocity on moisture ratio changes are lower than at the beginning. Similar results were found during convective drying of figs (Piga et al., 2004), plum (Goyal et al., 2007), peach (Kingsly et al., 2007) and cherry laurel (Kaya and Aydin, 2008).

Simulation

The moisture content data at the different drying conditions were derived from simulation using the first four terms of the serie in the analytical solution of the Fickian diffusion model. Results of fitting normalized Weibull model to data derived from simulation are shown in Table 1. The high coefficients of determination ($R^2 > 0.98$) and the low asymptotic standard errors (ASE) for derive parameters (D and β) indicated the goodness of fit.

Table 1. Effect of theoretical D_e on derived parameter (β) and geometric factor (R_g) of normalized Weibull model.

D_e (m^2/s)	β	ASE	R_g	R^2
1.0×10^{-10}	0.83	0.01	13.1	0.999
1.0×10^{-11}	0.80	0.01	13.2	0.997
1.0×10^{-12}	0.76	0.01	13.2	0.994

Table 1 shows that: 1) the calculate diffusion coefficient was one order of magnitude lower than used theoretical diffusion coefficient; 2) derived R_g value was maintained practically constant; and 3) β values increased with increasing the theoretical diffusion coefficient. Similar results were found for rehydration of food particulates (Marabi *et al*., 2003).

Application of normalized Weibull model

The high coefficients of determination ($R^2 > 0.99$), the low asymptotic standard errors for D and β, the low chi-square (χ^2) values (Table 2) and no pattern evident with the residuals across the range of diffusion coefficient (non shown) indicated the goodness of fit of experimental data to Eq. (1). The value of effective diffusion coefficient (D_e) was calculated by Eq. 8 using R_g equal 13.1 (Table 2). The D_e values ranged approximately from 1.76×10^{-10} to 3.14×10^{-10} m^2/s, and from 2.30×10^{-10} to 3.25×10^{-10} m^2/s for green and half-ripe mango, respectively. Similar values were finding by using Fick's second law of diffusion (Corzo *et al*. 2008). These values fell within the normally expected range of D_e (10^{-8} to 10^{-12} m^2/s) for dehydrated foods (Zogzas *et al*., 1996).

Values of β ranged from 0.76 to 0.80 and from 0.79 to 0.80 for green and half-ripe mango, respectively. The shape parameter is related to velocity of the mass transfer at the beginning, e.g., the lower is the β value, the faster the water loss rate at the beginning. Marabi *et al*. (2003) reported that the β value could be used to classify and differentiate between the various mechanisms involved during process. From the derived value of the β parameter (≈ 0.80) it follows that the mango slices followed a diffusion mechanism during air drying.

Table 2. Water effective diffusion coefficient (D_e) and shape parameter (β) of mango slices during air drying at different air velocities (V) and temperatures (T).

T (ºC)	V (m/s)	D x10^9 (m^2/s)	ASE x10^9	β	*ASE*	R^2	D_e x10^{10} (m^2/s)	χ^2

ASE = asymptotic standard error
χ^2 = chi-square

4. Conclusions

The normalized Weibull model describes the air drying of green and half-ripe mango slices at different air temperatures and velocities. Also, it allows calculates the water effective diffusion coefficient during process. The water effective diffusion coefficient values found were comparable with those obtained with Fick second law. The results of the analysis of variance test showed significant effects of air temperature and velocity on the water effective diffusion coefficient.

Key words: Midilli and Kucuk model, green and half-ripe mango slices.
Topic: Multi-scale and/or multi-disciplinary approach to process-product innovation: Food Engineering.

Abstract

An air dryer was used for thin layer drying process of green and half-ripe mango and moisture ratio at any drying time were compared by ten models (Newton, Page, Henderson and Pabis, modified Henderson and Pabis, logarithmic, two-term, two-term exponential, Wang and Singh, Verma *et al*. and Midilli and Kucuk). The Midilli and Kucuk model satisfactorily described the drying behaviour of mango slices at different maturity stages with highest R^2 values and lowest χ^2. air drying was carried out at four air temperatures of 50, 60, 70 and 80 ºC and two air velocities of 1.80 and 1.91 m/s. Temperature sensitivity of parameter *k* and *n* for green mango decreased ($p<0.05$) with increasing air velocity from 1.76 m/s to 1.80 m/s and then increased with increasing velocity to 1.91 m/s. Temperature sensitivity of parameter *k* for half-ripe mango increased ($p<0.05$) with increasing air velocity, at 1.91 m/s and was found to be the most temperature sensitive while that at 1.76 was the least temperature sensitive. Temperature sensitivity of parameter *n* for half-ripe mango increased ($p<0.05$) with increasing air velocity from 1.76 m/s to 1.80 m/s and then decreased with increasing velocity to 1.91 m/s.

1 Introduction

Thin layer drying studies form the basis of understanding the drying characteristics of food since every food is unique. Numerous mathematical models (theoretical, semi-theoretical or purely empirical) available in the literature for explaining thin layer drying characteristics of agricultural products have been used. Among semi theoretical thin layer drying models, the Newton model, the Henderson and Pabis mode, the modified Henderson and Pabis model, the Page model, the modified Page model, the logarithmic model, the two term, the two term exponential, the Verma *et al*., the Midilli and Kucuk and Singh models are used widely. Mathematical models have proved to be very useful in the design and analysis of the mass and heat transfer processes during drying. All parameters used by simulation models are directly related to the drying conditions. Little information is available about research on thin layer drying of mango in literature (Goyal *et al*., 2006). Therefore, the objectives of this study were to determining the suitable model for predicting the thin layer drying kinetics of green and half-ripe mango slices at different drying air temperature and velocity conditions, and analyze the effects of temperature and velocity on the constants of the suitable model.

2 Materials and methods

Sample preparation

Green and half-ripe mango fruits (*Mangifera indica*, variety Hilacha) were acquired from same crop grown in Margarita Island, Venezuela. Ten mango fruits of given maturity stage (N = 80) were used for each experimental condition. Samples were washed by a tap water, peeled and cut into slices with an average large of 45.2 $x10^{-3}$ m, average width of 34.4 $x10^{-3}$ m, and average thickness of 3.0 $x10^{-3}$ m. The determination of moisture content for fresh

mango was carried out in four replicates.

Air drying

The air drier used mainly consists of three basic units, a fan providing desired drying air velocity, heat exchanger using resistance coil controlling the temperature of drying air and drying chamber. The mango slices were uniformly spread in a drying pan as thin layer. The drying experiments were carried out at air velocity of 1.80, or 1.91m/s and temperature of 50, 60, 70 or 80 ºC. The air humidity was 0.018 ± 0.001 kg/kg dry air. Changes in weight of slices were monitored at 10 min intervals by a digital balance of 0.01 g accuracy. The drying was continued until there is no large variation in the weight. Drying experiments were repeated twice. This procedure was followed for each experiment corresponding to the conditions according to a 4x3x2 factorial design where the air temperature, velocity, and maturity were 50, 60, 70 and 80 ºC, 1.76, 1.80 and 1.91 m/s, and green and half-ripe mango, respectively.

Drying models

Moisture ratio of samples during drying was expressed as:

$$MR = \frac{X_t - X_e}{X_0 - X_e} \quad (1)$$

where X_t is the moisture content at any time t, X_e and X_0 are equilibrium and initial moisture contents (dry matter).

To select a suitable model for describing the drying process of mango slices, drying curves were fitted with eight theoretical and semi-theoretical models:

1. Exponential or Newton model $MR = \exp(-k\,t)$ (2)

2. Henderson and Pabis model $MR = a \exp(-k\,t)$ (3)

3. Modified Henderson and Pabis model

$$MR = a \exp(-k\,t) + b \exp(-g\,t) + c \exp(-h\,t) \quad (4)$$

4. Page model. $MR = \exp(-k\,t^n)$ (5)

5. Two term model. $MR = a \exp(-k_0\,t) + b \exp(-k_1\,t)$ (6)

6. Two term exponential model. $MR = a \exp(-k\,t) + (1-a) \exp(-k\,a\,t)$ (7)

7. Logarithmic model. $MR = a \exp(-k\,t) + c$ (8)

8. Verma et al. model. $MR = a \exp(-k\,t) + (1-a) \exp(-g\,t)$ (9)

9. Midilli and Kucuk model. $MR = a \exp(-k\,t^n) + b\,t$ (10)

10. Wang and Singh model. $MR = 1 + a\,t + b\,t^2$ (11)

where *n, a, b, c, g, h, k, k_0, and k_1* are constant of models, and *t* is the drying time.

Statistical analysis

Non linear regression using Levenberg-Marquandt method (Bates & Watts, 1988) was used to fit experimental moisture ratio data to different models. Analysis of variance was carried out to find effects ($p<0.05$) of air temperature and velocity on the constants of selected models. The different models were used to compare predicted moisture content during drying to that of experimental moisture content data. The performance of the models was determined using the coefficient of determination (R^2) of the non linear regression, and the reduced chi-square (χ^2) between the values predicted from the model and the experimental

3. Results and discussion

Evaluation of the Models

The values of coefficient of determination (R^2), and reduced chi-square (χ^2) for proposed models are presented in Table 1.For all experiments, all models gave R^2 values greater than 0.92 and low χ^2 values indicating a good fit. The results showed that highest values of R^2 and lowest values of χ^2 for both maturity stages were obtained with the Midilli and Kucuk model. Similar results were obtained by some authors on drying of fruits and vegetables (Doymaz, 2005; Akpinar, 2006; Menges and Ertekin, 2006; Togrul, 2006). The constants for Midilli and Kucuk model at different conditions and maturity stages are shown in Table 2. The analysis of variance (ANOVA) showed that constants *k*, *n* and *b* for Midilli and Kucuk model were significant different ($p<0.05$) for both maturity stages and were affected by air velocity and

temperature and its interactions

Table 1. Statistical results obtained from the proposed models for mango slices

The constants for Midilli and Kucuk model at different conditions and maturity stages are shown in Table 2. Analysis of variance (ANOVA) showed that constants *k*, *n* and *b* for Midilli and Kucuk model were significant different ($p<0.05$) for both maturity stages and were affected by air velocity and temperature and its interactions. ANOVA showed that constant *k* increased ($p<0.05$) with increasing air temperature while constant *n* decreased ($p<0.05$). There are not trends in constants *k* and *n* with increasing velocity. There are not trends in constant *b* with increasing temperature and velocity. The *k* values are higher for half-ripe mango while the *n* an *b* values are higher for green mango.

Modeling Effects of Temperature on the Midilli and Kucuk Model Constants

Dependence of the Midilli and Kucuk model constants with the temperature is represented by the Arrhenius equation:

$$A = A_0 \exp\left(-\frac{E_a}{R\,T}\right) \tag{12}$$

where A_0 is the frequency factor (min^{-1}), E_a s the activation energy (kJ/mol), R the universal gas constant (8.314 J/mol K) and T is the absolute temperature (K). Non linear regression pooling all data was applying to determine the constants and Arrhenius parameters. The results of the non-linear regression used to fitting data to Eq. (12) are shown in Table 3. The high coefficients of determination ($R^2 > 0.93$) indicate that the constants *k* and *n* of Midilli and Kucuk model as a function of air temperature followed an Arrhenius relationship for all the air velocity (Table 3). Temperature sensitivity of parameter *k* and *n* for green mango decreased ($p<0.05$) with increasing air velocity from 1.76 m/s (E_{ak} = 20.994 J/mol and E_{an} = 9,685 J/mol) to 1.80 m/s (E_{ak} = 28.656 J/mol and E_{an} = 2.188 J/mol) and then increased with increasing velocity to 1.91 m/s (E_{ak} = 20.053 J/mol and E_{an} = 7.662 J/mol). Temperature sensitivity of parameter *k* for half-ripe mango increased ($p<0.05$) with increasing air velocity, at 1.91 m/s was found to be the most temperature sensitive (E_{ak} = 29.451 kJ/mol) while that at 1.76 was the least temperature sensitive (E_{ak} = 20.451 kJ/mol). Temperature sensitivity of parameter *n* for half-ripe mango increased ($p<0.05$) with increasing air velocity from 1.76 m/s (E_{an} = 1.361 J/mol) to 1.80 m/s (E_{an} = 2.363 J/mol) and then decreased with increasing velocity to 1.91 m/s (E_{an} = 1.632 J/mol).

4. Conclusion

Acording to the results of thin layer drying of green and half-ripe mango slices, Midilli and Kucuk model could be used to predict the moisture content of the product at any time of drying process with high ability between drying air temperatures of 50 and 80 ºC and velocities of 1.76 and 1.91 m/s.

Topic: Food engineering.

Abstract

Analysis of changes in microstructure is very important in order to understand mass transfer processes in biological systems and to evaluate the quality of fresh and processed food materials. In this study, chestnuts (*Castanea sativa*) were dried by hot air at 65ºC and rehydrated at 25ºC. The cellular superficial tissue of fresh and processed chestnut at different moisture contents was characterized by optical microscopy. The results show that during drying the size of chestnut cells decreased and shape was changed. During rehydration the cells recoved size and the most of shape parameters.

1. Introduction

Food processing involves different operations such as dehydration and rehydration that involve changes in the structural characteristics of the cell tissue. These changes are directly related to heat and mass transfer gradients that take place during these processes (Prothon et al., 2001). The type and magnitude of these gradients depend on the process conditions and dehydration technique (convective, osmo-convective, freeze drying, etc). Microscopy techniques (optical, scanning electron, transmission electron) are important visualization tools of the cell structure and therefore, are used to improve the knowledge of the dehydration and rehydration processes (Aguilera and Stanley, 1999). Optical microscopy is a simple technique that allows the observation of the presence of damages on the cell tissue.

The main aim of this work is to characterize the cell tissue of fresh chestnut (no data can be found in the bibliography) and, additionally, monitoring the changes in size and shape of chestnut cells during drying and rehydration processes.

2. Materials and Methods

Experiments of optical microscopy have been carried out with cell tissue of chestnuts at different moisture contents: fresh, dried and rehydrated. Experimental conditions during convective drying were at 65 ºC and 30 % of relative humidity at different times. After drying, samples of chestnuts were rehydrated employing distilled water at 25 ºC during different times. In order to visualize cells by microscopy, thin slabs were cut using a razor blade. These samples were put on a thin glass plate under the objective (10x). One side of the slab was stained with toluidine solution (0.1 % during 15 s). In this way, samples were ready for observation under the light microscope (Zeizz Axioskop 40). A digital camera (Nikon D70) was attached to the microscope to take images of cells structures and transfer them to a computer. Images were calibrated with a micrometer of 10 mm length and divisions of 0.1 mm interval (Zeiss). The images were analysed using “Image Tool” (free software available from University of Texas). Several geometrical parameters (area, external perimeter, Feret diameter, roundness,

* Corresponding author. Tel + 34-981-563-100. E-mail:eqmoncho@usc.es

elongation and compactness) of cells were determined. These parameters were previously considered by other authors for other food materials (Reeve, 1953; Lewicki and Pawlak, 2003; Mayor et al., 2005).

3. Results

Figure 1 shows a image of the microstructure of chestnut superficial cellular tissue. As can be observed, the cells present different sizes and shapes. Some of them are round, others more elongated or polygonal. It can be observed the presence of intercellular spaces, which contain the gas phase of the tissue and some of them can be filled with and aqueous solution.

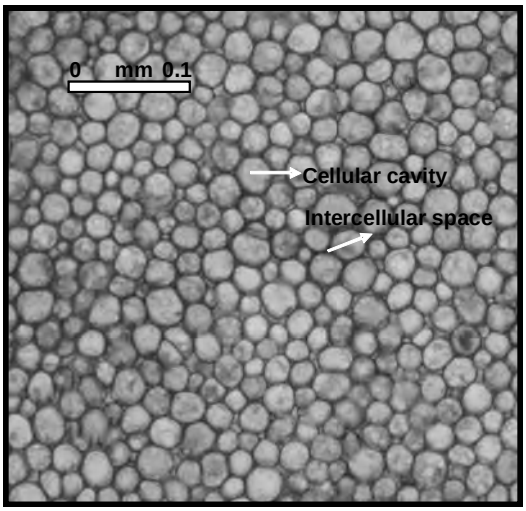

Figure 1 Microscopy image of fresh chestnut cellular tissue

Table 1 shows average values, corresponding deviations and the range of experimental data for the geometric parameters obtained from fresh samples. The characterization of the size and shape parameters for cells of fresh chestnuts with different ripeness was developed analysing more than 500 cells and the results indicated that values vary in a wide range. Average area value (876 μm^2) was less than values obtained for other products, such as apple and pumpkin (Lewicki y Porzecka-Pawlak, 2005; Mayor et al., 2005). By other hand, in the case of shape parameters the range was similar to pumpkin cells.

Table 1 Size and shape parameters for fresh chestnut cells.

Parameters	Average	Range
Area (10^{-3} mm^2)	0.8761 ± 0.0311	0.5000-1.9500
Perimeter (mm)	0.1394 ± 0.0280	0.0841-0.2009
Feret diameter (mm)	0.0329 ± 0.0057	0.0232-0.0571
Elongation	1.2311 ± 0.1369	1.0067-1.6793
Roundness	0.5736 ± 0.1656	0.1977-0.8755
Compactness	0.8499 ± 0.0632	0.6066-0.9585

The size distribution of fresh chestnuts cells can be observed in Figure 2 and showed the highest quantity (74 %) was in the range from 500 to 1050 μm^2.

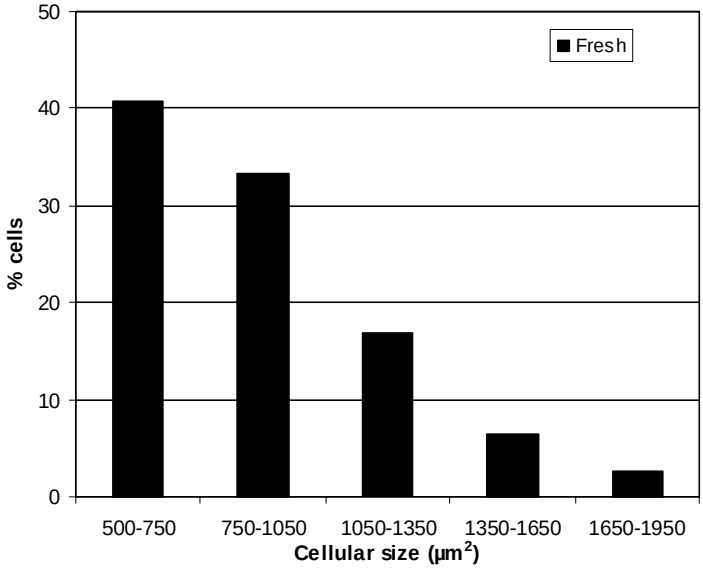

Figure 2 Cell size distribution of fresh chestnuts

Figure 3 shows images of cell tissue of the same sample of chestnut, selected as example, obtained by microscopy during diferent convective drying times at 65 ºC. The fresh chestnut cells (Figure 3a) are larger and with high values of roundnes than drying chestnuts during 0.5, 1.5 and 4 hours (Figure 3b,c,d). By other hand, chestnut structure does not present significant changes like internal ruptures and shrinkage that were found during drying of carrot (Kerdpiboon and Devahastin, 2007), red pepper (Vega-Gálvez et al., 2008) and apple (Mayor et al., 2005).

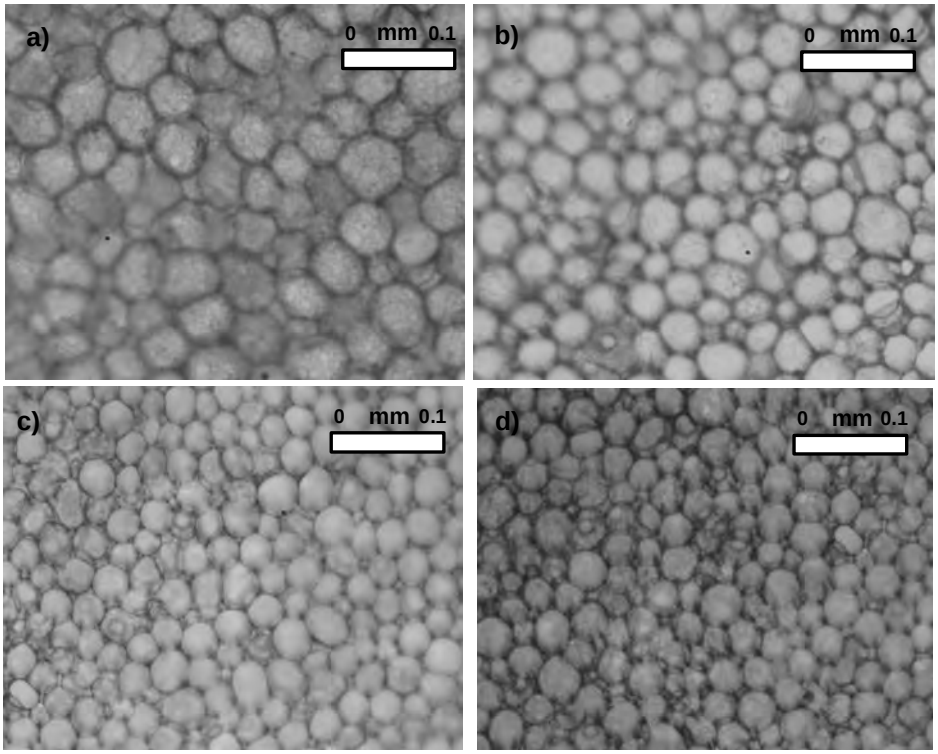

Figure 3 Cells of chestnut tissue after drying at 65 ºC: a) 0h; b) 0.5h; c) 1.5; d) 4h

The results obtained of size distribution of chestnuts cell during drying process can be observed in Figure 4. The results showed a relevant increase (from 0 to 62 %) in the minor size range (from 100 to 400 μm^2) and the cells population corresponding to the largest sizes (from 750 to 1350 μm^2) decreased (from 35 to 18 %) (Figure 4a,d). The changes were more important during first hours (0.5 and 1.5 h) (Figure 4b,c), period in which drying rates are also higher.

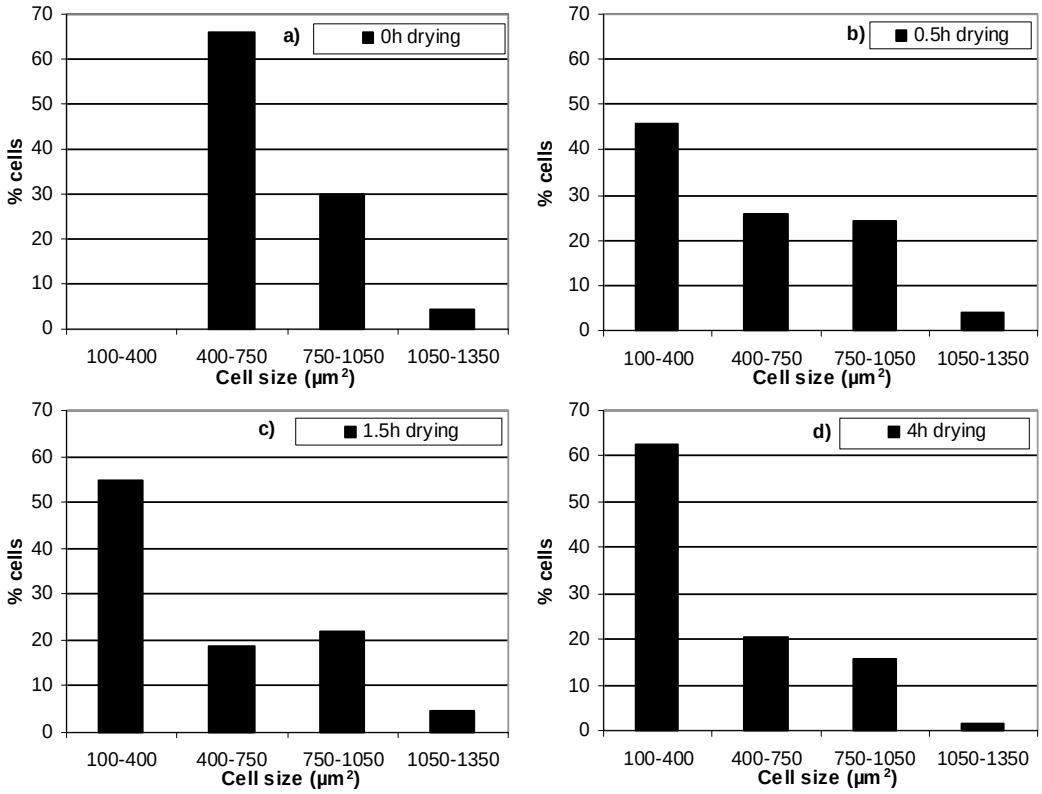

Figure 4 Chestnut cells size distribution after drying at 65ºC: a) 0h; b) 0.5h; c) 1.5; d) 4h

Concerning chestnut cell size parameters, these values reduced with drying time. After 1.5h of process, values of area, perimeter and Feret diameter did not change significantly regard as chestnuts dried until 4h. Cellular shape changed during drying and these parameters are shown in Table 2. The cells roundness and compactness decreased and became more elongated (typical behaviour of cells during food materials drying).

Table 2 Chestnut cell shape parameters after drying at 65 ºC

t (h)	Average	Range
	Elongation	
0	1.2324 ± 0.1624	1.1072-1.5760
0.5	1.2892 ± 0.2133	1.0242-2.1849
1.5	1.4124 ± 0.1950	1.0746-1.8590

1.5	0.7888 ± 0.0787	0.5797-0.8929
4	0.7058 ± 0.0951	0.4952-0.8455

Figure 5 shows images of cell tissue obtained by microscopy of chestnut that was previously dried at 65 ºC until 4 h and after rehydrated during diferent times at 25 ºC. The images of surface cells during rehydration indicated that size increases strongly in a short period of time.

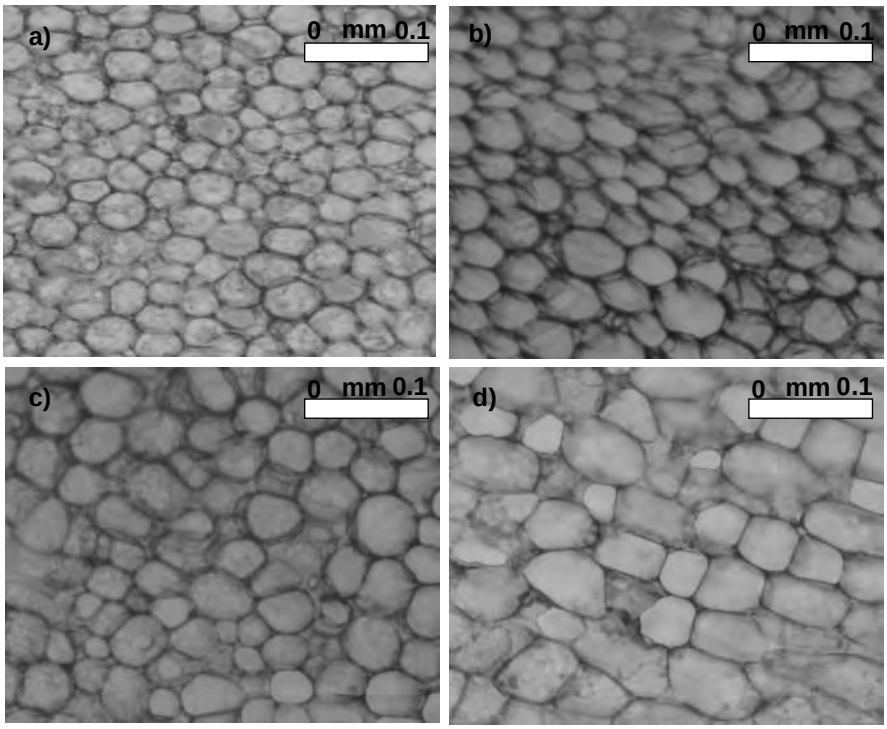

Figure 5 Cells of chestnut tissue after rehydration at 25 ºC: a) 10min; b) 30 min; c) 60 min; d) 120 min

Figure 6 shows the corresponding distribution cell size during rehydration of chestnuts. The relative population of smaller cells (from 100 to 750 μm^2) decreased and population (from 1050 to 2350 μm^2) corresponding to larger sizes increased during rehydration process. A great number of cells achieved size values higher than the corresponding cells of fresh chestnut.

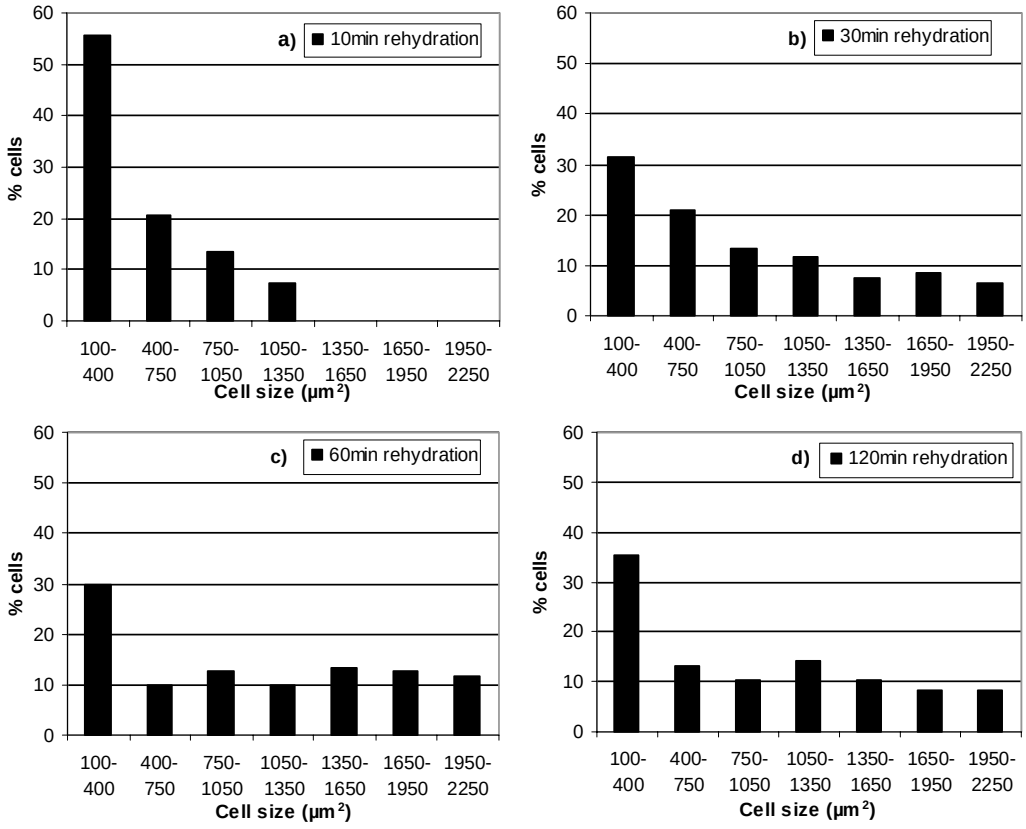

Figure 6 Chestnut cell size distribution after rehydration at 25ºC a) 10min; b) 30min; c) 60min; d) 120min

The size parameters (area, perimeter and Feret diameter) after 30 minutes at 25 ºC were similar to the corresponding of fresh chestnut. Table 3 shows shape parameters (elongation, roundness and compactness) during rehydration time. Elongation decreases, roundness and compactness parameters increase up to 10 min of rehydration. These parameters became constants after this time. Shape parameters were slightly lower than fresh chestnuts at the end of rehydration process.

120	0.7705 ± 0.0724	0.4945-0.8677

4. Conclusions

Changes in size and shape of chestnut cells were determined during drying and rehydration processes. Shrinkage and swelling of cells were observed during both processes being recovered the fresh samples values of size, roundness and elongation after rehydration. Finally, these results indicate that the analysis by microscopy is an interesting tool to link macroscopic processes with microscopic phenomena and to improve the knowledge of mass transfer processes in cellular tissues.

Topic: Integration of life sciences & engineering

Abstract

Amanita ponderosa strains are wild mushroom, edible, with a high exportation potential. This specie grows spontaneously in some microclimates in Iberian Peninsula, due to its Mediterranean characteristics, namely in Alentejo and Andaluzia. Due to the great diversity of wild mushrooms, it is essential be able to differentiate and identify the several edible mushrooms species. RAPD markers have been used as a valuable tool to distinguish different genotypes in edible mushrooms; however, it's a new approach, for *Amanita ponderosa* strains.

In the present study six *Amanita ponderosa* strains were compared with others Basidiomycetes (*Pleurotus ostreatus*, *Lactarius deliciosus* and *Coriolus versicolor*) and one Ascomycete strain (*Tuber* sp.) in order to establish different genetic fingerprintings profiles between strains.

Molecular profiles were analyzed by RAPD-PCR using eight micosatelites primers and by MSP-PCR using the M13. Results showed that different patterns were generated for each nine strains tested. RAPD analysis enabled to differentiate at species and strain level, however, the degree of discrimination by means of RAPD-PCR depends highly on the primers used. The MSP-PCR is a fast method to amplified DNA polymorphic sequences, with high reproducibility and similarity for the same specie that allow to characterise the genetic profile of the edible mushrooms *Tuber* sp., *Lactarius deliciosus*, *Pleurotus ostreatus* and *Amanita ponderosa*. Moreover, constitute a valuable tool to distinguish the different genotypes of *Amanita ponderosa* strains, allowing to identify at specie level and to differentiate *A. ponderosa* strains from each origin sites.

1. Introduction

Mushrooms are exhaustively known for its high nutritive value, gastronomic and medicinal proprieties. Consequently, the consumption of the eatable mushroom comes increasing. Most *Amanita* species are obligatorily ectomycorrhizal and play a significant role in forest ecosystems.

The south of Portugal, due to its climatic conditions and flora diversity, is one of the European regions with a high predominance of wild edible mushrooms *Amanita ponderosa*, specie with great gastronomic relevance because of their high consumption by the rural population and their economic value in the gourmet markets, of Spain and Portugal. A profound knowledge is therefore required for this specie, only few studies are described in the literature, relating mineral content (Moreno-Rojas *et al*., 2004) and molecular phylogenetic analysis (Moreno *et al*., 2008). Genetic profiles and polymorphic sequences can constitute important tools for a fast and effective characterization, namely in certification processes. Literature related a range of molecular approach based on RAPD and ITS

analyses in order to characterize and identified edible mushrooms (Moncalvo *et al*., 2000; Firenzuoli *et al*., 2007; Pacioni *et al*., 2007; Ro *et al*., 2007), MSP-PCR fingerprinting was also used to study genetic variability in yeasts and filamentous fungi species (Godoy *et al*., 2004; Alves *et al*., 2007; Lopes *et al*., 2007), showing that these methodologies have a great potential as diagnostic tools. However a lack of information to *A. ponderosa* mushrooms is verified, only one study is reported to distinguish *A. curtipes* and *A. ponderosa* species sequencing the D1-D2 domains of the 28S rRNA gene and ITS1-5.8S-ITS2 region (Moreno *et al*., 2008).

The aim of this study is to characterise *A. ponderosa* mushrooms with molecular biomarkers, by RAPD and MSP-PCR, in order to establish different genetic profiles, between wild edible mushrooms. This work is a new approach for the *A. ponderosa* species from Portugal, since until now any study was performed concerning molecular identification of these specie.

2. Material and Methods

Samples

Fruiting bodies of the *Amanita ponderosa* mushrooms were collected in Spring from 6 different locations area, in the southwest of the Iberian Peninsula, namely Évora, Beja, Mina de São Domingos, Santo Aleixo da Restauração and Vila Nova de São Bento (Alentejo, Portugal) and from Cabeza Rubia (Andalusia, Spain). For the molecular study, the *A. ponderosa* strains were compared with others Basidiomycetes (*Pleurotus ostreatus* and *Lactarius deliciosus*) and with one Ascomycete strain (*Tuber sp*.). The mushrooms are deposited in Biotechnology Laboratory, Chemistry Department, University of Évora (Portugal).

Molecular analyses

The genomic DNA extraction from the small fragments of fruiting bodies was performed by the modified microsfers method (Sambrook *et al*., 1989; Martins, 2004).

DNA was quantified and diluted to a final value of 0,1 ng/L for PCR assays. The RAPD-PCR was performed with the microsatellite primers OPF-1 (5'-ACGGATCCTG-3'); OPF-6 (5'-GGGAATTCGG-3'); OPF-9 (5'-CCAAGCTTCC-3'); OPF-13 (5'-GGCTGCAGAA-3'); OPG-2 (5'-GGCACTGAGG-3'); OPG-3 (5'-GAGCCCTCCA-3'); OPH-2 (5'-TCGGACGTGA-3'); OPH-4 (5'-GGAAGTCGCC-3'). The M13 primer (5'- GAGGGTGGCGGTTCT-3') were used for MSP-PCR. The PCR conditions consisted of an initial denaturing step of 5 min at 94 ºC followed by 40 cycles of 1 min at 94 ºC, 1 min at 50°C and 72 ºC for 1 min. The reaction was completed with a final extension at 72 ºC for 5 min and then cooled and held at 4 ºC. PCR samples were separated in a 1.5% agarose gel and visualized on a UV transilluminator (Bio-Rad) using the Quantity One 1-D Analysis software (Biorad).

Statistical analysis

Phylogenetic tree was generated by UPGMA method, using the Dice coefficient of similarity, based on the fingerprinting profile of *A. ponderosa* and other Basidiomycetes and Ascomycetes strains.

3. Results and Discussion

Fruiting bodies of the *Amanita ponderosa* mushrooms were collected since February to April 2007 in the region of Évora, Beja, Mina de São Domingos, Santo Aleixo da Restauração and Vila Nova de São Bento (Alentejo, Portugal) and from Cabeza Rubia (Andalusia, Spain).

Samples were collected in different sites, growing on acidic soils in forests of *Quercus ilex* ssp. ballota and *Cistus ladanifer* and *C. laurifolius*. *A. ponderosa* mushrooms analysed were obtained in the same development stage to eliminate the interference of size. *A. ponderosa* is

A - Young mushrooms.
B - Mushrooms in maturity.

characterized by large and robust basidiomata, with a cap 8–17 cm in diameter, with a hemispheric morphology when young and plane-convex in maturity, with a slight depression in the centre (Fig. 1).

Molecular fingerprinting profile of six *A. ponderosa* strains was compared with other edible mushrooms: *Pleurotus ostreatus*, *Lactarius deliciosus* and *Tuber* sp. It is important to emphasize that our aim was not to screening pathogenic species of the genus *Amanita*, indeed several studies are reported for the detection and quantification of toxins, but to provide a rapid method to screening enable strains, namely the Mediterranean specie *A. ponderosa*.

Fig. 2 shows the fingerprinting profiles obtained by RAPD-PCR using OPF-1, OPF-6, OPF-9, OPF-13, OPG-2, OPG-3, OPH-2, OPH-4 and by M13 primer. Table 1 summarizes the band profile obtained in this study. Results showed that different patterns were generated for each ten strains tested. RAPD assays have produced polymorphism in all the studded strains, except for *C. versicolor*, showing 2-14 bands ranging from 0.1 to 2.4 kb. The amplification using M13 primer has generated a profile with 9-20 bands ranging from 0.2 to 1.3 kb.

Among all RAPD primers tested, the OPF-6, OPG-2 and OPG-3 allow to distinguish the Basidiomycetes than Ascomycetes strains, presenting clusters, for all Basidiomycetes, with a similarity of 30%, 25% and 20% respectively. The fingerprinting profile obtained with M13 primer also allowed differentiate *Tuber* sp. from the studied Basiodiomycetes with 44% of similarity. That is coherent, once *Tuber* sp. is ectomycorrhizal ascomycetes that produce subterranean ascomata known as truffles, while all other studied strains were basidiomycetes. OPF-6, OPG-2 and OPG-3 RAPD markers and M13-PCR allowed differentiate at specie and strain level. However, the degree of discrimination by RAPD-PCR depends highly on the primers used, generating different fingerprintings profiles. *A. ponderosa* strains formed clusters with 65% of similarity for OPF-6 and OPG-2 primers and 80% of similarity with OPG-3 primer. In M13-PCR fingerprinting profile, *A. ponderosa* strains were grouped in a cluster with a similarity of 67% (Figure 3).

RAPD analyses have been used as a valuable tool to distinguish different genotypes in edible mushrooms such as *Ganoderma lucidum* (Hseu *et al.*, 1996), *Lentinula edodes* (Zhang and Molina, 1995), *Agaricus bisporus* (Khush *et al.*, 1992) and *Pleurotus ostreatus* (Lee *et al.*, 2000) and to evaluate the genetic similarities (Andrade *et al.*, 2006). However, it's a new approach, for *Amanita ponderosa* strains. The second fingerprinting approach, using the minisatelite M13 makes use of the occurrence of high copy numbers of interspersed repeats motifs in most genomes, and has been used successfully to amplify hypervariable repetitive DNA sequences with high reprodutibility (Martin *et al.*, 1998; Lopes *et al*., 2007).

In this study, MSP-PCR has been used as a fast method to amplify DNA polymorphic sequences, with high reproducibility and similarity for the same specie that allow to characterise the genetic profile of the edible mushrooms *Tuber* sp., *Lactarius deliciosus*, *Pleurotus ostreatus* and *Amanita ponderosa*. Moreover, constitute a valuable tool to distinguish the different genotypes of *Amanita ponderosa* strains, allowing to identify at specie level and to differentiate *A. ponderosa* strains from each origin sites.

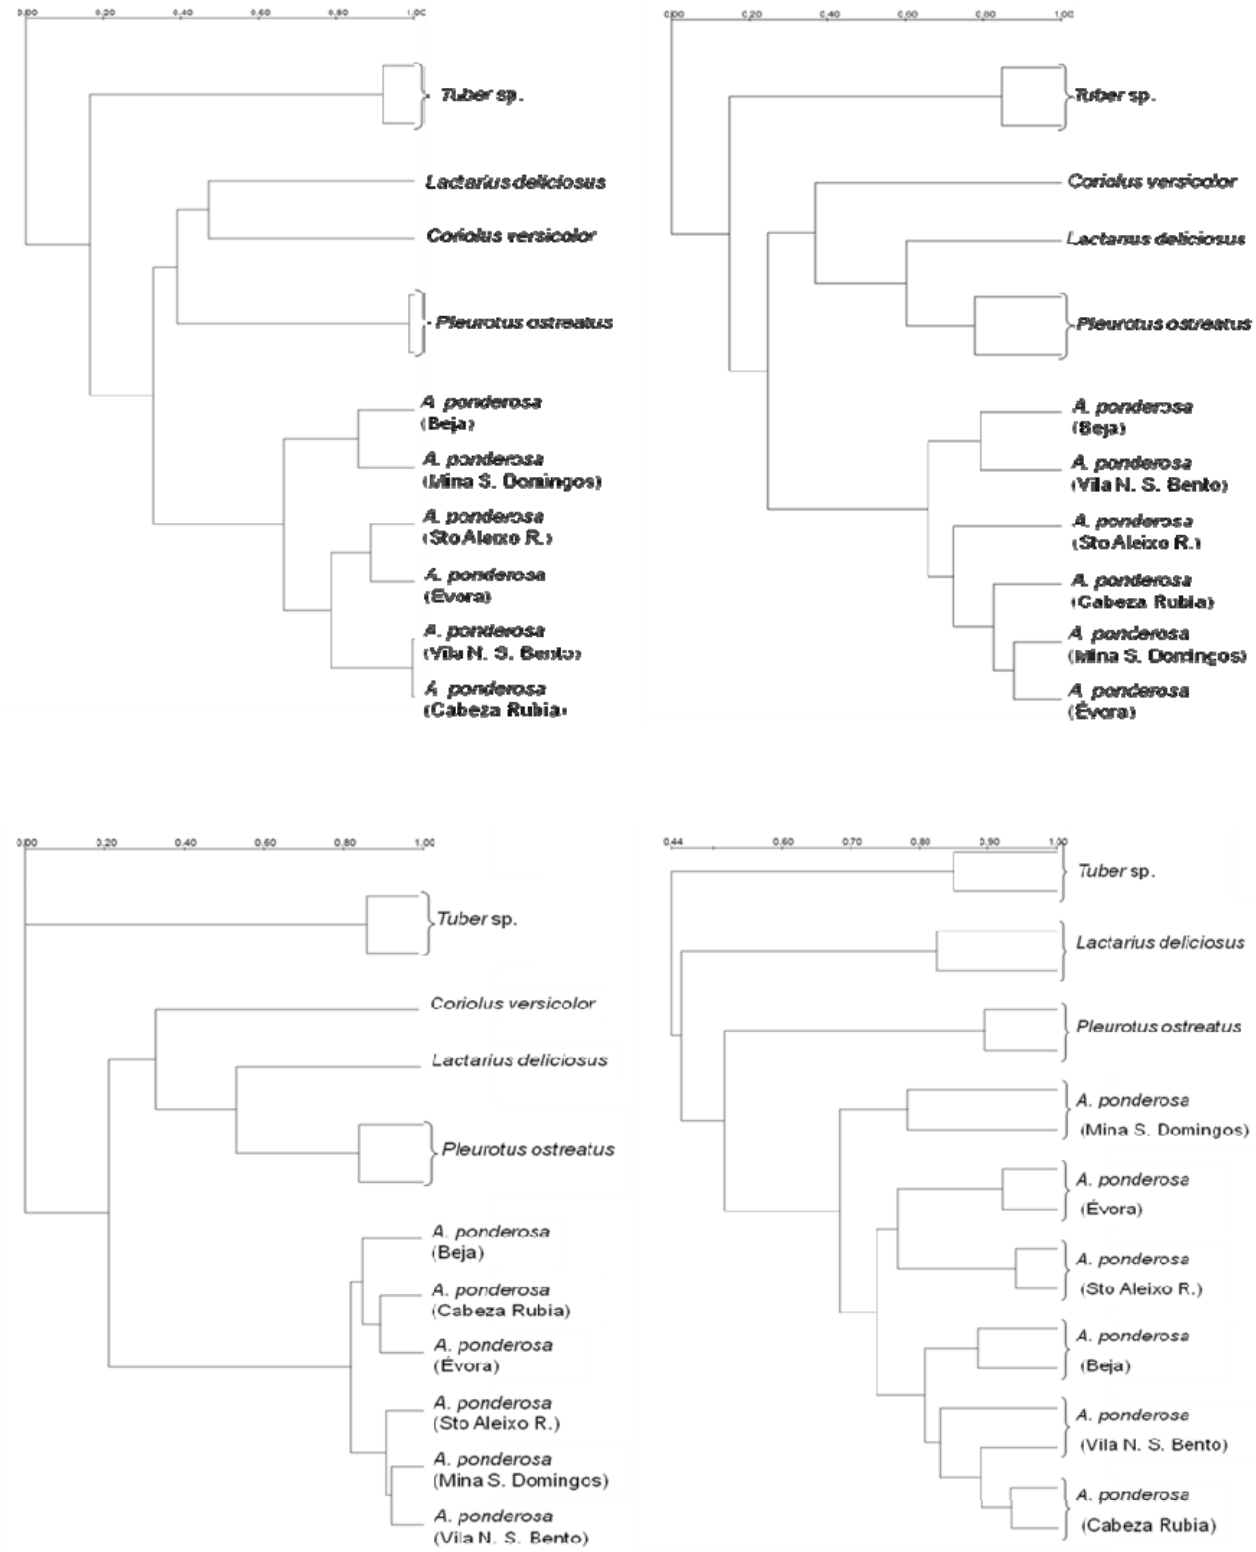

Figure 3- Dendogram analysis based on the RAPD- PCR using OPF6, OPG2 and OPG3 and M13-PCR fingerprinting patterns for different strains of *A. ponderosa* and for *L. deliciosus*, *P. ostreatus* and *Tuber* sp. The distance values between branches are reported as percentage of similarity (0– 100%).

In conclusion RAPD-PCR and MSP-PCR analysis establish different genetic profiles between *Tuber sp., P. ostreatus, L. deliciosus* and *A. ponderosa* strains. Additionally, the amplified DNA polymorphic sequences using OPF-6, OPG-2, OPG-3 and M13 primers allowed differentiate *Amanita ponderosa* strains collected from the different places. For maximum discriminatory power of these types of fungi, both methods RAPD-PCR and MSP-PCR should be used to categorize wild edibles mushrooms species usually found in Mediterranean ecosystems. Results clearly showed that the geographical collecting site influences the molecular fingerprint profile of *A. ponderosa strains*. A greater number of wild enable mushrooms should be analysed more often in Alentejo region (Portugal) with respect to molecular characterization.

Keywords: Reversed micelles, *Pseudomonas aeruginosa* amidases; acetohydroxamic acid; water content; stability.
Topic: Advancing the chemical and biological engineering fundamentals

Abstract

The present work involves the entrapment of either cell-free extract or whole cells from both *Pseudomonas aeruginosa* L10 and AI3 in a reversed micellar system composed of cationic surfactant tetradecyltrimethyl ammonium bromide (TTAB) in heptane/octanol (80/20%). The reaction used to study the effect of the encapsulation was a transamidation reaction catalysed by the enzyme amidase (E.C. 3.5.1.4) which is expressed by both bacteria. The effect of micellar water content (w_0) in the enzyme activity was also evaluated. The results demonstrated a major increase in the activity of acetohydroxamic acid synthesis in reverse micelles when compared with the conventional aqueous system. Furthermore when micelles water content was changed a bell-shaped profile was obtained for amidase specific activity in both cell-free extract and whole cells with a maximum activity exhibited at ω_0 =10. The study of storage stability of whole cell and cell free extract when entrapped in reverse micelles at 24ºC revealed a half-life of respectively 17 days and 26 days for *Pseudomonas aeruginosa* AI3 strain and 11 days and 8.5 days for *Pseudomonas aeruginosa* L10.

1-Introduction

Aliphatic amidases (E.C. 3.5.1.4) catalyse the hydrolysis of amide bonds in small aliphatic amides. As can be seen in Figure 1 this enzyme has also the capacity to catalyse the transfer of acyl groups to amines what enlarged the possibility of synthesising different compounds with amide bonds in a transamination reaction (Pacheco *et al*, 2005 a). Hydroxamic acid derivatives, with the general formula R–CO–NHOH, are products of transamidation reaction when the acyl acceptor is hydroxylamine.

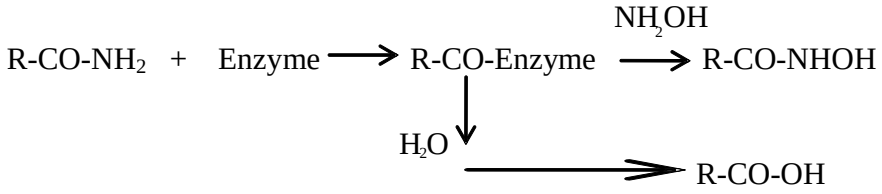

Figure 1-Aliphatic amidase catalyses the hydrolysis and transamidation reactions of amides.

* Rita Pacheco. Tel +351-21-8317000 ext. 1229 . E-mail: rpacheco@deq.isel.ipl.pt

Amidases which we are in concern have been isolated mainly from wild-type *Pseudomonas aeruginosa* 8602 but the use of mutagenic agents has allowed the isolation of several constitutive mutants producers of amidases such as L10 and AI3 (Domingos *et al* 1989). Although mutant L10 strain exhibited no difference in substrate specificity compared with wild-type amidase, in mutant strain AI3, the *amiE* gene mutation T103I is responsible for the amidase activity towards *p*-nitroacetanilide and acetamide (Karmali *et al* 2001).

Amidase from *Pseudomonas aeruginosa* has been used for studying the hydrolysis and synthesis of several compounds either in conventional medium (Pacheco *et al* 2005 a), or with reverse micelles for the synthesis of acetohydroxamic acid (Pacheco *et al*, 2005 b). These hydroxamic acids derivatives have a wide spectrum of application Hydroxamic acids are chelating agents which are known to inhibit enzymes often associated to several human diseases. These compounds are used in a number of applications since they are constituents of growth factors, antibiotics, antibiotic antagonists, tumor inhibitors and antifungal agents. On the other hand, hydroxamic acids can also be applied in food industry and waste-water treatment. (Fournaud *et al.* 1998).

Reverse micelles are spherical waterdroplets surrounded by one layer of closely packed surfactant molecules dispersed in a solvent of low polarity. The polar heads of the surfactant are in contact with only a few water molecules in the interior of the micelle and the surfactant hydrophobic tails are in contact with the surrounding organic solvent (Gómez –Puyou *et al*, 2007). Regarding the reaction scheme showed in Figure 1 the amidase transamidation reaction could be successfully performed comparatively to the hydrolysis reaction at low water content. Hence a reversed micellar system is a medium containing organic solvents with reduced quantity of water appropriate to such synthesis.

In this work *Pseudomonas aeruginosa* whole cells and cell free extract of strains L10 and AI3 containing amidase were encapsulated in reverse micelles of the cationic surfactant tetradecyltrimethyl ammonium bromide (TTAB) dissolved in heptane/octanol (80/20 %). The effect of the water content of the system on the amidase acetohydroxamic acid activity was analysed and compared with the reaction in aqueous solution. Moreover results on the whole cell and cell free extract storage stability when encapsulated in such conditions are shown in order to demonstrate the potential of such immobilization systems in numerous applications.

2-Materials and methods

Bacterial strain

Pseudomonas aeruginosa L10 and AI3 were used as the source of amidase (Domingos *et al* 1989).

Cell and cell free extract production

Pseudomonas aeruginosa strains were grown as described previously (Karmali *et al* 2001; Brown and Clarke 1972). The cell culture was harvested by centrifugation when absorbance at 600 nm was approximately 1. Cell pellet was washed twice, centrifuged and stored at .-20ºC. Frozen cells of each strain were suspended in 2 volumes of 20mM Tris-HCl buffer, pH 7.2 containing 1mM β-mercaptoethanol, 1mM EDTA, 10% V/V glycerol and 1 mM benzamidine (TMEGB buffer). Part of this suspension was used as the source of amidase and represents the whole cell of each strain. The remaining cell suspension was broken by sonication five times at 150 W for 20 s in an ice bath and centrifuged at 13400 rpm for 30 min at 4ºC, the supernatant was used as the source of amidase and represents the cell free extract of each strain.

* Rita Pacheco. Tel +351-21-8317000 ext. 1229 . E-mail: rpacheco@deq.isel.ipl.pt

Protein concentration was determined by the Coomassie blue dye binding method (Bradford, 1976) for the whole cells and cell free extract samples of each strain.

Reversed micellar system

The reverse micellar system was prepared by injecting hydroxylamine 15 mM and 30 µl of whole cell or cell free extract in TMEGB buffer into a solution of 200 mM tetradecyltrimethyl ammonium bromide (TTAB) in heptane/octanol (80/20 % v/v) under constant agitation.

Acetamide in TMEG buffer (20 mM Tris buffer pH 7.2 containing 1mM EDTA, 1mM β-mercaptoethanol, 10% glycerol) was injected to initiate the reaction in order to give a final concentration of 7.5 mM in the reverse micelles solution. The water content in the system, usually defined through the parameter w_0 = $[H_2O]/[surfactant]$ was controlled by adjusting the TMEG buffer volumes added in order to be established in the range of 3.5 to 11.5.

Analysis of storage stability for each strain whole cell and cell free extract when encapsulated was determined in a reversed micellar system prepared by injecting solely whole cell or cell free extract into a solution of 200 mM TTAB in heptane/octanol (80/20 % v/v) and the w_0 kept to a final value of 10 by adjusting the TMEG buffer volume added. This mixture was left at 24ºC during several days. Amidase activity was determined during this period, at several time intervals, by injecting to aliquots of this mixture hydroxylamine 15 mM and acetamide 7.5 mM in TMEG buffer in order to initiate the reaction.

Enzymatic activity

The amidase transferase activity associated to whole cell or cell free extract inside the reverse micelles and in aqueous solution were determined using a modification of the method developed by Brammar and Clarke (1964) using a solution of $FeCl_3$ 6% (w/v) in HCl 2%(w/v). The amidase activity was followed by measuring the formation of acetohydroxamic acid, using acetamide and hydroxylamine as substrates. The synthesis of acetohydroxamic acid was detected by formation of a brown colour complex, which absorbs at 490 nm, when adding to the reaction mixture two volumes of $FeCl_3$ 6% (w/v) in HCl 2%(w/v) solution at several time intervals during the reaction.

A calibration curve was produced for determining both concentration of hydroxamic acid inside reverse micelles and in aqueous solution at each time interval in the reaction mixture. For these calibration curves values of 0.021 $mM^{-1}cm^{-1}$(R^2= 0.9971) and 0.0889 $mM^{-1}cm^{-1}$(R^2= 0.9936) were obtained for the extinction coefficient ε, respectively, for aqueous solution and reverse micelles.

A unit of enzymatic activity (U) is defined as the amount of enzyme required to form 1 µmol acid acetohydroxamic per minute under the conditions of the reaction.

3-Results and discussion

Whole cells or cell free extract *Pseudomonas aeruginosa* L10 and AI3 were used as the source of amidase and encapsulated in a reversed micellar system of TTAB in heptane/octanol. The effect of water content w_0 was evaluated in a range from 3.5 to 11.5 by measuring amidase activity of acetohydroxamic acid synthesis resulting from a transamidation reaction.

* Rita Pacheco. Tel +351-21-8317000 ext. 1229 . E-mail: rpacheco@deq.isel.ipl.pt

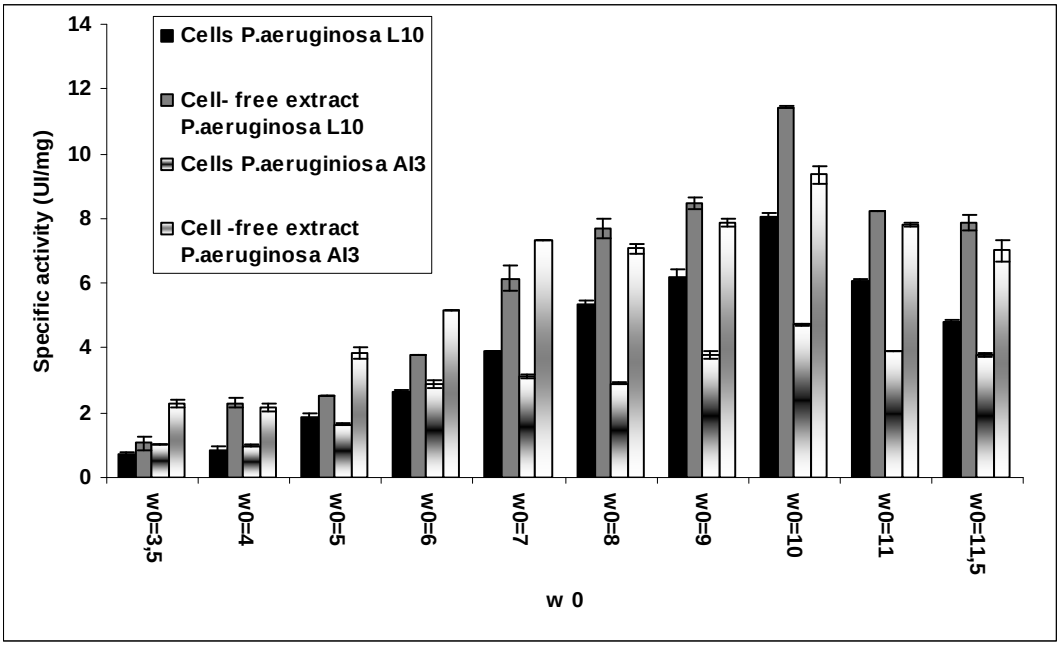

Figure 2- Influence of water content in acetohydroxamic acid synthesis for both strains

The obtain results are shown in Figure 2 and reveal a bell shape profile with a maximum in amidase activity obtained for $w_0 = 10$ in both strains. The water content of the micelles is often associated to the variation in the micelle diameter which will lead to a condition more favourable to the fitting of the enzyme inside this structure and affecting its activity (Biasutti *et all* 2008).Work is already in progress in order to evaluate the micelle internal diameter by Light Scattering and to associate such variations with amidase structure analyzed by FTIR.

As can be also seen from Figure the highest amidase activity was obtained for *P.aeruginosa* L10 cell free extract. A similar situation was also found for *P. aeruginosa* AI3 cell free extract when compared with the strain whole cells. Such difference is probably due to different diffusional resistances which occur on the transportation of the substrates from the micro environment inside the micells to the enzyme catalitic centre (Cabral *et al* 2003). This effect is much more noticeable in whole cells that in cell-free extract since in the former the biocatalyst is shielded inside the bacteria cell. Nevertheless whole cells can be also be successfully used in acetohydroxamic acid synthesis inside reversed micelles. Results shown in Figure 3 illustrate the fact that for such reaction when performed in conventional aqueous media the enzyme specific activity is considerably lower than in reversed micelles presumably due to the elevated content of water in the medium which favours the amidase hydrolysis reaction. These results are according to the literature (Pacheco *et al*, 2005 b).

The effect of encapsulation of whole cells and cell free extract on the amidase storage stability at 24ºC was analysed and results are presented in Figure 4. This analysis has as main objective to determine the amidase half life when encapsulated. Such parameter becomes extremely important when considering the significance of enzymes as biocatalysts in several industrial processes. As can be observed in Figure 4 both strains whole cells and cell-free extract exhibit the same progression profile of decrease in enzyme activity over time. Inactivation constant (k) were determined for whole cells and cell free extract and the results were respectively 0.0017 and 0.0011 h^{-1} for whole

* Rita Pacheco. Tel +351-21-8317000 ext. 1229 . E-mail: rpacheco@deq.isel.ipl.pt

cells and cell-free extract of *P. aeruginosa* AI3 and 0.0027 and 0.0034 h^{-1} for whole cells and cell-free extract of *P. aeruginosa* L10. As amidase half life ($t_{1/2}$) is concern the results were 17 and 26 days for whole cells and cell-free extract of *P. aeruginosa* AI3 and 11 and 8.5 days for whole cells and cell-free extract of *P.aeruginosa* L10 respectively. Such results demonstrate that althoug *Pseudomonas aeruginosa* L10 had overall a higher amidase specific activity is has lower storage stability than *P.aeruginosa* AI3 which makes it suitable for more robust industrial applications.

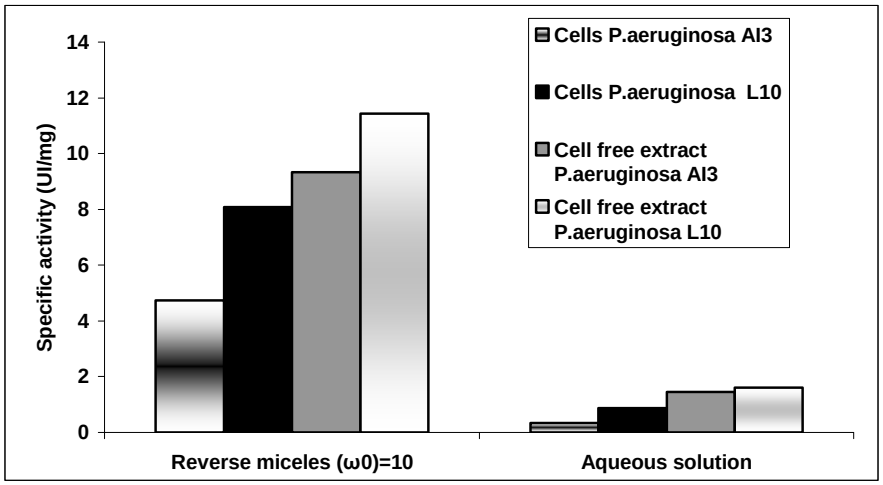

Figure 3- Acetohydroxamic acid synthesis in aqueous solution and at $w_0 = 10$ for both strains

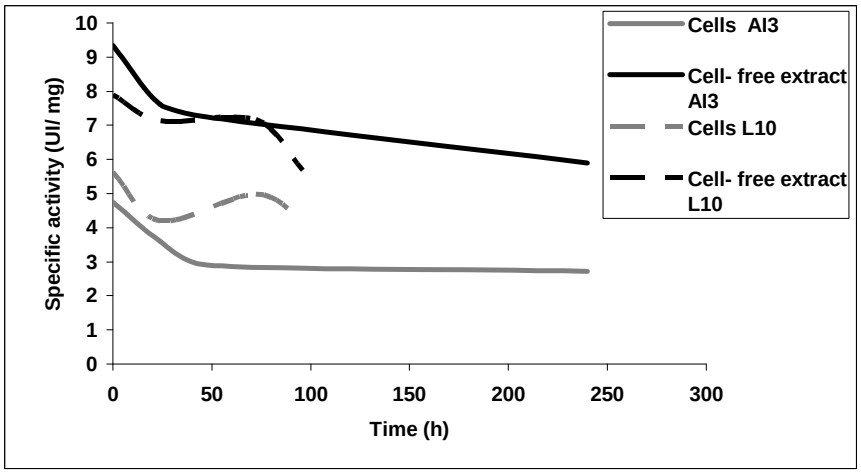

Figure 4-Study of stability for whole cells and cell free extract at 24ºC in reversed micelles

4-Conclusions

The reversed micellar system of TTAB in heptane/octanol seemed adequate to encapsulate whole cells and cell free extract with preservation and displaying an increase amidase activity of acetohydroxamic acids when compared with the conventional aqueous media. By choosing the appropriate water content w_0=10 transamidation reactions can be carried out in these systems with high performance. These changes in amidase activity can be explained by the diameter of the micelle possibly associated to a change in the enzyme secondary structure when entrapped

* Rita Pacheco. Tel +351-21-8317000 ext. 1229 . E-mail: rpacheco@deq.isel.ipl.pt

inside reversed micelles. Work is already in progress in order to understand such behaviour by Light Scatering and FTIR analysis.

Our preliminary studies of storage stability revealed a higher half-life for *Pseudomonas aeruginosa* AI3 than for *Pseudomonas aeruginosa* L10. The enzyme stability is very important parameter due to enzyme application as biocatalysts therefore the studies about this parameter will continue and also performance stability in reverse micelles and in aqueous solution in order to determine the optimal conditions of production of such important products such as hydroxamic acids.

Abstract

Ten fungal strains isolated of Mexican semi-desert were screened for ability to hydrolyze fucoidan in order to search microorganism capable to produce sulfated fucans-degrading enzymes. Plate assay and liquid fermentation experiments were carried out using *Laminaria japonica* fucoidan as only carbon source, testing three nitrogen sources. Growth was observed only in *Aspergillus niger* PSH, *Mucor sp*., and *Penicillum purpurogenum* GH2 in fucoidan-urea medium. The activity of fucoidanases was determined by reduced sugars. *Aspergillus niger* PSH showed the highest activity titles. This research indicate that filamentous fungi, using specific medium, are sources enable to induce active metabolism that act toward this class of polysaccharide.

1 Introduction

Fucoidan is a sulfated fucose hetero-polysaccharide, found in cell walls of brown algae with a wide variety of biological activities including anticoagulant, antithrombotic, antitumoral and antiviral being the most relevants against hepatitis, herpes and human immunodeficiency (AIDS) viruses (Berteau and Mulloy, 2003; Ellouali et al., 1993; McClure et al., 1992). Morever, preparations of polysaccharides with standard characteristics as well as medicines and supplements from these biopolymers also include enzymatic treatments. Although, scientific and practical interest of studying the relation between structure and biological activity has been studied, a detailed chemical structure of fucoidan elucidation remains unknown.

Specific (Glycosylhydrolases) enzymes capable to tailored fucoidan sulfated matrix are important tools for establish the structural characteristics and biological functions of this class of polysaccharide. Endo- and exo- fucoidanases have been principally found in marine bacteria as *Vibrio* sp. (Furucawa et al., 1992), *Pseudoalteromonas citrea* (Bakunina et al, 2002) *Pseudomonas sp.*, *Alteromonas sp.* (Sakai et al., 2004), *Flavobacteriaceae* sp., (Urvantseva et al., 2006), and marine invertebrates as *Haliotis* sp., *Mizuhopecten yessoensis* mollusks and *Strongylocentrotus nudus* sea urchin (Giordano et al., 2006).

There are any reports of terrestrial and neither fungal microorganism that hydrolyzes fucoidan. For that reason, the aim of the present work was to identify fungal strains that can growth over fucoidan medium as sources of active fucoidanases, and to evaluate enzymes excretion capacity over minimal conditions.

2 Materials and methods

Fucoidan of *Laminaria japonica* (molecular weight 100,000 Da) was obtained from Rizhao Jiejing Ocean Biotechnology Development Co.,Ltd.

The filamentous fungus studied in the present work were isolated from Northeast Mexican desert (Cruz-Hernandez et al., 2005), collected during scientific expeditions realized by the Fermentation Group of Food Research Department, Universidad Autonoma de Coahuila, (Saltillo, Mexico). Strains identification was carried out in the Micoteca of Universidade do Minho (MUM, Braga, Portugal). Five *Aspergillus*: *A. ustus* PSS, *A. niger* ESH, *A. niger* PSH, *A. niger* AA20, *A. niger* GH1; four Penicillium: *P. pinophilum* EH2, *P. pinophilum* EH3, *P. purpurogem* GH2, *P.* ESS; and one *Mucor sp.* were used.

The screening methodology was carried out preparing agar plates (60x15 mm petri dish) with fucoidan-peptone, fucoidan-urea and fucoidan-sodium nitrate medium. The concentration used were: carbon source 5 gL^{-1}, nitrogen source 2 gL^{-1} and agarose 10 gL^{-1} in 100 mM acetate buffer (pH 4.5). Each strain was tested by the tree different treatments; inoculation was realized in the center of the plate and incubation was at 30ºC for ten days (experiments were made by duplicate). The presence of growth were measured each 24 h.

Submerged fermentation was realized in 250 mL Erlenmeyer flask using a minimal medium of fucoidan and urea, 10 and 5 gL^{-1}, respectively. Culture medium was sterilized by microfiltration with membranes filter of 0.2 µm. Inoculum was prepared by transferring fungal spores to potato dextrose agar medium, incubated at 30 °C for 5 days. Spores were scraped into 0.01% Tween 80 solution and counted in a Neubauer chamber. The culture conditions used were: $1x10^6$ spores mL^{-1} of inoculum concentration, 30°C, 140 rpm, initial pH 5.0 and incubation time of 96h.

For biomass determination the mycelium obtained after filtration (membrane filter 0.45 µm, 47 mm) was dried at 150 W for 10 -20 min. Total sugar quantification was carried out using phenol-sulfuric acid method (Dubois et al., 1956). The protein concentration in fungal extracts was determined using Coomasie (Bradford) protein assay kit (Pierce).

Enzymatic activity was measured by the dinitrosalicylic acid technique (Miller, 1959) to estimate the release of reducing sugars using the following reaction: 900 µL of sustrate (fucoidan 10 gL^{-1} in 200 mM acetate buffer, pH 4.5) and 100 µL of enzyme extract incubated for 24 h at 37ºC. One unity (U) of enzyme was defined as the amount of enzyme able to releases 1 µmol of reducing sugars per minute. All data correspond to triplicates of independent experiments.

3 Results and discussion

Filamentous fungus have the ability to growth over complex substrates behind minimal conditions as well as their capacity to produce a wide range of commercially interesting metabolites. Due to their exceptional high capacity to express and secrete proteins, filamentous fungi have become indispensable for the production of enzymes.

Growth fungal evaluation over fucoidan was carried out with the purpose of found terrestrial microorganism able to depolimeryzate this complex polysaccharide. From the ten strains assesed, testing three diferent mediums, only *Aspergillus niger* PSH, Penicillum *purpurogenum* GH2 and *Mucor sp*., showed mycelium presence in fucoidan-urea plates (Fig. 1) after 24 h of inoculation. However, any strain growth in fucoidan-peptone and fucoidan-sodium nitrate complex. Mucor sp. and *A. niger* PSH colonies cover completely the agar plate after six days of incubation. On the contrary, peripheral growth zone of *P. purpurogenum* GH2 was only a small part of the agar.

The presence of fungal colonies can evidence that these microorganisms are capable to excrete metabolites able to hydrolyze the branched structure of fucoidan, consisting of 1,2-linked fucose residues with sulfate at C-4.

Aspergillus niger PSH | *Mucor sp* | *Penicillum purpurogem* GH2

Figure 1. Microorganism with growth presence over fucoidan-urea dishes

Submerged fermentation experiments were realized comparing the strains that showed growing capacity over fucoidan. Urea was selected as the nitrogenum source applied in the culture medium. The morphological form observed during the submerged culture where dispersed mycelial filaments. The particular form exhibited is determined not only by the genetic material of the fungal species but also by the nature of the inoculum as well as the chemical and physical culturing conditions (Papagianni, 2004).
Higher biomass production was 0.84 gL^{-1} with *Mucor sp.* and 0.49 gL^{-1} with *A.* PSH, after 72h (Figure 2a). As was observed in agar plates experiments *P*. GH2 biomass only reach values closed to 0.2 gL^{-1}. Substrate consumption was approximately 3.5 gL^{-1} of total sugars.

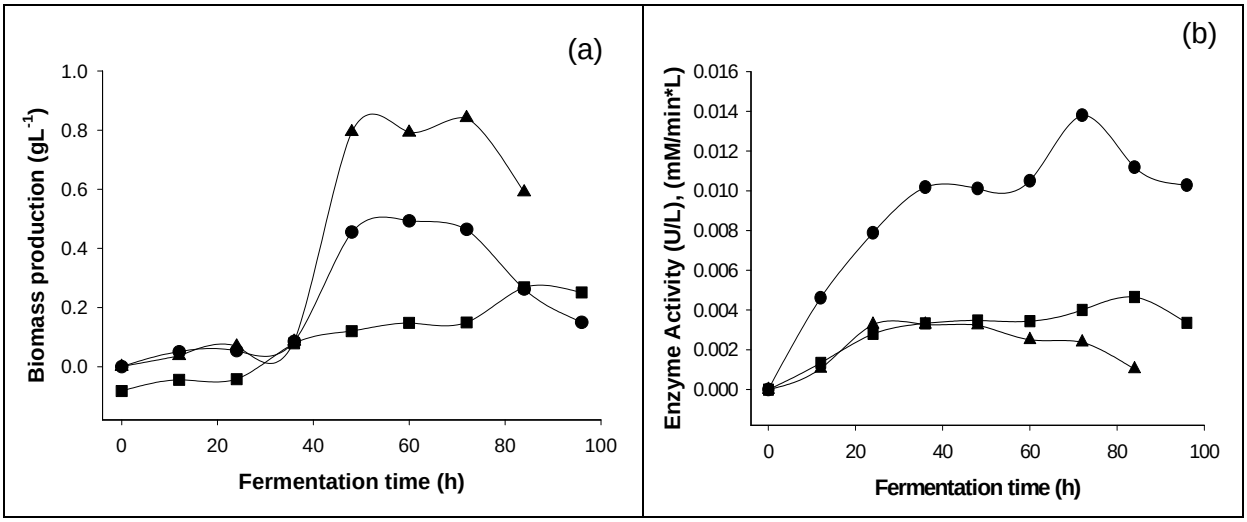

Figure 2. Submerged fermentation with fucoidan-urea medium of *Aspergillus niger* PSH (–●–), *Mucor sp*., (–▲–) and *Penicillium purpurogenum* GH2 (–■–): a) Biomass production; b) Enzyme activity.

Fucoidan activity (Fig. 2b) obtained by fungal strains was highest with *A.* PSH with values oscillating from 0.0102 to of 0.0138 UL^{-1} after 36h of fermentation. Mucor sp. and *P.* GH2 activities were 0.005 and 0.004 UL^{-1}. The enzymatic activity may be underestimated because active proteases were founded at the first 36 h of fermentation, principally in experiments with *P.* GH2.
Despite of enzyme activity were lower, there are any reports of fungal fucoidanases by induction procedure. Morever, fucoidan hydrolases reported by Alexeva et al*.,* (2002), Burtseva et al., (2000) and Bakunina et al., (2000) with marine bacteria and invertebrates exhibited weak catalysis.

The present study suggest that fungal strains from the genus *Aspergillus, Penicillium* and *Mucor* have the capacity for synthesize fucoidan hydrolytic enzymes, being potential microbiology tools for used in fermentation process, looking for the optimization in order to obtain higher titles under different processes.

Topic: Integration of life sciences & engineering.

Abstract

The aim of this research was the optimization of poly(3-hydroxybutyrate) – P(3HB) – production obtained in submerged cultures of *Bacillus megaterium* in a mineral medium, using sucrose as carbon source and the nitrogen as the limiting substrate. A bench-scale bioreactor was used in order to obtain experimental data for phenomenological modeling of the biopolymer production, microbial growth, and substrate consumption. From an experimental design, which was carried out in shaker at 30°C and 160 rpm, it was evaluated the best initial sucrose concentration and carbon-to-nitrogen ratio in order to maximize the biomass accumulation and biopolymer production. It was observed the P(3HB) accumulation in bacteria without the need of nitrogen limitation and a strong correlation between accumulated P(3HB) and pH. Bench-scale bioreactor experiments were carried out and showed the importance of a control pH strategy. The proposed model was implemented in the EMSO process simulator and its parameters were estimated using this tool and the experimental data from the bioreactor. The simulation results showed good agreement with the experimental data.

1 Introduction

Plastics have been regarded as ideal materials for the production of various consumer products because of their durability and inherent resistance to degradation. However, these same qualities are sources of environmental and waste management problems. These problems have created much interest in the development of biopolymer. In addition, biopolymers can be obtained from agriculture or from biotechnological processes and are therefore, in principle, available from renewable resources (Luengo et al., 2003; Reddy et al., 2003).

Polyhydroxyalkanoates (PHAs) biopolymers are polyesters synthesized by numerous bacteria and are accumulated on inclusion bodies in the cytoplasm of the cells as energy storage. They are produced from renewable carbon sources and, generally, with limiting nutrient; and their main characteristic is the biodegradability (Lee, 1996b; Madison and Huisman, 1999). Poly(3-hydroxybutyrate) (P(3HB)) is the most characterized PHA, partially crystalline polymer, and with material properties similar to polypropylene (Lee, 1996a; Sudesh et al., 2000).

The aim of this research was the optimization of poly(3-hydroxybutyrate) – P(3HB) – production obtained in submerged cultures of *Bacillus megaterium* in a mineral medium, using sucrose as carbon source and the nitrogen as the limiting substrate.

2 Materials and methods

2.1 Microorganism and culture medium: The bacterium used in this study was *Bacillus megaterium*, DSM 32^T. The mineral medium is the same used in Wang and Lee (1997).

2.2 Design of experiments: Shaker experiments were carried out, according to a central composite design with three repetitions in the central point, in order to evaluate the best initial sucrose concentration (S) and carbon-to-nitrogen ratio (C:N) for increasing cell concentration and accumulated polymer. In Table 1, it was shown the concentration of sucrose and source of nitrogen (SN) to give the desired carbon-to-nitrogen ratio. Batch fermentations were carried out in 250 mL Erlenmeyer flasks containing 50 mL of culture medium with initial pH = 7. The flasks were inoculated and maintained at 30°C and 160 rpm for the requested time. Samples were collected in 4, 8, 12, 16, 20 and 24 hours.

Table 1: Design of experiments

EXP	X1 (S)	X2 (C:N)	S (g·L^{-1})	C:N	SN (g·L^{-1})
1	1	1	44	22	2.00
2	1	-1	44	8	5.50
3	-1	1	16	22	0.73
4	-1	-1	16	8	2.00
5	0	$-\sqrt{2}$	30	5	6.00
6	0	$\sqrt{2}$	30	25	1.20
7	$-\sqrt{2}$	0	10	15	0.67
8	$\sqrt{2}$	0	50	15	3.33
9a	0	0	30	15	2.00
9b	0	0	30	15	2.00
9c	0	0	30	15	2.00

2.3 Bench-scale bioreactor: For larger scale production, a 5 L bioreactor was used containing 4 L of the culture medium. The initial substrate concentration (16 g·L^{-1} of sucrose and 2 g·L^{-1} of ammonium sulphate) was chosen according to the optimal point of the surface response curve from the design of experiments.

Bench-scale bioreactor experiments were carried out with dissolved oxygen and pH control. Cultivations parameters were as follows: pH, 7; temperature, 30°C; aeration, 4 L/min; stirred speed, 200-700 rpm. The dissolved oxygen (pO_2) was controlled changing the stirred speed in order to keep the value of dissolved oxygen above 40%. Bench-scale bioreactor experiments without pH control, but keeping the other conditions unchanged, were also carried out.

2.4 Analytical procedures: Total biomass was evaluated by dry weight, from 40-10 mL of culture broth. The cell suspension was centrifuged at 3500 rpm for 20 min at 4°C, washed with distilled water, transferred to pre-weighed vials and dried in an oven at 80°C till constant weight. P(3HB) amount was determined by propanolysis of monomers according to the method of Riis and Mai (1988). Residual biomass was calculated total biomass less biopolymer amount, once biopolymer was accumulated into the cell. The sucrose was analyzed according to Dubois et al. (1956) and by HPLC using a Rezex-RHM (300 mm x 7.8 mm) column at 80°C and RI detector. Nitrogen was determined by the phenol-hypochlorite reaction according to Weatherburn (1967).

2.5 Modeling: Different mathematical models for microbial growth, biopolymer production and substrate consumption were analyzed (Khanna and Srivastava, 2005; Raje and Srivastava, 1998). A new model which is a improved version of the Khanna-Srivastava model presenting a lower number of parameters. This model is shown in Table 2. All models were implemented in the EMSO process simulator (Soares and Secchi, 2003) and their parameters were estimated using this tool and the experimental data from the bioreactor.

Table 2: Equation of the modified model

Residual Biomass(X_R):	$\frac{dX_R}{dt} = (\mu - k_d) \cdot X_R$
Specific grow rate (μ):	$\mu = \mu_m \left(\frac{S}{K_{SS} + S} \right) \cdot \left(\frac{N}{K_{NS} + N} \right)$
Biopolymer (P):	$\frac{dP}{dt} = (k_1 \cdot \mu + k_2) \cdot X_R$
Sucrose(S):	$\frac{dS}{dt} = -(\alpha \cdot \mu + \gamma) \cdot X_R$
Nitrogen (N):	$\frac{dN}{dt} = -\frac{\mu}{Y_{RN}} \cdot X_R$

3. Results and discussion

3.1 *Design experiments*

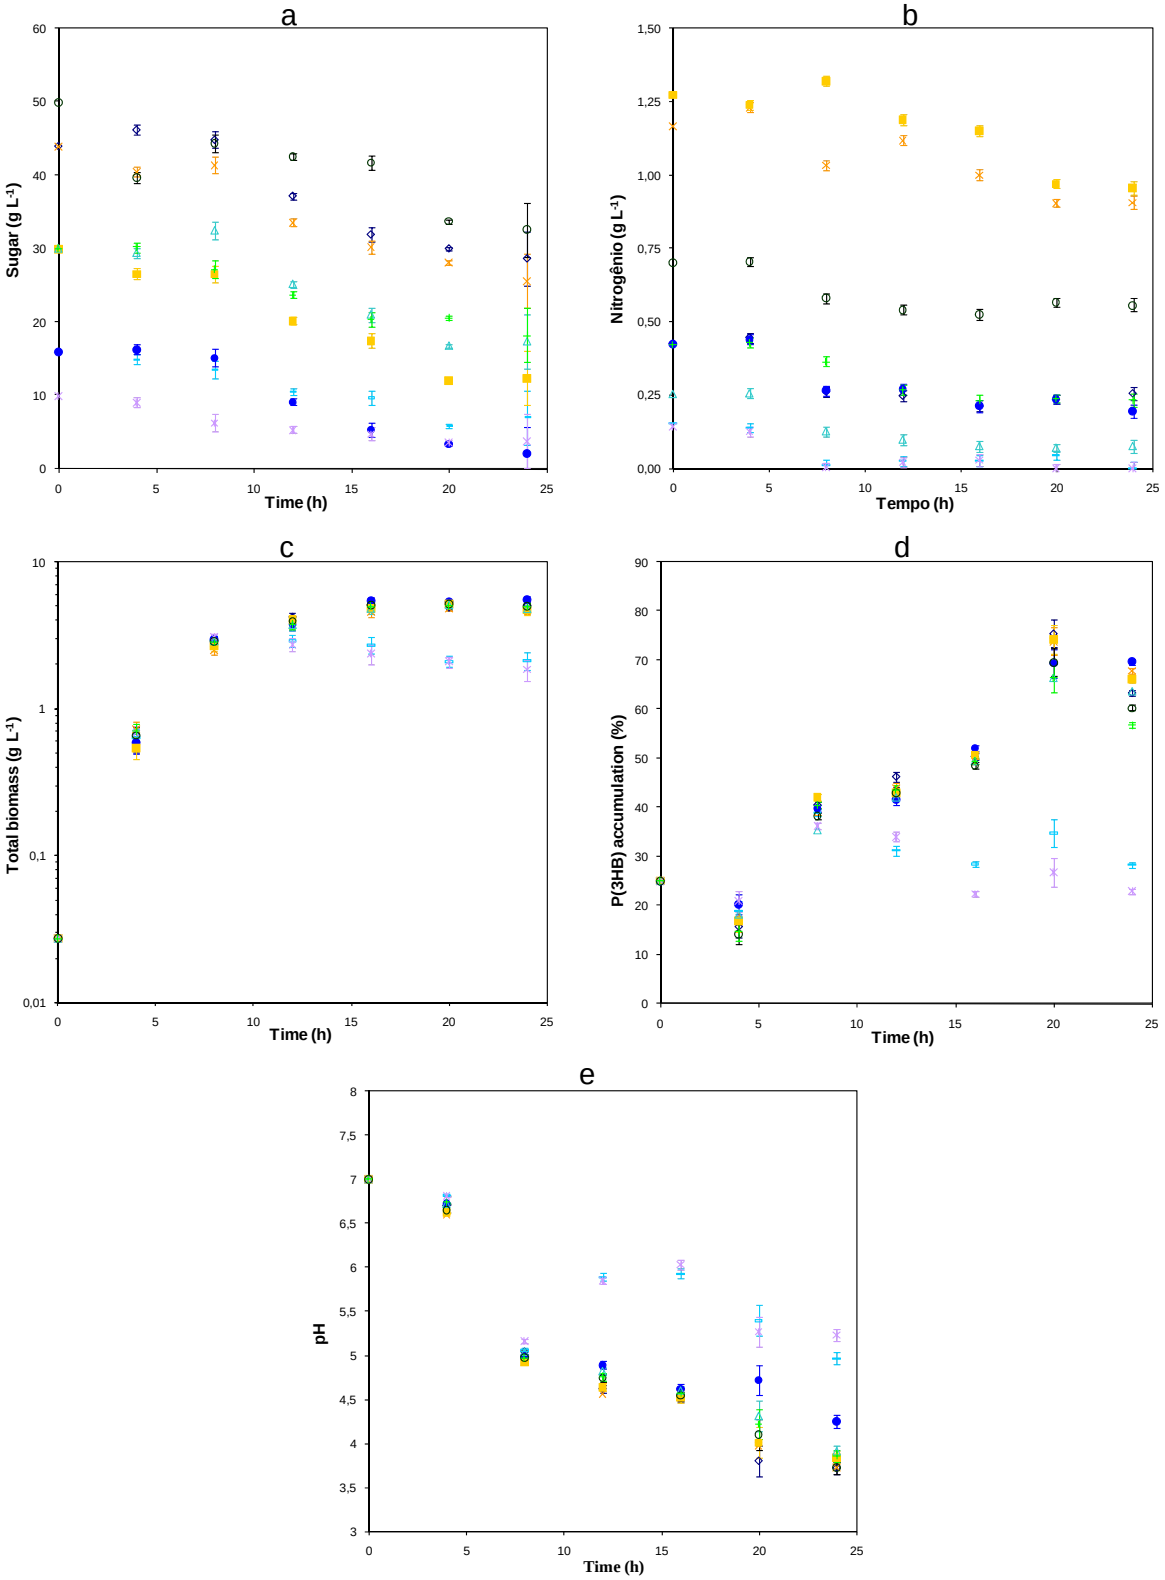

Figure 1: Time evolution of sugar concentration (a), nitrogen concentration (b), total biomass concentration (c), polymer accumulation (d) and pH (e) throughout the culture.

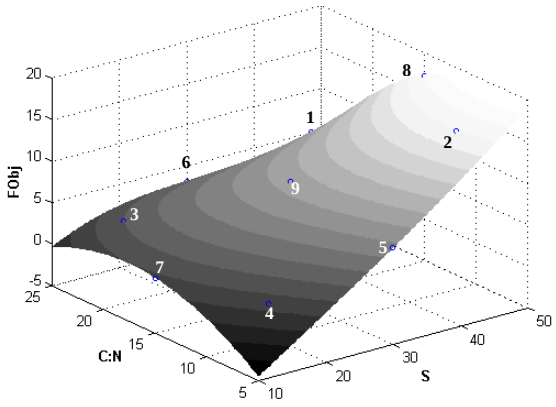
In the experiments, P(3HB) was accumulated in the cell about 75% at 20 hours of culture. In most of the cases, there was no limitation in the sucrose or nitrogen (Figure 1a and 1b) but a decreasing in P(3HB) accumulation after 20 h could be seen (Figure 1c) and no more increasing in the biomass could be detected (Figure 1d). The pH decreased with the time (Figure 1e) and it was observed a strong correlation between accumulated P(3HB) and pH of the medium.

It is observed that *B. megaterium* shows different behavior from bacteria commonly used on biopolymer production, like *R. eutropha*, since it is able to produce large amounts of P(3HB) without nitrogen limitation. Similar results are found in Omar et al. (2001) and Maccol et al. (1996).

The results of the design of experiments were analyzed using surface response for biomass, polymer accumulated, and residual sucrose. With the fitted equations from this surfaces it was constructed an objective function to determine the best condition to maximize the biomass accumulation and biopolymer production and also to minimize the residual sucrose.

This objective function is shown in equation (1) and also in Figure 2 with weight w = 0.2. The optimal point was found to be close to the experiment number 4 (S = 16 g·L^{-1} e C:N = 8), which was then chosen to carry out the experiments in bench-scale bioreactor.



$$F_{Obj}(S,C:N) = (1-w)\cdot S_R(S,C:N) - w\cdot\left(\frac{P(S,C:N)\cdot X_T(S,C:N)}{100}\right) \quad (1)$$

Figure 2: Plot of the objective function and the equation that represents this function.

3.2 *Bench-scale bioreactor*

The experiments without pH control (SCPH) and with pH control (CCPH) were done in duplicate in the bench-scale bioreactor. The results (medium values of duplicates) are shown in Figure 3. The SCPH experiment was finished earlier than the CCPH, after 12 h, because the dissolved oxygen came back to 100% (Figure 3e).

Comparing the results from bench-scale bioreactor with those from shaker we could observe that the polymer accumulation is much lower in the bioreactor, even without pH control, which is the condition corresponding to the shaker process. This decrease in the P(3HB) accumulation compared with shaker was also observed in Omar et al. (2001).

In Figure 3a, it can be observed that total biomass (Xt) and residual biomass (Xr) were lower in SCPH than in CCPH experiments, although the P(3HB) amount was similar. Therefore, P(3HB) accumulation (%) into the cell in SCPH experiments was higher than the CCPH (Figure 3b). As in SCPH experiments there was no limitation either in sucrose or in nitrogen, the cells growing interruption could be attributed to the final pH was very low. These results show that: i) the use of a pH based control strategy is very important and ii) maintaining pH = 7 during the whole process, as in CCPH experiments, is not the most adequate control strategy.

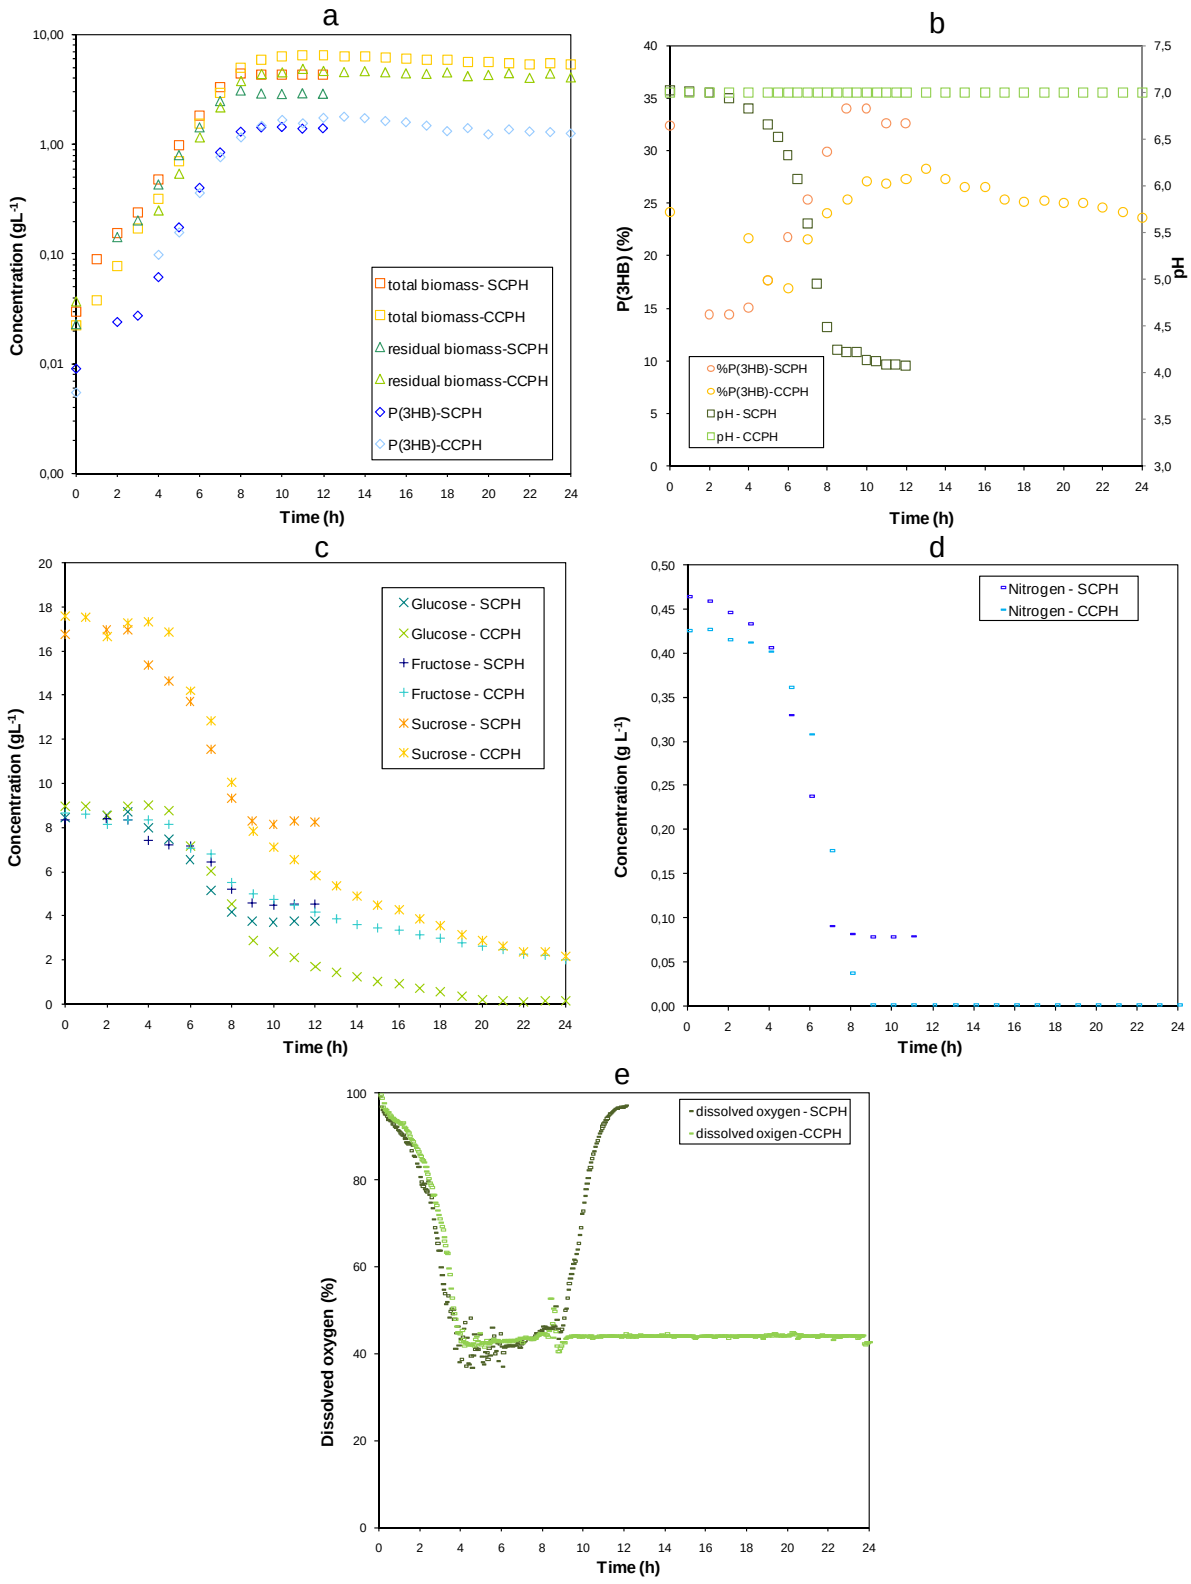


Figure 3: Time evolution of total biomass concentration, biopolymer accumulation and residual biomass (a), biopolymer accumulated and pH (b) sugar concentration (c), nitrogen concentration (d) and dissolved oxygen (e) throughout the culture without control pH (SCPH) and pH controlled (CCPH).

The values of parameters estimated using experimental data from the bioreactor with pH control are shown In Table 3. The simulation results showed good agreement with the experimental data, as pointed by the low value of the objective function.

Table 3: Parameter values for CCPH experiment.

Parameter	Unit	Values
α		2,0606
γ	1/h	0,0849
k_1		0,4053
k_2	1/h	-0,0079
k_d	1/h	0,0073
K_{SS}	g/L	0,1928
K_{SN}	g/L	0,0447
μ_m	1/h	0,7979
Y_{RN}		10,6314
Objective function		**0,1575**

5. Conclusions

Results of shaker experiments shown that *Bacillus megaterium* is able to produce large amounts of P(3HB) without nitrogen limitation. Results of shaker and bench-scale experiments realized the importance of a programmed pH control strategy, different from the used in CCPH experiment.

Therefore, more experiments need to be done in order to test new strategies for pH control in specific ranges (like as from 5 to 7), that can be able to generate similar results of P(3HB) accumulated in cells as the ones obtained in the shaker experiments.

Topic: Integration of life sciences & engineering.

Abstract

Oxygen supply is known to be an important constraint on the growth of the aerobic sporeforming bacteria (Liu et al. 1994). However, the effects of oxygen on sporulation of these bacteria have been limited studied. In *Bacillus thuringiensis* (Bt), sporulation is associated with production of an entomocidal parasporal crystalline toxin, also known as δ-endotoxin, which is generally the most important feature of this bacterium (Aronson, 1993; Sarrafzadeh et al. 2005). Thus the effect of oxygen in relation to toxicity must be considered too. The actual disagreements between reports show that oxygen role is far from to being completely understood (Avignone-Rossa and Mignone. 1995). Statistical analysis could be a very powerful tool to interpret the diverse results at this situation (Montgomery et al. 2001). In this work, attempts are made to study the effect of dissolved oxygen (DO) on sporulation development of Bt. investigations have been carried out involving fed-batch cultivation of *Bacillus thuringiensis* H14 followed by a batch culture after 24 h at different DO concentration. The sporulation in three different levels of DO (0, 50 and 100%) was followed by using microscopic methods and on-line measurements. The viability decreasing due to sporulation was also monitored. Statistical analysis of the effect of oxygen in sporulation was performed using a regression method and with the help of Minitab as the available software. The results showed a significant effect ($P < 0.05$) of oxygen not only on total spore formation but also on mature spore liberation. The statistical models were proposed to show the relations between sporulation development and oxygen levels. These statistical models were able to predict satisfactory the sporangium and mature spore formation at different levels of DO.

1) Introduction

The potential of *Bacillus thuringiensis* for use as a control agent of insects has provided a promising natural insecticide which can be an alternative to the chemical insecticides or as a part of integrated pest management system (Rowe & Margaritis 1987; Feitelson et al. 1992). *Bacillus thuringiensis* is a large gram-positive and spore-forming bacterium that produces, concomitantly with sporulation, an entomocidal parasporal crystalline protein, also known as δ-endotoxin (Aronson 1993, 2002; Agaisse & Lereclus 1995). *B.*

* Corresponding author. Tel + 982161112185. E-mail: sarrafzdh@ut.ac.ir

thuringiensis serotype H14 is the most effective microbial control agent available to date, against the larvae of dipterans such as mosquitoes and blackflies (de Barjac 1978). Large quantities of spores with high insecticidal activity are required for practical applications. Therefore, an engineering approach is needed to ensure a suitable environment for growth and δ-endotoxin synthesis. Oxygen is necessary for all aerobic fermentation. Maintaining the appropriate concentration of dissolved oxygen has been pointed out as an important factor in the fermentation of *B. thuringiensis* (Avignone-Rossa & Mignone 1995; Morris et al. 1996; Flores et al. 1997) Although there is a considerable amount of literature available in relation to the effects of oxygen on the biomass concentration (Liu et al. 1994) and toxin synthesis (Foda et al. 1985). The research was invariably carried out under constant aeration conditions, all along the culture, in flasks or laboratory fermenters. However the oxygen demands of culture are not the same all along the culture and depend strictly on the dominant physiological state of the microbial population in the culture. For this reason, there is no a general agreement between all authors and the reports are very diverse. Statistical analysis is a good tool in this situation to make clear the real requested conditions for aeration. Statistical analysis is used not only to optimize fermentation conditions but also it could be used to describe and predict the culture behavior (Montgomery et al. 2001). The aim of our work was to study the production of the spore of Bacillus *thuringiensis* H14 and statistical analysis of it. We decided to use regression analysis to determine the correlations between the total spore, mature spore and sporangium with dissolve oxygen percent during the time.

2) Materials and methods

Microorganism and media

Bacillus thuringiensis H14 (Ecautec, Tahiti) was used. A preculture flask containing 500 ml of medium was incubated at 30 °C on an orbital shaker for 9 h and used to inoculate the fermentor. The composition of the culture medium was (g/l): glucose, 5; hydrolysed casein, 4.5; yeast extract, 0.5; ammonium sulphate, 6; K_2HPO_4, 1.4; KH_2PO_4, 1.4; $MgSO_4$. 7 H_2O, 0.61; $CaCl_2$, 0.332; $MnSO_4$. 7 H_2O, 0.006. A concentrated medium, containing (g/l): glucose, 240; hydrolysed casein, 155; yeast extract, 25, was added during fed-batch phase. The pH of the medium was adjusted to 6.8 by 3 M NaOH (Sarrafzadeh et al. 2005).

Fermentation procedure

The fermenter (Biolafitte) had a maximum working volume of 15 l in which 9 l of culture medium were sterilized in situ. three fermentations were initiated under identical conditions in batch mode at 30 °C. Fed-batch cultures were started from 4 to 24 h of fermentation at a constant feed rate of 150 ml/h. Dissolved oxygen (DO) was monitored continuously and maintained above 20% of saturation during the growth period. During the sporulation phase a different oxygenation level was maintained. The three oxygen concentration performed were 0%, 50% and 100% which we define as interrupted, non-limited and saturated, respectively. The latter was carried out using pure oxygen which replaced air after 24 h of culture. The pH was maintained at 6.8 during the growth phase by 3 M NaOH but its increase during the sporulation phase was not controlled.

Sporulation, cell lysis and crystal formation

Sporulation, formation of inclusion bodies and cell lysis were monitored using a phase contrast microscope (Olympus Bx60). Cell counts (vegetative and sporulated cells) were

carried out using this microscope and a Thoma chamber. Unlysed sporulated cells were counted as spores. Sporulation was determined as the ratio of lysed and unlysed sporulated cells, which were distinguished due to their refractile nature, over the total cell count. The percentage of sporulated lysed cells vs. the total cell count has also been calculated as a mature spore count (Sarrafzadeh et al. 2005).

Statistical treatment

Regression analysis of the data obtained and three statistical models explaining the effects of the studied parameters establishing the optimal conditions of the parameters studied for total spore, mature spore and sporangium production were carried out using Minitab package for personal computers.

3) Results and discussion

A set of fermentation experiments, for determining the values for total spore, mature spore and sporangium at the different levels of dissolve oxygen (0%, 50% and 100%) were carried out. The data obtained were statistically analyzed. First, a second order model with all terms included was tested. The analysis of variance indicated that the model should be reduced in order to obtain better significance of the individual parameters. The reduced models obtained were as follows:

$$S_1 = -28.328+2.641t+0.952\times O-0.0034O^2-0.0237tO \quad (1)$$

$$S_2 = -102.488+4.281t+0.895\times O-0.032tO \quad (2)$$

$$S_3 = 74.435-1.637t+0.0098O-0.0029O^2+0.0080tO \quad (3)$$

Where S_1 refers to total spore percent; S_2 refers to mature spore percent; S_3 refers to sporangium; O refers to the oxygen percent of saturation; and t refers to time (h). These statistical models were able to predict satisfactory the total spore, mature spore and sporangium formation at different levels of dissolved oxygen during the time.

All the terms included in the presented statistical model were found to be significant at 95% level of significance, and the models were found to explain 88.9%, 94.2% and 89.3% of the experimental data, respectively.

Statistical analysis showed that the dissolve oxygen and time has the significant effect ($P<0.05$) on the total spore and mature spore. The dissolve oxygen has insignificant effect ($P>0.05$) on the sporangium but oxygen is not omitted of third model because square of oxygen and interaction of oxygen and time have the significant effect on the sporangium.

Figure 1, Figure 2 and Figure 3 provide two-dimensional views where all points that have the same total spore, mature spore and sporangium, respectively, are connected to produce contour lines of constant responses. Figure 1 and Figure 2 show that with decrease of oxygen at the constant time total spore and mature spore percent increase. Figure 3 show that sporangium production is independent of oxygen percent.

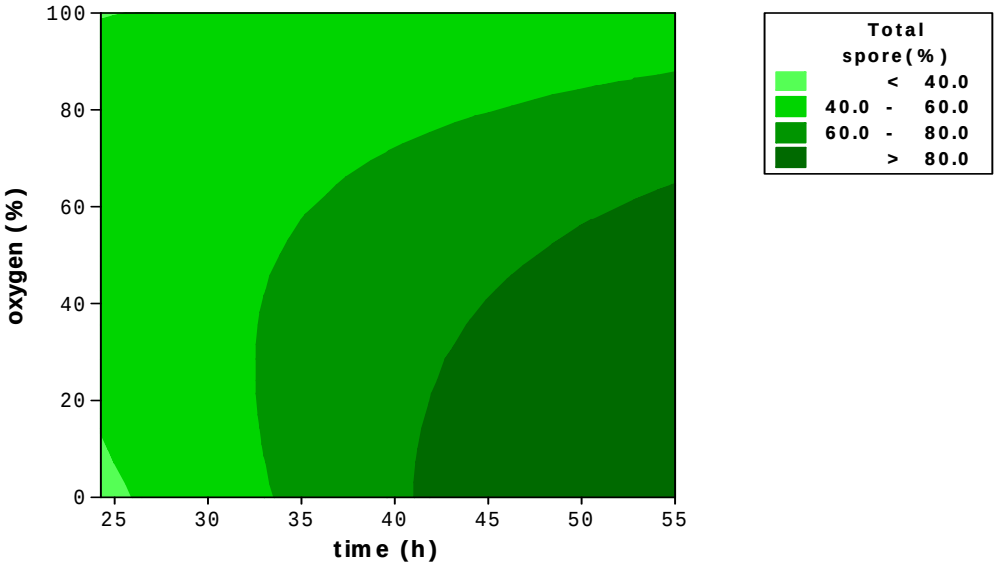

Figure 1. Contour plot for total spore production by *Bacillus thuringiensis* H14 at different levels of oxygen (% of saturation) and time.

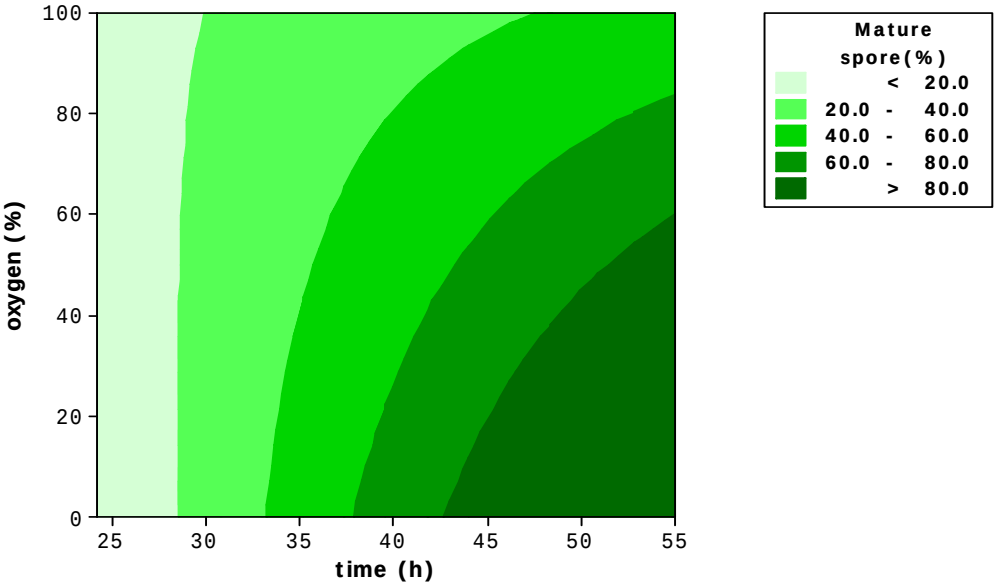

Figure 2. Contour plot for mature spore production by *Bacillus thuringiensis* H14 at different levels of oxygen (% of saturation) and time.

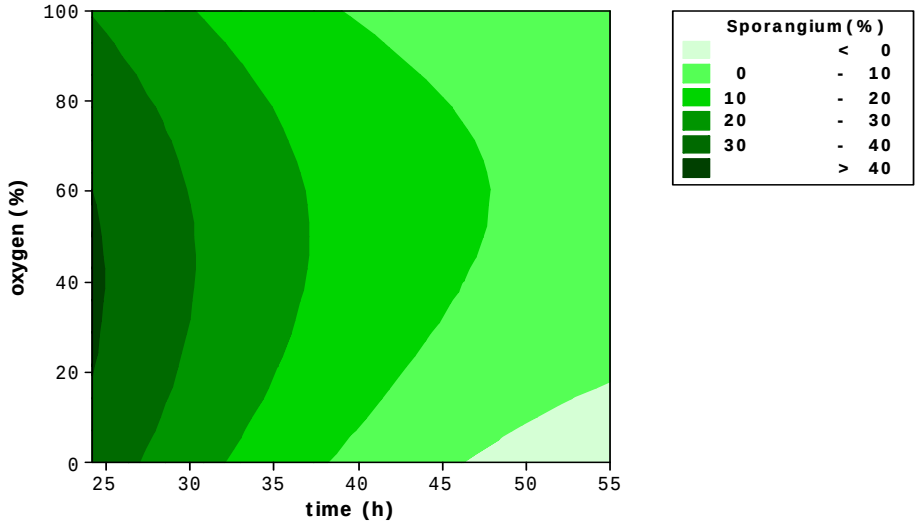

Figure 3. Contour plot for sporangium production by *Bacillus thuringiensis* H14 at different levels of oxygen (% of saturation) and time.

Abstract

The characterization of Olive Mill Wastewaters (OMW), focusing the phenolic compounds, is one of the aims of the present work. As a first approach to characterize the phenolic compounds of OMW, the extraction methods used were: a liquid-liquid extraction by acidified ethyl acetate and a solid-liquid extraction with acidified methanol. The analysis of these extracts by reversed phase liquid chromatography confirmed that hydroxytyrosol was the most abundant phenolic compound in OMW, and that this compound was more efficiently recovered by the solid-liquid extraction technique. It was also a goal of this work to study the phenolic compounds toxicity to some yeast strains. Among the phenolic compounds tested catechol is the most inhibitory one to the cells. The phenols degradation was quite difficult, particularly when more easily degradable carbon source is still present in the medium.

1 Introduction

The olive oil consumed in the world is mainly produced in the Mediterranean area. The three -phase extraction system is the most common technology used in these countries, with exception of Spain, the most important producer, that mostly uses the two-phases process. These technologies differ in the water requirements. The three-phase extraction process requires large amounts of water, resulting in a large amount of effluent, known as Olive Mill Wastewater (OMW). OMW represents a major environmental problem due to its high organic content.

OMW is often characterized by a strong acidic smell and an intensive brown to dark color due to the presence of biodegradable and recalcitrant compounds (such as polyphenolic compounds). The phytotoxicity of the olive mill wastewaters can be attributed to the phenolic compounds (Lanciotti et al, 2005). In fact, the olive pulp is very rich in phenolic compounds (Cardoso et al, 2005), but only 2% of the total phenolic content of the olive fruit passes in the oil phase, while the remaining amount is lost in the OMW (approximately 53%) and in the pomace (approximately 45%) (Rodis et al., 2002).
Due to their instability, OMW phenols tend to polymerize during storage into condensed high-molecular-weight polymers that are difficult to degrade (Crognale et al, 2006). Thus, uncontrolled OMW disposal can create severe risks to water and soil quality. OMW is currently concentrated by evaporation in open pools, but this method is not satisfactory because it only reduces the volume of waste without treating the pollutants and a black foul-smelling sludge, difficult to remove, is produced. The research on OMW valorization is focused on the recovery or on the degradation of the phenolic compounds since its presence

* Corresponding author. Tel + 351-253604413. E-mail:ibelo@deb.uminho.pt

is considered to be the limiting step in the biotreatment of OMW (Tsioulpas et al, 2002).

Instead of disposal solutions an approach of using this waste as a resource to be valorized is of greater interest. OMW contains sugars, lipids, mineral elements and phenolic compounds (10 % of the organic matter) that could be either directly recovered by chemical extraction and subsequent purification, or utilized as a basis for fermentative processes. Thus, the extraction and purification of biologically active compounds (namely biophenols) turns OMW into a source of natural antioxidants. These compounds are object of growing interest in pharmaceutical and food industries since reactive oxygen species are involved in the onset of several human diseases and in the oxidative degradation of food (De Marco et al, 2007).

One of the aims of the present investigation was the characterization of different OMW, from north of Portugal, focusing the phenolic compounds identification. Subsequently to this identification it was also a goal of this work to study its toxicity to yeast strains that are under investigation for potential use of OMW as culture media.

2. Materials and Methods

Characterization of phenolic compounds in OMW

Extraction of phenolic compounds

The olive oil mill wastewater was collected in a continuous three phases olive oil factory in the north of Portugal and stored at -80 ºC right after arrival to the lab. The phenolic compounds were extracted from the OWM by two distinct extraction methods: (1) a liquid-liquid extraction by acidified ethyl acetate, according to the procedure of De Marco et al. (2007) and (2) a solid-liquid extraction with acidified methanol. For the solid-liquid procedure, an OWM sample was lyophilized and 2 g of the resulting freeze-dried material was defatted 3 times with 20 mL of *n*-hexane, and the residue was extracted 5 times with 20 mL of methanol at pH 2. The methanolic extracts were filtered, combined, concentrated under vacuum and the dry residue was dissolved in 10 mL of methanol.

Colorimetric and HPLC analysis of the phenolic extracts

The total concentration of phenolic compounds in the phenolic extracts was determined by an adaptation of the Folin-Ciocalteu method (Singleton and Rossi, 1965), using tyrosol as a reference.

HPLC analysis was performed on a HPLC apparatus from Knauer equipped with a Smartline 1000 bomb, an automatic Smartline Manager 5000 degassing unit, a Smartline 2500 UV/Vis detector and a JASCO automatic sampler, model AS-2057. The column (Nucleosil 100-5 C18 Macherey-Nagel, 250×4.6 mm) was kept at 30ºC using a Gecko 2000 oven. The results were recorded and processed using a Knauer Claritychrom software, version 2.4.4.80. The mobile phase was (A) formic acid 0.1% and (B) acetonitrile containing 0.1% formic acid. The solvent gradient started with 97% A and 3% B reaching 91% A at 4 min, 85% A at 15 min, 84% A at 25 min, 60% A at 70 min, 10% A at 80 min followed by an isocratic plateau for 5 min and return to initial conditions. Hydroxytyrosol in the phenolic extracts was identified and quantified by the comparison of the retention time of the peak and the correlation of its area to the retention time and to the calibration curve of the standard, respectively.

Phenolic compounds toxicity to lipolytic yeast strains

Two OMW's samples (A and B) with the composition shown in Table 1 where used. Chemical Oxygen Demand (COD), Solids (total, volatile and dissolved), Nitrogen (Kjeldahl) were determined according to Standard Methods (APHA et al., 1989). Reducing sugars were measured by DNS method. Samples collected through fermentations were analyzed for COD, sugars, total phenols and by the methods above described.

Table 1. Characterization of OMW's used

Parameter [a]	Olive Mill Wastewater	
	A	B
pH	4.71	4.93
COD/(g·L^{-1})	99 ± 1	191 ± 2
Total Solids/(g·L^{-1})	148± 3	119.6 ± 0.2

Total protein/(g·L^{-1})	1.2 ± 0.2	1.3 ± 0.0

[a] Data are mean values ± standard deviation (n=20)

Phenolic compounds toxicity and biodegradability

The phenolic compounds degradation and toxicity tests were carried out in microplates for 4 days and 6 yeast strains were used: *C. rugosa* PYCC 3238, *C. cylindracea* CBS 7869, *C. rugosa* CBS 2275, *Y. lipolytica* CBS 2073, *Y. lipolytica* W29 ATCC 20460 and *Y. lipolytica* IMUFR. Cells were pre-grown in YPD medium, for 24 h. After that, 20 µL of cells suspension were transferred to each microplate well with the sterilized phenolic medium. The phenolic mediums were composed of YPD medium (10 fold diluted) with different phenolic compounds (commonly found in OMW), such as tyrosol, hydroxytyrosol, cafeic acid, cathecol, oleuropein, syringic acid and vanillic acid.

In order to evaluate the induction of phenolic metabolism in yeast strains, assays with pre-adaptation to phenolic compounds were carried out. Cells were pre-grown in YPD medium by 24 h, harvested (12225 g, 5 min), re-suspended in the phenolic medium (YP and phenolic solution in phosphate buffer pH 7.2, 0.1 M) and grown for 24 h in this conditions. After this pre-adaptation phase, cells were transfered to OMW mediums (A and B). Batch cultures were carried out in 500 mL Erlenmeyer baffled flasks filled with 200 mL of OMW sterilized medium, supplemented with ammonium chloride at a concentration corresponding to 10% (w/w) of the COD value and yeast extract (40% of the NH_4CL added).

Respiratory activity assays were carried on a Biological Oxygen Monitor System (YSI 5300A) with a stirred thermostatic bath. *Y. lipolytica* W29 culture with, approximately, 22 h of growth was harvested, washed and ressuspended in sodium phosphate buffer in order to obtain a final suspension with an optical density of 0.3 (λ = 600 nm). This suspension was aerated for 30 min to ensure the oxygen saturation and after this time was placed in the temperature-controlled vessel at 27 ºC. The vessels were closed and the decrease in air saturation percentage was monitored over time. The linear decrease observed between time zero and carbon source addition corresponds to the endogenous respiration rate. To determine the oxygen uptake rate due to substrate oxidation, different volumes of a glucose solution (10 g·L^{-1}), phenolic solution (tyrosol, oleuropein, syringic acid and gallic acid 2.5 g·L^{-1} each and hydroxytyrosol 1.25 g·L^{-1}) or OMW (COD 115 g·L^{-1}) were injected into the vessel. The slope of the linear decrease in the air saturation percentage immediately after carbon source injection corresponds to the total respiration rate. In order to calculate the influence of exposition of the yeast suspension to catechol solution, the cell suspension was incubated with a catechol solution (0.3 g·L^{-1}) for 30 min with aeration. After the required contact time, the cell suspension was placed in the vessels in order to assess the metabolic state of the yeast culture by respiratory activity as described above.

3. Results and discussion

Characterization of phenolic compounds in OMW

The total amount of phenolic compounds recovered from the OMW by the solid-liquid extraction procedure was approximately three times higher than that obtained by the liquid-liquid extraction methodology (5.1 mg/mL and 1.7 mg/mL, respectively). For the two extracts, the main phenolic chromatographic peak was eluted at 8.9 min (Figure 1), and this corresponded to hydroxytyrosol. The recovery of this compound accounted for 0.81 mg/mL and 0.06 mg/mL of OMW, for the solid-liquid and the liquid-liquid extraction procedures, respectively.

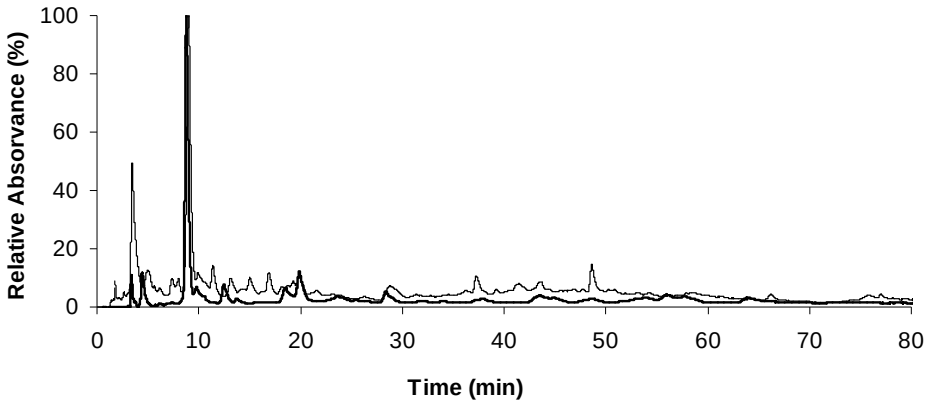

Figure 1. Chromatographic profiles of phenolic extracts of OMW at 280 nm obtained by liquid-liquid extraction (▬) and solid-liquid extraction (▬) procedures.

Phenolic compounds toxicity and biodegradability

The effect of different phenolic compounds on each yeast strain growth was evaluated by the assays in microplate. Typical batch growth curves profile for the experiments with *Y. lipolytica* W29 and C. *rugosa* CBS strains are shown in Figure 2.

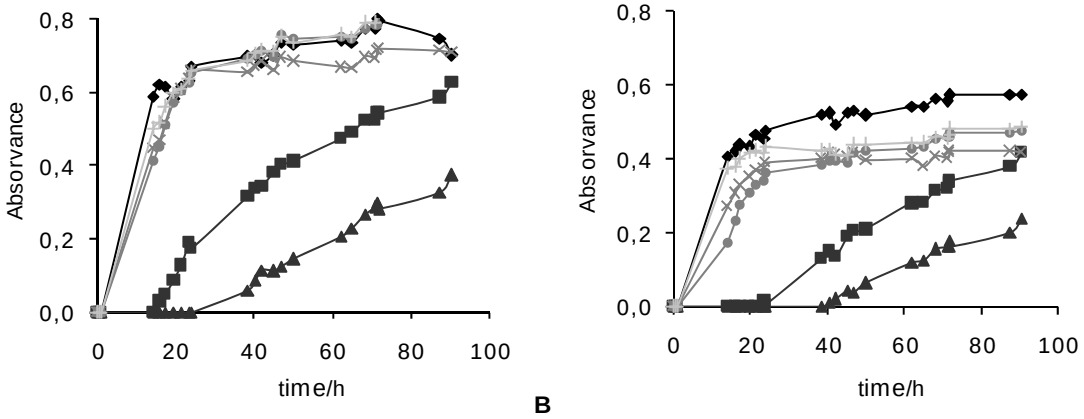

Figure 2. Batch growth profile of *Yarrowia lipolytica* W29 (A) and *Candida rugosa* CBS (B) in YPD medium (♦) and phenolic mediums: Catechol (▲), Hydroxityrosol (●), Caffeic Acid (■), Tyrosol (×) and Oleuropein (+).

For the phenolic concentrations used (1 $g \cdot L^{-1}$), it was observed that the final biomass concentration decrease in phenolic mediums comparatively to YPD medium for all strains used, except for *Yarrowia lipolytica*. Beside this difference, it was verified that the cells still grown in the presence of phenolics. However, in the presence of catechol the cell growth (for all strains) decreased substantially. An adaptation phase is noticed for catechol and caffeic

acid. In all the assays no phenolic compounds degradation was observed, particularly when more easily degradable carbon source, such as glucose, is still present in the medium.

In order to investigate the influence of a pre-adaptation phase of cells to a phenolic medium, assays were conducted in Erlenmeyer flasks, as described above. It was observed that the phenolic compounds degradation was not improved, suggesting that the pre-adaptation phase used was not efficient to induce the metabolism of *C. cylindracea* CBS, *Y. lipolytica* W29 and *C. rugosa* CBS strains.

Respirometric assays

The toxicity of phenolic compounds and OMW on the activity of *Y. lipolytica* cells was evaluated through respiratory activity. The measurement of the oxygen uptake rate due to carbon source oxidation gives the fraction of the cells that are active. Figure 3 shows an example of the respiratory profiles of a cellular suspension with and without an injection of carbon source. The slope of linear decrease in the air saturation percentage represents the OUR.

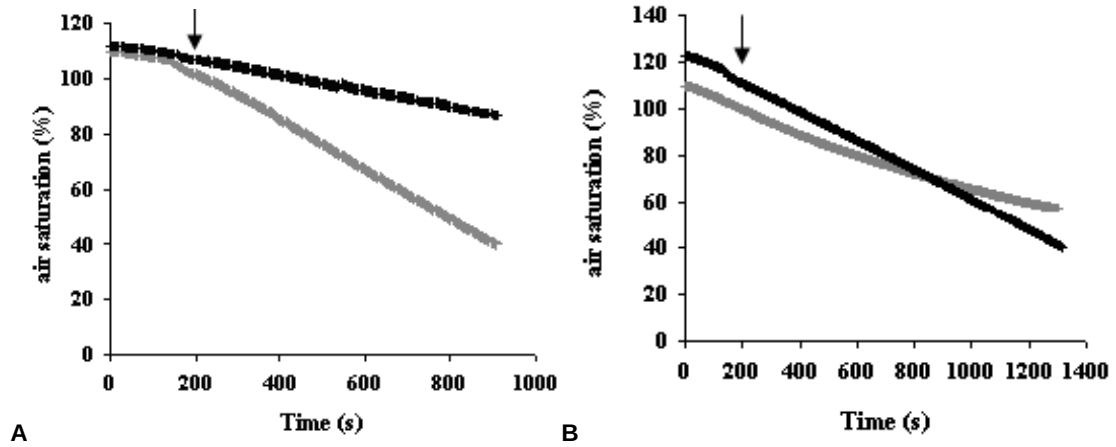

Figure 3. A - Air saturation percentage curves of a *Y. lipolytica* suspension (+) and cellular suspension with injection (+) of OMW (A) or catechol (B). The arrow represents the injection of carbon source.

The injection of a carbon source in cell suspension increase the oxygen uptake rate comparatively to that found in the assay without this addition, as proved with the injection of OMW. However, the addition of catechol to *Y. lipolytica* suspension leads to an inhibitory effect in the respiratory activity of this strain. The respiratory activity factor (RAF) for the different carbon sources was also determined and it was defined as a ratio between the total and the endogenous respiration rate (Table 2).

Table 2. *Y. lipolytica* respiratory activity factor (RAF) with different carbon sources

	Glucose	Phenolic solution	OMW (COD)	Catechol
Concentration/($g \cdot L^{-1}$)	0.48	0.83	3.8	0.63
RAF	2.01	2.24	3.09	0.82

It was observed that the injection of OMW and phenolic solution, without catechol, improved the total respiration rate even more than glucose. However, catechol injection leads to a respiratory activity inhibition.

The loss of activity factor was determined for assays with 30 min of catechol incubation and injection of glucose. The loss of activity obtained was, approximately, 99.6% for a concentration of catechol of 0.32 $g \cdot L^{-1}$.

Conclusions

The phenolic extracts obtained from the OMW have a large number of phenolic compounds, but these are mainly rich in hydroxytyrosol. The recovery of this important compound is improved in the solid-liquid extraction procedure, compared to that obtained by the liquid-liquid extraction methodology.

The less toxic compound, hydroxityrosol, is the most abundant in both OMW but there was no significant inhibition by the other phenolic compounds existing in the OMW. Thus the OMWs collected could be used by the lipolytic strains studied (*C. rugosa* PYCC 3238, *C. cylindracea* CBS 7869, *C. rugosa* CBS 2275, *Y. lipolytica* CBS 2073, *Y. lipolytica* W29 ATCC 20460 and *Y. lipolytica* IMUFR).

From the studied concentrations, no evidences of *Y. lipolytica* respiratory activity inhibition, by OMW and it's phenolic compounds, was observed. However, the results for catechol solution proved that exist considerable inhibition to yeast culture by this compound.

Topic: Integration of life sciences and engineering

Abstract

The stability of the bacterial community of an oil refinery treatment system was monitored over the course of 34 days, along with phenol shock loading. Changes in the bacterial community were monitored by denaturing gradient gel electrophoresis (DGGE) of polymerase chain reaction (PCR) that amplified 16S rRNA gene fragment. It was used a submerged membrane bioreactor (SMBR) operating with constant flux. During the operation, long-term high organic loading rates were applied in the SMBR by feeding blends of the oily stream with a high strength phenolic wastewater, also generated in petroleum refineries. During the operation, long-term high phenol loading rates were applied in the SMBR. Initially it was applied a high phenolic load (mean value of 85 mg L^{-1}) for a period of 18 days and a subsequent period of 16 days with low phenolic load (mean value of 15 mg L^{-1}). A quality of the effluents from phenol shock loadings was consistently high with respect to phenol ($\leq$ 85 mg L^{-1}) indicating efficient removal of 98%, along to the operation process. The analysis by PCR-DGGE indicated that the bacterial community has been able to adapt to the changes in environmental conditions and showed a relative stability, despite of the changes during the process in its microbial diversity that showed a coefficient of similarity exceeding 57% (Cs = 57%) throughout the process. The efficiency of phenol removal in SMBR (over 98%) associate to the stability of bacterial community, mainly in the ultimate phase of the process, was decisive to confirm that the bacterial community of sludge in SMBR was able to adjust in response to perturbations to sustain high effluent quality.

1 Introduction

Petroleum refinery wastewaters have a wide range of chemical compounds that are toxic to the environment. Phenolic compounds have remarkable importance as pollutants in refinery wastewater, since they are highly toxic for human beings, fishes and also impair several biochemical functions. Development of methods for phenol removal from industrial wastewaters has generated significant interest since phenols and other aromatic compounds play an important role as sole carbon and energy source of several microorganisms. The phenol concentration can be accepted as an indicator of the removal efficiency of pollutants

compounds from industrial wastewater, in particular, effluent of refinery (Margesin et al. 2005).

Although the conventional wastewater treatment plants normally produce good results, the conventional activated sludge processes involved are unlikely suitable to tackle with drastic flow rate and/or large composition variation. For those reasons, biological treatment of phenol is generally preferred to physical or chemical treatments mainly due to lower costs and the possibility of complete mineralization *(*Jiang et al. 2004). Activated sludge of aerobic wastewater treatment plants consists of a complex mixture of microorganisms that are either generalists or specialists. For years, researchers have examined the microbial populations of these activated sludge communities in order to understand their specific biological processes (Amann et al.1998).

Development of cost-effective manufacturing of membranes and increasingly stringent regulations for the discharge of effluents has accelerated the application of membrane technology of wastewater treatment and reuse. Membrane bioreactors (MBR), due to their higher biomass concentration, are able to deal with shock loadings and also to produce permeate suitable for reuse (Qin et al. 2007).

Studies on the effects of shock loadings in MBR treating industrial wastewaters are rarely reported in the literature, especially considering oil refinery wastewater treatment. Even for other activated sludge processes, there are few works concerning shock loading effects, although some studies reported phenolic wastewater degradation (Hsien and Lin*,* 2005). Viero et al. (2008) studied the effects of organic shock loadings regarding to the organic matter, ammonia-nitrogen, and phenols removal efficiencies. The results proved the ability of the SMBR to tackle with high strength feed during long-term exposition achieving high phenols and ammonia-nitrogen removal efficiencies, even in such complex feed.

Recently, numerous cultivation-independent techniques have been developed in order to analyze bacterial community structures without the inherent biases of cultivation. These cultivation-independent techniques for bacterial community structure analysis have revealed extremely complex communities within wastewater treatment bioreactors (Amann et al. 1998).

In this study, we investigated the bacterial community structure in SMBR treating oil refinery wastewater during long-term phenol shock loadings. We used the denaturing gradient gel electrophoresis (DGGE) of PCR-amplified 16S ribosomal RNA (RNAr) gene fragments for this purpose. During the process the changes in bacterial community structure were evaluated concomitantly with the SMBR performance regarding to the removal efficiencies of phenol.

2 Material and methods

SMBR plant and refinery wastewater

The submerged membrane bioreactor (SMBR) used in this work was described previously and it was used in the same operated conditions (Viero et al., 2008). In brief the reactor consisted of a cylindrical acrylic tank with working volume of 4.4 L, where a membrane skein with $2.78\times10^{-2}m^2$ area and a porous stone diffuser were inserted. Operation was conducted by alternating filtration with air backwashing to maintain permeate flux constant. Activated sludge for seeding was collected in an oil refinery wastewater treatment plant, in São José dos Campos, Brazil, and sediment to reach total suspended solid concentrations around 10 g L^{-1}. The sludge was acclimatized for 33 days in the SMBR. The reactor was operated in three different conditions regarding to the wastewater. The first one refers to the adaptation of the sludge to the operational condition, where the average concentration of phenol in the feed was around $15mgL^{-1}$ and was always less than 35 mg L^{-1}. In the second and third phases, average feed contained phenol concentrations of 85 and 15 mg L^{-1}, respectively.

Activated sludge samples

The SMBR was sampled throughout a 93-day period, with more frequent sampling from the 34 to 90 day. In the day 34, a sample of the activated sludge was collected to characterize the 'native' sludge (NS) acclimatized to the SMBR. During the high loading rate shock, activated sludge samples were collected every day and at the last phase, when the loading rate feed in the process was low, activated sludge samples were taken every two days. Samples for PCR-DGGE were colleted by centrifugation at 2,000 X *g* for 15 min and the pellet stored at -20^{o}C for DNA extraction.

Removal of phenol

The permeate values of phenol concentration were evaluated with the R-8012 kits used as recommended by the manufacturer (Chemetrics, Inc.).

DNA extraction from sludge samples

Genomic DNA from sludge samples was extracted according to the method described by Melvin and Hobson (1994) with some modifications. DNA was extracted from 0.5g (wet weight) sludge pellet that was resuspended in 1mL of TESC buffer (10mM Tris; 0.1mM EDTA; 0.1mM NaCl pH8.3). After 2 h incubation at –80ºC, 5 µL of DMSO (dimetyl sulfoxide) were added to the suspension and incubated again at room temperature for 1min. Subsequently, 500 µL of guanidine thiocyanate 5M and 500 µL of phenol:chloroform:isoamyl alcohol (25:24:1; v/v) were added. After centrifugation, the aqueous phase was transferred to a new tube and 30 µL of sodium acetate 3M was added. Total nucleic acid was precipitated from the aqueous extract with 2.5 volumes of 100% ethanol (-20ºC), dried, resuspend in sterile double distilled water and then stored at –20ºC.

PCR-DGGE analysis

Primers used in the PCR reactions were 968F (Nubel et al. 1996) and 1401R (Heuer et al. 1997) to amplify the V3 region of the Bacterial 16S rRNA gene. A GC-rich sequence attached to the 5'-end of primer 968F prevented the PCR products from completing melting during separation via DGGE. The PCR mixture contained 50pmol of the forward and reverse primers, 5µl of 10X PCR buffer, 0.2mM of deoxynucleoside triphosphates, 100ng of DNA template, 5U Taq DNA polymerase (Invitrogen), 0.1µM $MgCl_2$, and sterile deionized water to a final volume of 50 µL. PCR was performed following the program: an initial denaturation at 94ºC for 7 min, 25 cycles of 94ºC for 1 min, 60ºC for 1 min and 72ºC for 1 min, and final single extension at 72ºC for 7 min. PCR products were visualized by electrophoresis on 1.2% agarose gel after ethidium bromide staining. Amplicons of approximately 433bp were obtained and were analyzed by DGGE.

DGGE was carried out using a BioRad D-Code Universal Mutation Detection System. Samples containing approximately equal amounts of PCR amplicons were loaded onto 6% (w/v) polyacrylamide gels (38,9:1,1, acrylamide : bisacrylamide) in 1 X TAE buffer (20 mM Tris, 10 mM acetate, 1 mM EDTA, pH 7,4) using a denaturing gradient ranging from 45% to 65% (100% denaturant contains 7M urea and 40% (v/v) formamide). Electrophoresis was performed at 60ºC at 50V for 14h. Following electrophoresis, the gel was stained for 60 min with SYBR Green I nucleic acid gel stain (1:10.000 dilution; Molecular Probes, USA) and visualized/documented under UV light with the MiniBisPro (BioAmerica Inc.). DGGE fingerprints were manually scored by the presence or absence of co-migrating bands, independent of intensity. A dendrogram was constructed using the un-weighted pair group method with arithmetic averages (UPGMA). For these analyses, the NTSYS software package (version 2.02, Exeter Software, Setauket, NY, USA) was used. Pairwise community similarities were quantified using the Dice index (Cs) as: $C_s = 2\,j\,/\,(a + b)$, where *j* is the number of bands common to the samples **A** and **B**, and *a* and *b* are the number of bands in samples **A** and **B**, respectively.

3 Results and Discussion

Phenol removal and efficiency of reactor

Generally, the average phenol removal was higher than 98% for all phases of the operation; therefore when the feed had concentrations of less than 15mgL^{-1}, namely in the last phase, the phenol removal was superior to 99.3%. The efficiencies of phenol removal were similar to those reported in the literature, although the influent had significant concentrations of NH_4^+-N that could produce toxic effects and, then, reduce phenols and also organic matter removal efficiencies. Notwithstanding, the removal efficiencies were high considering the hydraulic retention time employed.

The results for phenol concentration in the permeate are under the limits specified by the Brazilian law for discharge of effluents (0.5mgL^{-1}) (CONAMA, 2005).

Bacterial communities analysis

Prominent bands were observed in the sludge samples during the overall process (Fig. 1). The pattern observed in the DGGE analysis indicates a presence of a wide variety species in the samples.

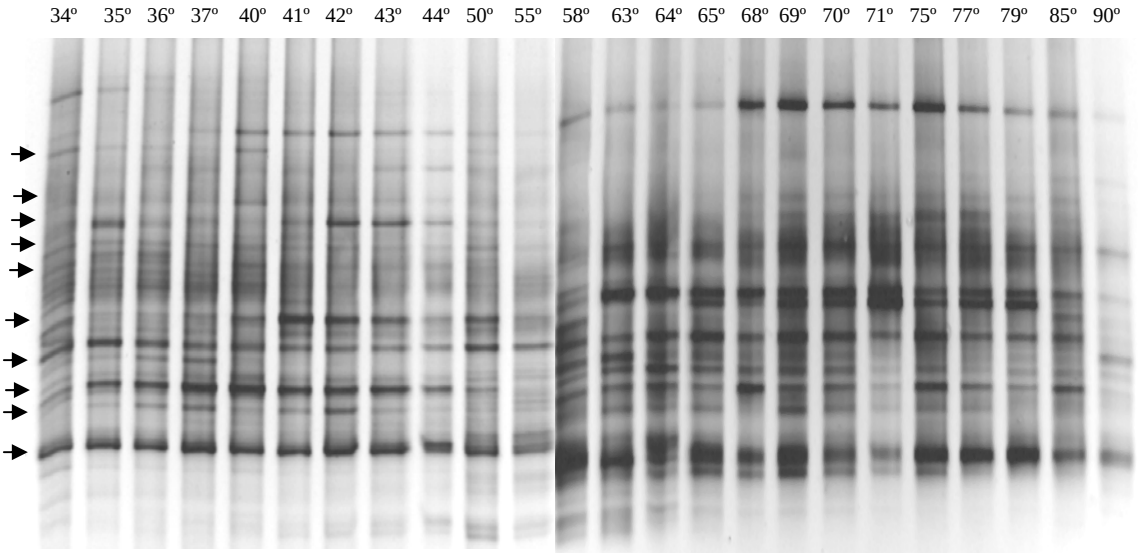

Figure 1: DGGE of PCR-amplified region 968F to 1401R of 16S rDNA from the SMBR bacterial communities. Lane labels along the top show sampling time (days) from startup of the shock loading process where high phenol shock loading were performed from 35 to 58 days (mean value of 85 mg L^{-1}) and low phenol shock loading, from 63 to 90 days (mean value of 15 mg L^{-1}). Solid black arrows identify bands found along the 90-days sampling.

It was identified 28 different bands along the samples, which were distributed in different forms in the sampling days. Analysis of DGGE profiles revealed changes in the bacterial community exposed to different concentrations of phenol. The diversity of the bacterial community was higher during the high loading rate shock (85 mg L^{-1}phenol) when compared the low loading rate shock (15 mg L^{-1}phenol), demonstrated by showing a superior number of bands.

The 'native' sludge sample and the 37 day's sample showed a higher number of bands, containing 89% of the total 28 detected bands. Some communities were preserved during the two phenol shock loadings as observed from the 35 to the 90 day. The high and the low phenol shock loadings samples showed an average of 72.9% and 51.5%, respectively, from the total number of bands. Although the samples collected during the 15 mg L^{-1}phenol shock rate loading (from 63 to 90-day samples) showed reduced number of bands, they should represent the most adapted microorganisms since they maintained their growth for the whole phenol shock loading periods.

Ten DGGE bands were found along the 90-days sampling (Fig.1). These bands may represent the long-term community structure with high stability and may have been responsible by the success of the SMBR, ensuring the efficiency of phenol degradation. Individual persistent species responsible for these bands would be likely candidates for

incorporation into a seed culture in order to improve bioreactors performance, particularly during startup of wastewater treatment

Other bands were found only at the first days of the phenol shock loading, demonstrating the toxic effects of phenol for certain microorganisms.

The hierarquical grouping of bacterial communities was performed by the NTSYS and is illustrated by the dendrogram in Figure 2. The bacterial communities from 'native' sludge and from the two-phenol shock loadings grouped in three different main clusters. The bacterial community structure during high phenol shock loading was divided in two clusters (I and II). They had similar community structures when compared to each other (Cs = 77%). The third cluster had slightly lower Cs value compared to the first one (Cs = 57%).

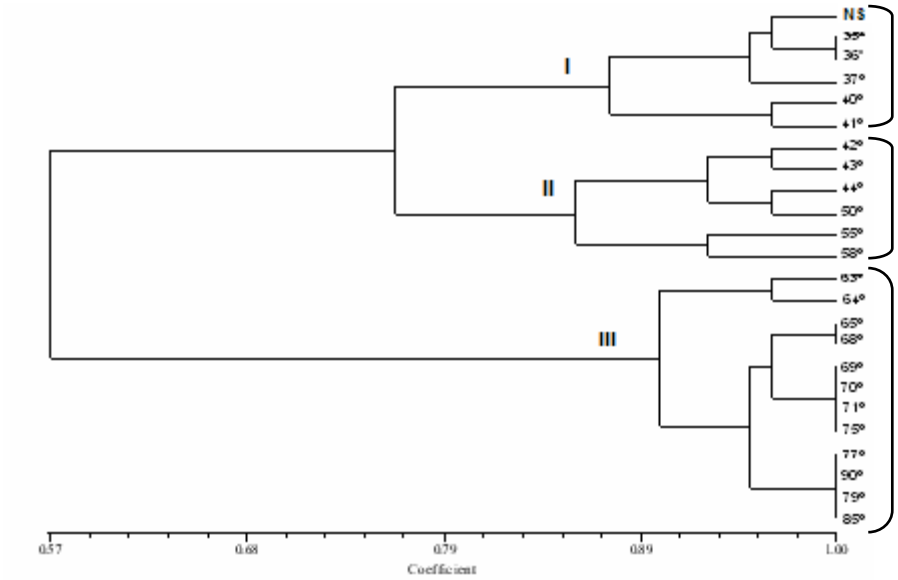

Figure 2: UPGMA analysis dendrograms of bacterial community DGGE fingerprints. Arabic numerals show the sample time (days), and roman numerals indicate major clusters.

Comparing the Cs index of the 'native' sludge with the last day of each phenol shock loading phase it may be noted that the community showed small shifts during the process. Thes last day during the high phenol shock loading (58 day) and a sample collected during the low phenol shock loading (90 day) presented a Cs regarding the 'native' sludge of 76.1% and 56.4%, respectively. At long of the whole period of high phenol shock loading, compounding 12 samples of sludge, it was obtained an index superior to 82.7%. The community stability between the 69th day and 70, 71, 75 and 77 days, and also between the 75th day and 79, 85 and 90 days may be evaluated by analyzing the Cs index, that was 100% for these days. These high Cs values confirmed the stability of the community on overall process, and showed the ability of the bacterial community to adapt to long-term phenol shock loading. During the high phenol shock loading it was observed a diminishment in the bacterial community diversity, and this may be explained as the proper toxicity of phenol towards microorganisms (Barrios-Martinez et al. 2006).

Conclusions

This work presents the tracking of bacterial community from an oil refinery wastewater treatment during phenol shocks, using PCR-DGGE analysis of the V3 region of the 16SrRNA gene. As observed, the bacterial community could adapt to environmental condition changes, a desirable characteristic, since the flexibility relationated to the bacterial community structure leads to more stable process performance (Fernández et al., 2000).

Functionally stable wastewater treatment reactor was maintained in response to varying effluent wastewater characteristics by a microbial community that adapted its structure to

sustain high effluent quality. The phenol efficiency removal was higher than 98%. PCR-DGGE can be considered a useful tool to evaluate microbial community structures in biological wastewater treatment reactors, indicating the changes on the microbial communities during the process and which communities is still presented along the entire operation. The persistent species in the long-term operation should be identified to be used as seed culture to improve bioreactors performance, particularly during startup of wastewater treatment.

Topics: Integration of Life Sciences & Engineering

Abstract

The increasing global scarcity of water it is imperative to develop technologies that permit to treat wastewater for its subsequent reutilization. The treatment of coloured wastewater from some manufacturing processes is a challenge due to the complex contaminants involved. White-rot filamentous fungi have shown their capacity to degrade molecules with high molecular weight that are analogous to their natural substrate, i.e., lignin, which are present in the effluents from wood pulp and paper mills, sugar refineries and olive oil plants, among others. The degradation mechanism is based on the action of extra-cellular enzymes that are synthesized and secreted by fungi during the secondary metabolism stage under limiting nutrient conditions. This ligninolytic system has also been successfully used in the degradation of synthetic dyes (1, 2).
The purpose of this study is to quantify the action of the extracellular oxidation system of *Phanerochaete chrysosporium* over multi-component coloured solutions in order to establish the potential degrading capacity in the effluent from a textile plant. Previous studies (3) determined, by means of screening, that the ligninolytic system of this fungus has a greater affinity for those azoic dyes containing naphthalene rings in their molecules. Based on these results, mixtures were prepared by selecting dyes for which the enzymatic system has shown a different affinity. This strategy would also lead to the prospect of evaluating possible synergic effects between substrates. For this purpose, fixed-bed bioreactors were used with immobilized biomass and feed with bi-component mixtures of textile dyes: acid (Acid Black 1 and Acid Orange 6), basic (Basic Violet 4 and Basic Blue 24) and reactive (Reactive Blue 19 and Reactive Orange 16). The biological unit was feed in increasing steps with equimass mixtures at varied concentrations.

Introduction

Environmental pollution caused by hazardous waste containing recalcitrant xenobiotic chemicals has become one of the major ecological problems. Unlike the naturally occurring organic compounds that are readily degraded upon their discharge into the environment, some of these synthetic chemicals are extremely resistant to biodegradation by native microorganisms. In particular, synthetic dyes are extensively used for textile dyeing, paper printing and colour photography, and as additives in petroleum products. During the dyeing process, 10–15% of dye is discharged into the effluent. Approximately half of all well-known dyes are azoic, representing the largest group of synthetic colorants. Azo dyes and their pigments are versatile and are therefore the synthetic colorants that are most released into the environment. Their structural modification is also possible and they can be caused to bind with most synthetic and natural textile fibres.
Studies related to biodegradability of dyes using white rot fungi (WRF) are extensive and include reports on living and dead cells. In the case of living cells, the major mechanism is the biodegradation caused by the lignin-modifying enzymes (LME) which mineralize synthetic lignin or dyes. For dead cells, the mechanism is biosorption, which involves physical-chemical interactions, such as adsorption, deposition, and ion-exchange (4).
WRF produces a variety of extracellular lignin-modifying enzymes (LiP and MnP) (5, 6, 7) and phenol-oxidase enzymes such as laccase (8) which are related to the degradation of lignin. A new peroxidase, called versatile peroxidase (VP), was found in active lignin-degrading strains of *Pleurotus eryngii*. This peroxidase combines catalytic properties observed in LiP and MnP of *Phanerochaete chrysosporium* (9).
Numerous researches have been reported regarding the decolorizing and/or degradation of dyes with different chemical structures as well as, using diverse treatment alternatives. In particular it has been proved the capacity of degradation *in vivo* and *in vitro* of *Phanerochaete chrysosporium*, using static, agitated and continuous systems (10, 11, 12, 13, 14). In the continuous systems the analyzed substrata are diverse and the used microorganisms are fundamentally fungi. The studied dyes are

[1] Corresponding author. Tel + 562-7181835. E-mail:andrea.carvajal.g@gmail.com

triphenylmethane, azoic, ftalocianine, anthraquinone as well as also, textile effluents (14, 15). In more recent studies (3) promissory results have been obtained using continuous reactors with biomass immobilized in foam of polyurethane to decolorizing and/or to degrade azoic dyes.
The later application of this technology for the treatment of the industrial effluent must have in consideration that the waste water contains varied pollutants. In particular in those originated in the textile processes there is more than one dye. From this perspective it is important to establish the effect that the different dyes of the mixture might have on the degradation (decolorization) of each of them. In this context the goal of present study is to analyze the degradation of mixture of dyes of acid, basic and reactive type in the bioreactor with immobilized *Phanerochaete chrysosporium*.

Materials and Methods

Microorganism: *Phanerochaete chrysosporium* BKM-F-1767 (ATCC 24725) was kept at 4ºC in malt extract plates (16).
Dyes: The dyes selected for the study, of analytic quality and given by Sigma S.A., as well as their characteristics are presented in the Table 1.

Table 1. Characteristics of dyes

Dye	Cromophore	λ (nm)	Structure
Acid Black 1 (AB1)	Diazoic	618.5	Acid Orange 6 (AO6)	Azoic	390.0	Basic Violet 4 (BV4)	Triphenylmethane	595.0	Basic Blue 24 (BB24)	Thiazine	633.0	Reactive Blue 19 (RB19)	Anthraquinone	592.5	Reactive Orange 16 (RO16)	Azoic	493.0	
Culture immobilized: The preinoculate was prepared in a Fernsbatch (2 l) which contained 10-12 plugs (5mm in diameter) as an inoculate with 100ml of culture medium, and was incubated at 37ºC for 2d. The medium composition was $10g \cdot l^{-1}$ of glucose, 2.2mM of ammonium tartrate, and $100ml \cdot l^{-1}$ of BIII mineral medium (17) in sodium acetate (20mM) as a buffer (pH 4.5). The medium was autoclaved and then a filter-sterilized thiamine solution ($400mg \cdot l^{-1}$) was added ($5ml \cdot l^{-1}$). The mycelium that formed on the surface was homogenized and inoculated in a 10%(v/v) proportion in Erlenmeyer flasks (250ml) which contained 81ml of culture medium (described above) and 1.8g of immobilization support. These support consisted of polyurethane foam cubes of $0.125cm^3$ with a density of $20kg \cdot m^{-3}$. The cultures were incubated at 37ºC in an orbital agitator, at 150r.p.m. After inoculation and every 24h afterward, the cultures were oxygenated with pure O_2 for 3min using a pressure of 0.8bar. After 3 or 4d two Erlenmeyer flasks with the colonized foam were transferred as inoculate to the bioreactor.
Bioreactor operation: The medium feed to the bioreactor consisted of: $5.75g \cdot l^{-1}$ glucose, $0.0144g \cdot l^{-1}$ ammonium tartrate, $16.4g \cdot l^{-1}$ sodium acetate as buffer (pH 4.5), $0.0056g \cdot l^{-1}$ Mn^{+2} as $MnSO_4 \cdot H_2O$, $100ml \cdot l^{-1}$ BIII and $5ml \cdot l^{-1}$ Tween 80 (15, 17). This culture media was supplemented by the previously sterilized mixture of dyes, with the global concentration varying from 20 to 160; 20 to 240 and 10 to 60 $mg \cdot l^{-1}$ for acid, reactive and basic dyes, respectively. The bioreactor was operated with a hydraulic retention time of 24h (18) and flow rate of $8.4ml \cdot h^{-1}$. The system was oxygenated by a pulsed flow of gaseous O_2 applied with a frequency of $0.0625s^{-1}$. The temperature was kept at 37°C by water circulating at the jacket of the bioreactor. Two samples of the culture media were taken every 24h, the first at the bottom and another at the top of the column during the whole operation period.
Enzyme activity and analytical assays: MnP activity was measured by the oxidation of 2.6-dimethoxyphenol at 468nm (19). LiP activity was assayed against veratryl alcohol as was described by Tien and Kirk (1988).

Dye decolourization was monitored by the reduction absorbance spectrum of the mixture dyes between 380 and 750nm. The spectrum was adjusted to a polynomial equation using the Curve Expert v1.3® program. Integration of this function permitted to estimate the decolourization degree reached day by day. The absorbance spectra of each of the three formulated dye mixtures are shown in Figure 1.

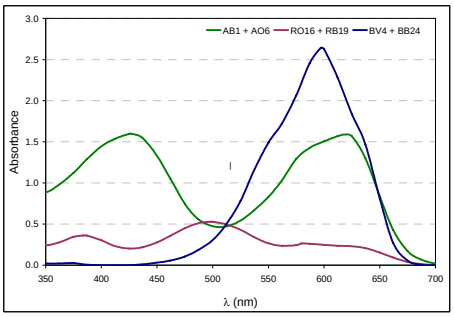

Figure 1. Absorbance Spectra of Mixture Dyes.

Results

Figure 2 shows the results obtained to the operation of bioreactor with the mixture of dyes. In all of them is observed that after 8 days of continuous operation, the feeding of the bioreactor was supplemented with dye. For the basic dyes (Figure 2a) the decolourization assay began with a total concentration of mixture of dyes of 10mg·l^{-1} and an average level of activity of 60U·l^{-1}, which droops temporarily after the injection. From day 15 the value of specific activity doubled, when the amount of dye was also doubled. Later the activity shows a continuous increase observing peaks in days 19 and 25 (240U·l^{-1}) in circumstances that the system is operating with a dye concentration of 40mg·l^{-1}. Finally a dye concentration of 60mg·l^{-1} caused the drop of the expression of MnP activity up to zero, inhibiting completely the enzyme production. On the other hand, the monitoring of the decolourization process began the day 14, reaching an absorbance reduction of 91%. This value stays practically constant until the day 25. Later, from the day 32 a continuous decrease of the decolourization was observed up to 40%.

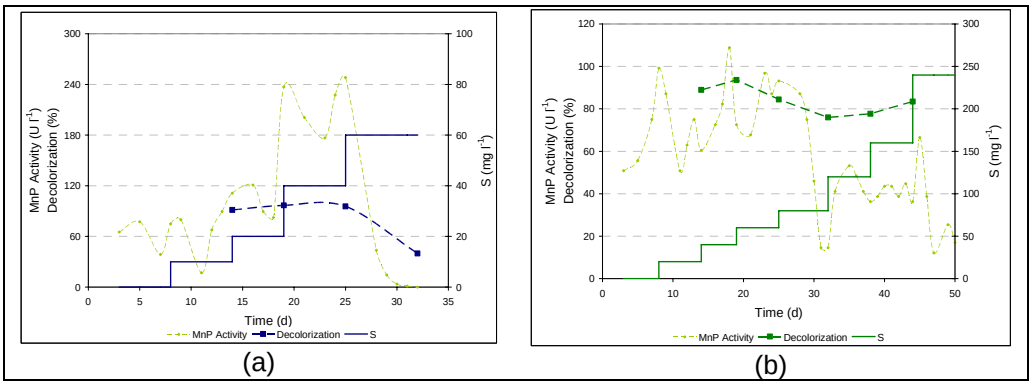

Figure 2. Decolourization of mixture and enzymatic activity in bioreactor of basic (a) and acid (b) dyes.

The Figure 2b shows that during an activity peak (100U·l^{-1}), started to supplement the culture medium with a total concentration of the acid dyes of 20mg·l^{-1}, the addition caused a rapid descent of activity up to 60U·l^{-1}. Later a fluctuating increase is observed up to reaching an activity peak of 110U·l^{-1} in the day 18, period in which the reactor operates with 40mg·l^{-1} of dye. Between the days 20 and 30 the average activity remained in 90U·l^{-1} in circumstances that the dye concentration was increased step by step even 80mg·l^{-1}. Later increases of the concentration to 120 and 160, produces a fluctuating activity level around 40U·l^{-1} until day 48 and after it diminished to 20U·l^{-1}. The monitoring of the decolourization process began on day 12, reaching an absorbance reduction of 90% up to the day 20. Finally this value diminishes up to 80% on day 25, staying constant to the final operation time of the reactor that was of 50 days.

In the Figure 3a is possible to observe that the addition of reactive dyes started when the activity had a value of 70U·l^{-1}. The activity profile shows subsequent increases until the 13' day with a peak of 155U·l^{-1}. Between days 18 and 30, the activity fluctuation was between 90 and 120U·l^{-1}, in this point the concentration was 80mg·l^{-1}. When that concentration was increased to 120mg·l^{-1}, the average activity decreases to the initial value (60U·l^{-1}).

Against continuous increases of concentration values of 160 and 240 mg·l^{-1} it decreased constantly to values around zero on day 50. Decolourization of 80% (on day 14th) augments and then stabilizes on 90% until day 38. Finally it decreases with constant rate to 60% on day 50.

On global terms the system shows a fluctuating behavior on the production of MnP. The maximum levels of activity are 50% of those reached with the basic dyes (120 vs. 240U·l^{-1}, on both cases between 40 and 60mg·l^{-1}), and the expression of activity is more stable. This could indicate that the capacity of the acid dyes to induce the production of MnP is achieved on minor concentrations that those that are observed for the basic dyes, the specific activity values achieved are lower. The reactive dyes induce the synthesis of MnP, showing temporary decreases of activity after each increment of concentration.

The addition of the dyes to the feeding media of the biological units caused a decline of the enzymatic production after each increment of the concentration. In some cases, as can be observed for the basic dyes, low concentrations can be inhibitors (40mg·l^{-1}), unlike the acids and reactive dyes. The generation of coloured compounds sometimes named coloured derivatives, generated through the partial rupture of the dye structures, can be the responsible of the cellular metabolism inhibition. The half-life of the coloured derivatives can affect in this fact.

On the other hand, the generation and/or additional contribution of nitrogen compounds that can be assimilated by the microorganism could result in a reversed secondary metabolic process, favouring growth to the benefit of the expression. Such a hypothesis would have to be proved by quantifying the biomass and/or concentration of total N in the effluent.

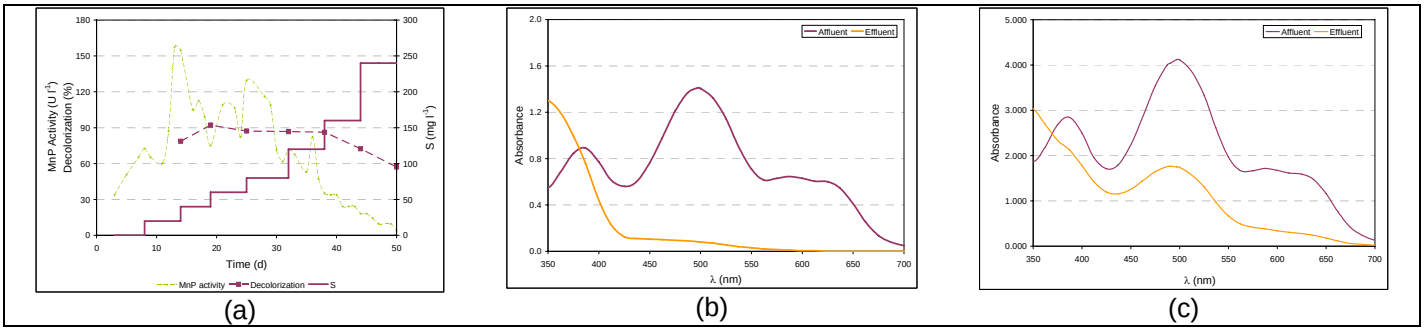

Figure 3. (a) Decolourization of mixture and enzymatic activity in bioreactor of reactive dyes. Bioreactor affluent and effluent absorption spectrum (b) 80mg·l^{-1} and (c) 240mg·l^{-1}, reactive dye.

The Figure 3b shows as an example, the significant reduction obtained for the typical absorbance's peak of the reactive dyes in the mixture when the feed concentration was 80mg·l^{-1}, also was not observed generation of coloured derivatives. Only for the highest concentration of the reactive dyes (240mg·l^{-1}), whose results are presented in the Figure 3c, and basic dyes (60mg·l^{-1}) was not observed the completely reduction of the peaks of maximum absorbance. Under these circumstances the decolourization might be awarded to the adsorption in the mycelium or support, which is concordant with the inhibition observed for the enzymatic system (20).

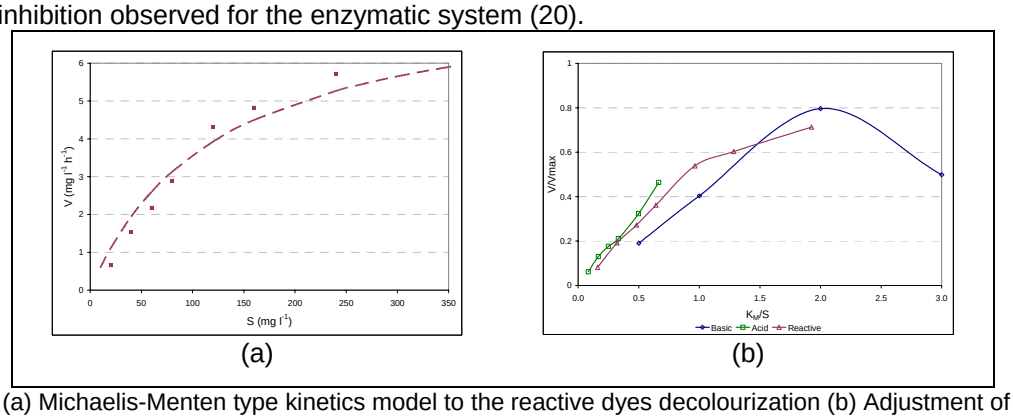

Figure 4. (a) Michaelis-Menten type kinetics model to the reactive dyes decolourization (b) Adjustment of the non-dimensional kinetic model for dye mixtures.

The data decolourization (%) versus substrate concentration was satisfactorily interpreted by the classic Michaelis Menten model (Figure 4a), resulting in a half-saturation constant of 124.6mg·l^{-1}, and a maximum velocity of 8mg·l^{-1}·h^{-1} (R^2=0.949). The mixture of acid dyes had a similar kinetic behaviour, while basic dyes showed an inhibition effect.

Figure 4b shows the dependence of non-dimensional variables V/Vmax versus K_M/S. It also shows that for K_M/S values that are higher than the unit, the system operates with concentrations above K_M.

Both mixtures of acid and reactive dyes show non-saturation regarding these alternative substrata, indicating the feasibility of exploring higher substrate concentrations. Conversely, for basic dyes with a lower K_M value than those referred to above, results imply that a high decolourization level may be reached at low concentrations. However, from a concentration with double K_M value, the system becomes inhibited showing a low affinity of the enzymatic system to these substrates.

Table 2 shows a summary of the kinetic parameters resulting from adjusting a Michaelis-Menten type model.

Table 2. Characteristic parameter of each mixture

	Basic	Acid	Reactive
v_{max} mg·l^{-1}·h^{-1}	2.000	12.000	8.000
K_M mg·l^{-1}	24.610	240.836	124.630
1/ki mg·l^{-1}	0.003	-	-
R^2	0.602	0.935	0.949

Discussion

The present study analyzed a continuous decolourization strategy realized in the fixed bed reactor with immobilized biomass. The purpose to perform the continuous assays with increasing dyes concentration steps is to evaluate the adaptability of the biological system against the different chemical structure of the dyes as alternative substrate. The minimum period for the increasing of the concentration was established in 4 times of the hydraulic retention times (24h). The global decolourization of mixture dyes and MnP activity was considered as response variables which evolution are shown in the Figure 2 for the basic (BV4 - BB24), acid (AB1 – AO6) and reactive (RB19 – RO16) mixtures. On it can be observed that for all assays MnP activity was detected between the days 3-5 before the culture medium was supplemented with dyes reaching 60U·l^{-1}. During decolourization processes MnP activity was only mayor ligninolytic activity detected.

Later to the first addition of dyes the level of MnP activity increased obtaining an activity peak of 240, 150 and 110U·l^{-1} for the 40mg·l^{-1} of basic (Figure 2a), acid (Figure 2b) and reactive (Figure 2c) mixture dyes, respectively. Nevertheless the enzyme production was fluctuating, showing activity descents whenever the dyes concentration increased.

In global terms the activity shown a tendency to increase when the dyes concentration increased which might be explained by the enhancing role of dyes or they by-products on ligninolytic enzyme production, effect reported recently for the laccase production by *P. ostreatus* (21). Wherever the accumulation of intermediates compounds (aromatic amines for example) of degradative processes, it might be a cause to the variable MnP activity levels for the metabolism partial inhibition. Finally it takes place the growth total inhibition to basic (day 30) and reactive (day 50) dyes for 60 and 160mg·l^{-1} respectively. The reactor operated with a mixture acid dye even shows residual MnP activity de 20U·l^{-1} in the day 50.

Higher decolourization was observed for all assays from the 12th-15 day (up to 85%-90%) dropping from the 25th, 38 and 32 day up to 40% (basic dyes), 60% (reactive dyes) and 80% (acid dyes) respectively.

The kinetic analysis of the experimental data obtained during 30-50 days of operation showed the feasibility of operating at higher concentrations than K_M estimated by adjusting a Michaelis-Menten type model for acid and reactive dyes. On the contrary, for basic dyes, a concentration that is double the K_M causes the total inhibition of the fungal system.

By reviewing the values shown in Table 2, it is possible to establish the lower decolourization capacity of the basic dyes as compared to the acid or reactive dyes, as their continued characteristics have a lower value. The determination of the kinetic parameters allows the establishing of the ranges of dye concentration that must be evaluated in order to keep the bioreactor stability (22). It should be mentioned that the treated two-component mixtures had a dye that was labile against the degrading action of the (AB1, RO16, BB24) enzyme, and another dye regarding which the enzyme showed little or zero affinity (AO6, RB19, BV4) (3). Thus the results obtained showed a synergic effect on the decolourization capacity, as it was possible to degrade dyes to which the enzymatic system had not shown affinity at individual level.

Conclusion

The ability of *P. chrysosporium* to survive up to more of 30 days and make a decolourization of a mixture of dyes simultaneously during the sequential step with increasing dyes concentration is an adaptive feature that makes of this strategy a feasible option for an effective removal of synthetic dyes from wastewater.

Topic: Integration of life sciences & engineering.

Abstract

This work describes the optimization of industrial textile dye colour removal environmental conditions by Pseudomonas oleovorans. A pre-culture of *Pseudomonas oleovorans* in late exponential phase or early stationary phase was inoculated in tubes containing Nutrient Broth with dye where a factorial experimental design was performed. The variables used in the factorial design (2^{n-2}) were dye concentration (30, 50, 70 mg L^{-1}); agitation (0, 75, 150 RPM); initial pH (6.0, 7.0, 8.0); temperature (27, 32, 37 °C); time (36, 48, 60 hours); tube volume (25, 50, 75%); and initial culture size (0.5, 1.0, 1.5 O.D.). It was observed that decolourization of the industrial dye was negatively influenced by the tube volume and the dye concentration, which should be related with the maximum capacity of the strain to decolourize azo dyes. Time and temperature affected the decolourization positively, although they were not significant. The best conditions to dye decolourization by *Pseudomonas oleovorans* based on the experimental design and also economic factors were agitation 0 RPM, pH 8.0, temperature 32 °C, 25% of tube volume, initial culture size of 0.500 abs, dye concentration of 50 mg L-^{1}.

1 Introduction

There are more than 100,000 commercially available dyes with over than 7 x 10^7 tons of dyestuff produced annually worldwide (Akhtar et al., 2005; Robinson et al., 2001). In Brazil, alone, 26,500 tons are produced (Ulson de Souza et al., 2007).Thus, as result of large production and consumption of dyes, serious environmental problems have been attracted extensive concerns (Wesenberg et al., 2003; Yang et al., 2008).

The elimination of dye containing effluents is mostly based on physic-chemical procedures (e.g. adsorption, concentration, chemical transformation and incineration) (Ramya et al., 2008). These methods are rather costly and sometimes produce hazardous by-products and therefore raise other environmental problems. One attractive strategy is bioremediation, which is becoming an important issue in both developed and developing counties (Wafaa et al., 2003).

It has been observed that some microorganisms can transform azo dyes into colourless products. Bacterial degradation of azo dyes is often initiated by an enzymatic step that involves cleavage of azo linkages with the aid of an azoreductase (Yeh and Chang, 2004). The bacterial ability to decolourize dyes has been reported by several researchers (Barragan et al., 2007; Khalid et al., 2008; Lodato et al., 2007; Mohana et al., 2008; Pandey et al., 2007), although, less attention had been given to conditions optimization for colour removal of contaminated effluents.

Statistical design of experiments is a widely used methodology in upstream and downstream processing (Kammoun et al., 2008; Khosravi-Darani and Zoghi, 2008; Porto et al., 2008), in which differ from the classical optimization methods. The further methods involve single factor variation, keeping the other factors constant. Otherwise, this method is not suitable for multifactor optimization not only because it is time-consuming but also because it is unable of detecting the true optimum due especially to the interactions between the factors (Kammoun et al., 2008; Liu and Tzeng, 1998). To avoid these problems, statistical design of experiments is used. Such designs require a relatively small number of runs per factors allowing the identification of the most important variables and its optimum ranges, as well as the experimental verification of these identified optimum (Weuster-Botz, 2000), the designs can also indicate a promising direction for further experimentation (Lim and Lee, 2008).

This work describes the first step on the optimization of environmental conditions for decolourization of industrial dye by *Pseudomonas oleovorans* in submerse cultures.

2 Materials and Methods

The microorganism was obtained from the collection of the Brazilian Collection of Industrial and Environmental Microorganisms (CBMAI) of the State University of Campinas, previously identified as *Pseudomonas oleovorans* (CBMAI 703).

The strain was preserved in cryotubes containing glass beads and 10% glycerol (v/v). Each crytube was loaded from the same initial culture and had and average of 30 beads. It was thus possible to use the same cell generation for all experiments.

The industrial textile dye was obtained from the kind permission of Clariant of Brazil (Sao Paulo, Brazil). As it is for commercial use, the name, C.I. number and name, and molecular structures will be omitted further in this study. All other reagents are of analytical grade.

For each experiment, an Erlenmeyer flask containing 20 ml of Nutrient Broth (meat extract 3 $g \bullet l^{-1}$ and peptone 5 $g \bullet l^{-1}$) was inoculated with a single glass bead from the same cryotube and incubated at 28 °C for 24 hours when an early stationary phase or final exponential phase was reached.

The influence of variable, namely Temperature (°C), pH, Dye Concentration ($mg \bullet l^{-1}$), Agitation (RPM), Volume (%), Culture Time (hours) and Inoculum Size (O.D.), on the two selected responses, namely Decolourization (%) and Biomass ($g \bullet l^{-1}$), was evaluated from the result obtained from a 2^{7-2}–factorial design plus a central point, which was run in triplicate to allow estimation of pure experimental error. The values selected for these variables are listed in Table 1. All statistical and graphical analysis were carried out with the Statistica 8.0 package (Statsoft Inc., Tulsa, OK, USA).

The decolourization experiments were carried out in screw-topped tubes containing liquid medium as described previously, but also contained the dye concentration, tube volume, inoculum size and pH listed in Table 1. The dyes were filter-sterilised prior to addition to the sterile culture medium. The tubes were incubated under anoxic conditions away from light. Control experiments were performed using the same medium with microorganisms.

The samples from the decolourization cultures were collected and analysed following the methodology described by(Chen, 2002) as follows:

1) OD_{600nm} of the sample mixtures without centrifugation;

2) OD_{600nm} of sample supernatant after centrifugation for 10 minutes at 10,000 g; and,

3) OD_{609nm} of sample supernatant after centrifugation.

The biomass produced was determined by subtracting the value obtained on the first step from the value obtained on second. Colour removal efficiency was determined by the following equation:

$$Decolourization = \frac{A_{\lambda,initial} - A_{\lambda,final}}{A_{\lambda,final}} \quad (1)$$

in which $A_{\lambda,initial}$ is the absorbance before the decolourization process and $A_{\lambda,final}$ is the value obtained on the third step.

3 Results and Discussion

The responses obtained from the 35 runs of the fractional experimental design are listed in Table 1. It was observed that the tube volume was the most influenced variable with a negative response. Negative effects were observed in the volume, dye concentration and inoculum size in the decolourization of the industrial dye. Nevertheless only the inoculum size was not significant to the decolourization. The summarizations of variables' significances are listed in Table 2.

[a] – temperature (°C); [b] – dye concentration ($mg \bullet l^{-1}$); [c] – agitation (RPM); [d] – volume (%); [e] – time (hours); [f] – inoculum size (O.D.); [g] – decolourization (%); [h] – biomass ($g \bullet l^{-1}$); * – central point repetitions

The decolourization of the industrial dye was negatively affected by the tube volume and dye concentration; this should be explained by the overall mass of industrial dye in the medium. Industrial dyes generally contains one, or more sulphonic-acid groups on the aromatic rings and may affect the DNA synthesis, since it has been reported that dyes are inhibitors of nucleic acid synthesis, or cell growth (Chen et al., 2003). Furthermore, the biomass production is also negatively effect by the dye concentration.

This also suggests that the medium's dissolved oxygen, as well as the available oxygen within the tube, has a limiting role in the beginning of decolourization process, since it competes with the azo bound as an electron receptor. Once extinct, and when the redox potential is reached, the effective dye decolourization begins (Bromley-Challenor et al., 2000)

Table 2 –Estimated effects of studied parameters (t distribution)

[a] – $p < 0.05$

Table 2 also shows that, although the agitation has a positive effect on decolourization and biomass production, this effect is little influent over industrial dye decolourization process. Since this study aims an industrial application, the lack of agitation, even in anoxic condition, which deals only with mass transfer rate, is not advantageous.

The industrial dye reduction in anaerobic or anoxic conditions is an extracellular and non-specific process (Kalme et al., 2007), and usually occurs through an enzymatic reaction. This should explain the correlation between biomass production and decolourization as shown in Figure 1.

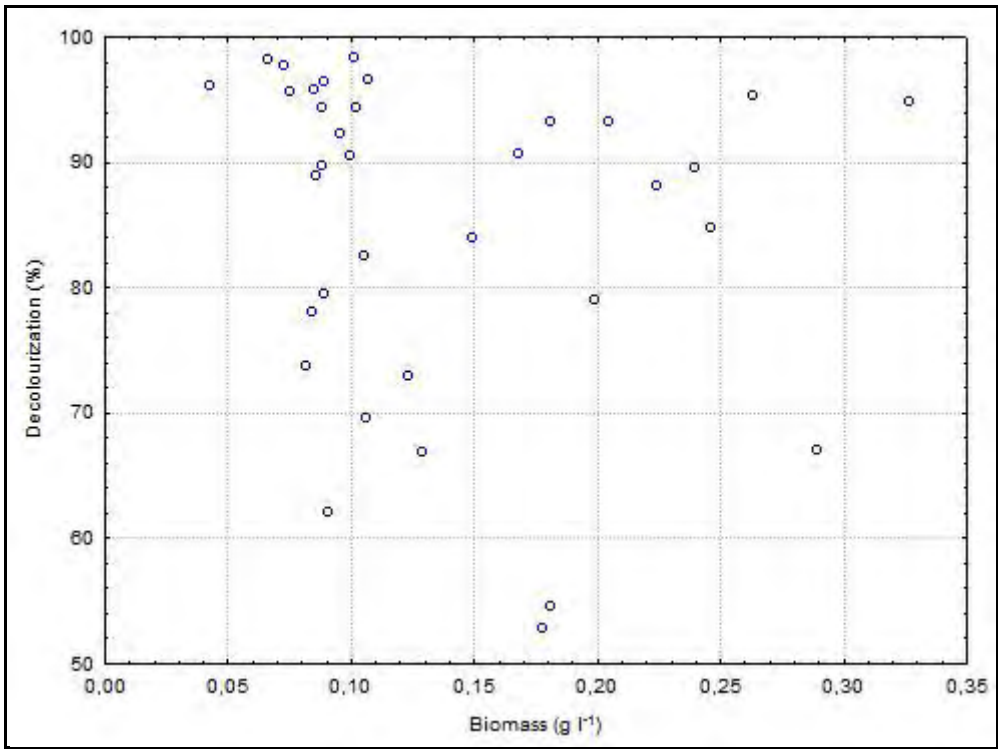

Figure 1 – Decolourization as a function of biomass production

In their studies performed with *Kurthia* sp., Sani and Banerjee (1999) observed that the increased biomass production resulted an increase of triphenylmethane dyes decolourization. They observed that there is a limit to the maximum efficiency of colour removal could be reached. The same was observed with *P. oleovorans*, although its point of best efficiency related on the biomass production and colour removal rate is not the point were there was the major biomass production.

The increase of pH, from an acid pH to a slight basic pH, showed an increase of decolourization, even though it was not significant. Pearce (2003) described that bacterial cultures usually have maximum decolourization rates at neutral pH or low basic. The increase of temperature also showed an increase on decolourization, probably due to enzymatic activity increase, however it is not significant. The culture time showed to affect positively the dye decolourization, with is explained by the longer exposition time of the dye to the enzymatic apparatus of the microorganism.

5 Conclusions

The best conditions to dye decolourization by Pseudomonas oleovorans based on the experimental design and also economic factors were agitation 0 RPM, pH 8.0, temperature 32 °C, 25% of tube volume, initial culture size of 0.500 Optical Density abs, dye concentration of 50 mg L^{-1}.

6 Acknowledjements

The authors would like to acknowledge Fapesp, Capes and CNPq for financial support; and Clariant of Brazil for the dyes provided.

Keywords: Eutrophication; Phosphorus removal; Polyolefin; Aluminum oxide
Topic: Integration of life sciences & engineering: Improvement of environmental remediation processes.

Abstract

Phosphorus is the main nutrient responsible for eutrophication of aquatic ecosystems, therefore it is important to develop new processes to remove phosphorus that avoid the formation of precipitates. Polyolefins with and without prior activation with aluminum oxide (Al_2O_3), processed as flat plates, were investigated for phosphate removal from an aqueous solution. The maximum amount of phosphorus removal was 0.042 μgP/cm^2 for PE (polyethylene), 0.049 μgP/cm^2 for PE-g-MA (polyethylene grafted with maleic anhydride), and 0.071 μgP/cm^2 for PE-g-MAe (PE-g-MA enriched in MA). Increasing polyolefins' polarity did not result in a significant increase in phosphate removal. Activated polyolefins with Al_2O_3 presented maximum amounts of phosphorus removal of 0.863 μgP/cm^2 for PE, 0.948 μgP/cm^2 for PE-g-MA, and 0.884 μgP/cm^2 for PE-g-MAe. As expected, addition of Al_2O_3 considerably increased phosphate removal. In kinetic experiments carried out with polyolefins activated with Al_2O_3 during 3 months a very high percentage of phosphorus removal was obtained for (> 90 %) as well as a very low remaining phosphorus concentration in solution (< 10 μgP/L).
As a conclusion, polyolefins activated with Al_2O_3 effectively removed phosphorous from aqueous solutions with low concentrations which indicate that this material might be used for in-situ remediation of eutrophic waters. The possibility to recover the material after use to recycle phosphate and the absence of precipitates' formation are two major advantages of this process.

Introduction

Phosphorus (P) is an essential nutrient for plant growth and has been intensively used as a fertilizer in agriculture. This practice contributed to the eutrophication of aquatic ecosystems (e.g. lakes, rivers and marshes), causing algal blooms which ultimately lead to oxygen depletion and generally poor water quality (Ribero et al., 2008). Re-dissolution of phosphate accumulated in the sediments, under certain environmental conditions (temperature, redox potential, pH, dissolved oxygen concentration, bacterial activity), might also be responsible for the occurrence of algae blooms especially when external nutrient sources are controlled (Martins et al., 2008).
P inactivation is a lake restoration technique. Its purpose is to lower the lake's P content by removal of P from the water column (P precipitation) and/or by retarding P release from lake sediments (P inactivation). Remediation solutions have been tested for a long time but with limited success. A literature review on materials used for P removal, classified in appropriate groups, is given in Table 1.

From all adsorbents shown in Table 1, activated alumina might be one of the most suitable materials to be used in phosphorus removal from natural waters with eutrophication problems. Activated alumina (aluminum oxide activated at 600 ºC) has a very high surface area (300 m^2/g) and is selective for phosphorus in the presence of nitrate and sulfate ions (Hano et al., 1997; Donnert and Salecker, 1999). The mechanism of phosphate removal by activated alumina is mainly ion exchange associated with chemical reaction, precipitation and formation of complexes (Narkis et al., 1981).

Materials and Methods

Materials

Polyolefins, polyethylene (PE), polyethylene grafted with maleic anhydride (PE-g-MA), and PE-g-MA enriched in maleic anhydride were used as polymeric matrices to remove phosphorus from an aqueous solution. The maleic anhydride increases the polarity of the resulting polymeric matrix thus enhancing the contact between aqueous and solid phases. In addition, the polymeric matrices were loaded with Al_2O_3 (5.0 %) which was dispersed onto their surfaces. Polymeric plates (12 cm × 18 cm × 0.2 cm) were made in a hot plat press (Moore) at a temperature of 453.15 K and using a final pressure of 30 ton. They were divided into sections with variable dimensions. Al_2O_3, provided by Sigma Aldrich in pellets of 3 mm, was crushed and sieved to an effective size in the range of 500 µm to 1 mm.

Stock phosphorus solution

A stock phosphorus solution with a concentration of 40 mg/L was prepared by dissolving 175.75 mg KH_2PO_4 in 1 L of pure water and used to prepare solutions with lower concentrations. Phosphate concentration was determined spectrophotometrically at a wavelength of 882 nm using the Ascorbic Acid method (4500 - PE, in Standard Methods, 17th Edition 1989).

Kinetic experiments

Kinetic experiments were carried out to determine phosphate removal from a solution with an initial P concentration of 100 µg/L. Firstly, experiments were performed in glass beakers where 2.5 g of each material present as granules, PE (3 mm), PE-g-MAe (1 - 3 mm), and Al_2O_3 (0.5 – 1 mm), was placed in contact with 100 mL of a 100 µg/L P solution at 100 rpm and 22 ºC during 7 d. Secondly, polymeric plates with similar areas, 10.5 cm^2 (4.0 cm × 1.0 cm × 0.2 cm), with and without prior activation with Al_2O_3, were placed in glass beakers containing 100 mL of a 100 µg/L P solution at room temperature for 16 d and 90 d without agitation. Samples were taken regularly and the phosphorus content was measured.

Influence of pH on P adsorption onto polymeric plates

Kinetic experiments with polymeric plates activated with Al_2O_3 were carried out as described preciously at pH values of 2, 4, 5, 6, 7, 8 and 9, during 7 d, at 100 rpm and 22ºC. The pH was adjusted by addition of either 2 M NaOH or 2 M HCl.

Determination of phosphorus uptake

The amount of phosphate removed, *q* (µg/cm^2), onto polymeric matrix was calculated by the following equation:

$$q = \frac{(C_i - C_e)}{A} \cdot V \qquad [1]$$

where C_i and C_e are initial and equilibrium phosphorus concentrations in solution (µg/L), V is the solution volume (L), and A is the area of polymeric matrix (cm^2).

Results and Discussion

Kinetic experiments

Figure 1 depicts the concentration of phosphorus in solution obtained in assays carried out with granular polyolefins and Al_2O_3. Phosphorus removal was higher and faster in the presence of Al_2O_3. A decrease of 83 % in phosphorus concentration was observed for Al_2O_3 during the first day as compared to 40 % for PE and 43 % for PE-g-MA.

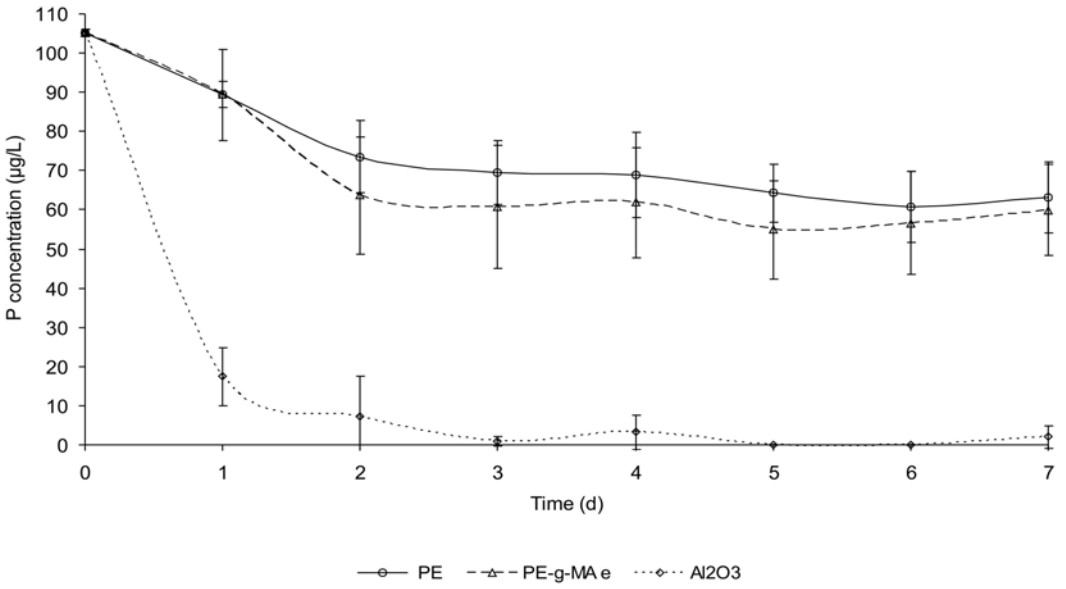

Figure 1 – Phosphorus in solution obtained in assays carried out with granular polyolefins and Al_2O_3.

Figure 2 depicts the concentration of phosphorus in solution obtained in assays carried out with polyolefin plates with and without previous activation with Al_2O_3. A limited affinity between polyolefin plates and phosphorus was observed after 16 d, as indicated by the low amount of P removed, respectively 0.042 µgP/cm^2 for PE, 0.049 µgP/cm^2 for PE-g-MA, and 0.071 µgP/cm^2 for PE-g-MAe. The amount of phosphorus removal was limited by the surface area available. Higher phosphorus removal were obtained for polyolefins activated with Al_2O_3, respectively 0.46 µgP/cm^2 for PE+5% Al_2O_3, 0.56 µgP/cm^2 for PE-g-MA+5% Al_2O_3, and 0.79 µgP/cm^2 for PE-g-MAe+5% Al_2O_3. The highest phosphorus removal was obtained in the case of PE-g-MAe. This result seems to indicate that polymers with higher polarities remove more phosphorus. During the first 19 h of contact phosphorus concentration decreased from 97 µg/L to 72

µg/L and after 16 d a final concentration of 14 µg/L was achieved for PE-g-MAe+5% Al_2O_3. A very high percentage of phosphorus removal was obtained as well as a low remaining phosphorus concentration in solution. By the end of the experiment the equilibrium phosphorus concentration was not yet reached. A new experiment was carried out for 90 d with the most promising materials, as depicted in Figure 3.

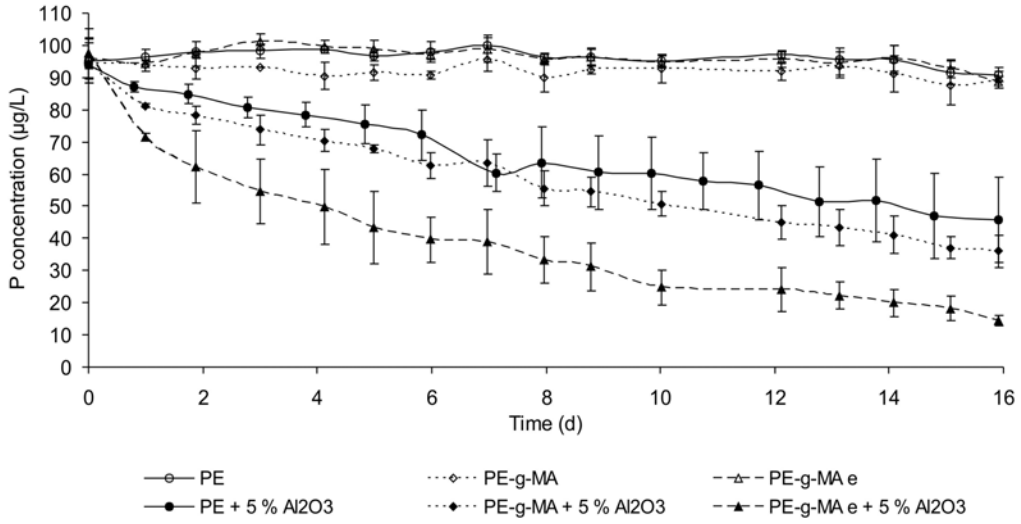

Figure 2 – Phosphorus in solution obtained in assays carried out with polyolefin plates with and without Al_2O_3.

The maximum amount of phosphorus removed by polyolefin plates activated with Al_2O_3 was 0.86 µgP/cm^2 for PE, 0.95 µgP/cm^2 for PE-g-MA, and 0.88 µgP/cm^2 for PE-g-MAe. Although the initially kinetics of phosphorus removal is faster for PE-g-MAe, phosphorus concentration remaining in solution after 90 d was below 10 µg/L in all cases, as depicted in Figure 3.

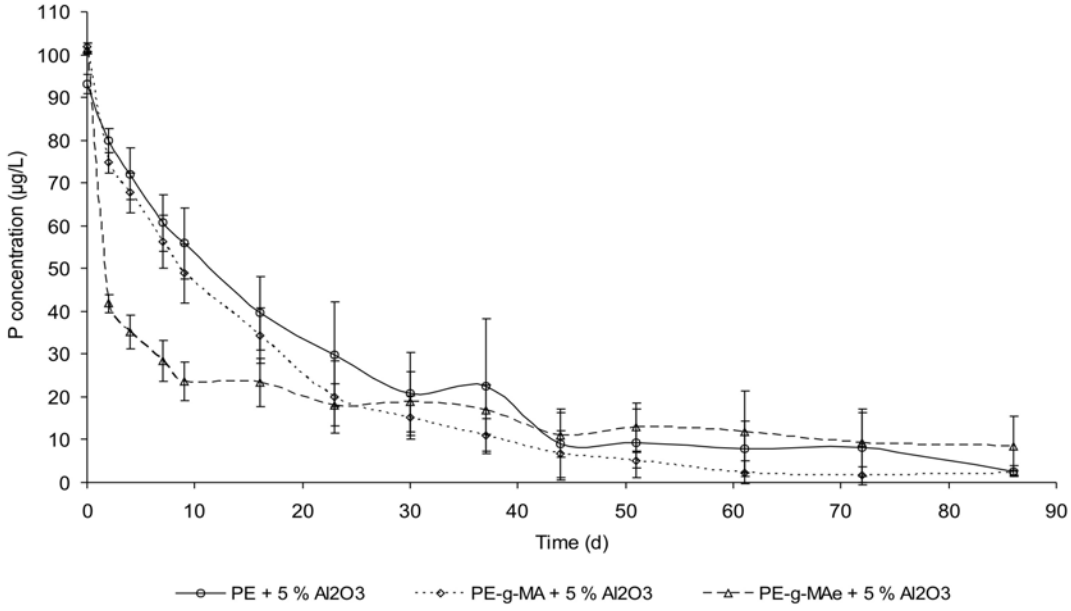

Figure 3 – Phosphorus in solution obtained in assays carried out with polyolefin plates activated with Al_2O_3.

The amount of phosphorus removed by polyolefin plates activated with Al_2O_3 at different pH values is shown in Figure 4. The percentage of phosphorus removal of activated PE and PE-g-MA decreases with an increase of pH while PE-g-MAe presents a stable maximum removal between pH 5 and pH 8 seems to be the most promising one. Increasing PE's polarity shifts maximum phosphorus removal from acidic to neutral/basic pH values. These results seem to indicate that the interaction between pH and polarity is a key factor in phosphorus removal and that the mechanism responsible for phosphorus removal might be ion exchange.

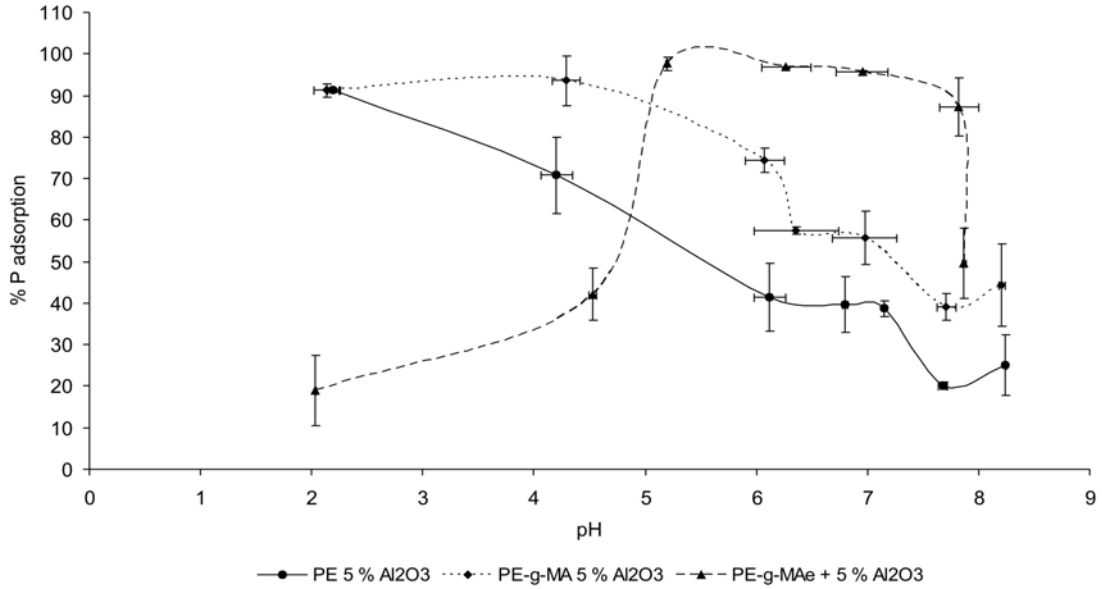

Figure 4 – Percentage of phosphorus removal as a function of pH in assays carried out with polyolefin plates activated with Al_2O_3.

Conclusions

The present study indicates that polyolefins activated with Al_2O_3 remove efficiently phosphorus from low solutions with low concentrations. The maximum removal capacities obtained were 0.86 μgP/cm^2 for PE, 0.95 μgP/cm^2 for PE-g-MA, and 0.88 μgP/cm^2 for PE-g-MAe. Furthermore, it was found that phosphorus removal efficiency depended on pH. The best results were obtained for PE-g-MA enriched in maleic anhydride that presented a maximum phosphorus removal in a pH interval between 5 and 8.

Topic: Integration of life sciences & engineering

Abstract

The pollution caused by heavy metals is one the major environmental problems that is imperative to be solved. New technologies, easy to implement and to adapt to any system, deserve special attention and are the focus of this presentation. This paper aims to investigate the biosorption behaviour of a biofilm of *E. coli* supported on kaolin clay for the treatment of cadmium, iron, nickel and chromium aqueous solutions. The effect of metals initial concentrations were studied and the relationship between pH and removal efficiency were analysed. Adsorption characteristics of a biosorbent can be depicted by an adsorption isotherm. Langmuir, Redlich-Peterson and Sips are commonly used for the description of adsorption data and were applied to the experimental results described by this report. The presence of functional groups in the suspended biomass that may have a role in biosorption process was confirmed by FTIR. It was demonstrated that a biofilm of *E. coli* supported on kaolin is able to remove Cr (VI), Cd (II), Ni (II) and Fe (III) from aqueous solutions. The isotherms were fitted and the best fit for chromium and nickel was obtained with the Redlich-Peterson model isotherm and for cadmium the best fit was the obtained with the Sips model. In terms of removal percentage, the results showed 100% of removal for iron for the whole range of concentrations tested. For cadmium, the removal percentage remains around 70% for all the initial concentrations tested (between 67.1% and 78.9%) and is higher than the obtained for nickel and chromium. The analyses by FTIR showed that functional groups on the biomass, such as hydroxyl, carboxyl and phosphate groups, may be the main binding sites for biosorption of the studied heavy metals by *E. coli*. Finally, the metal affinity to the biofilm was found to follow the sequence Fe > Cd > Ni > Cr and the preference of a sorbent for a metal may be explained on the basis of electronegativity of the metal ions and on the basis of the cation/anion state.

Materials and Methods

The bacterium *Escherichia coli* was obtained from the Spanish Type Culture Collection of the University of Valência. Heavy metals solutions were prepared by diluting $K_2Cr_2O_7$, $FeCl_3.(6H_2O)$, $CdSO_4.(8/3H_2O)$ and $NiCl_2(6H_2O)$, in distillated water. Atomic absorption spectrometric standards were prepared from 1000 mg/l metal solutions. The kaolin was obtained from Minas de Barqueiros, S.A. (Apúlia, Portugal).

A medium with 5 g/l of beef extract, 10 g/l of peptone and 5 g/l of NaCl (pH 7.2) was used for the microorganism growth. The medium was sterilized at 121 ºC for 20 min, cooled to room temperature, inoculated with bacteria and kept at 37 ºC for 24 h with

* Corresponding author. Tel + 351-253604400. E-mail:cquintelas@deb.uminho.pt

moderate stirring in a incubator. Then, batch experiments were conducted using 1 g of kaolin clay with 15 ml of *E. coli* culture media and 150 mL of the different metal solutions (10, 25, 50, 70, 80, 100 mg/l) in 250 ml Erlenmeyer flasks. All experimental work was conducted in duplicate. The Erlenmeyer flasks were kept at 37 ºC, with moderate stirring for about 10 days. Samples of 1 ml were taken, centrifuged and analyzed for metals using atomic absorption spectrophotometry, Varian Spectra AA-400.

Infrared spectra of the unloaded biomass and heavy metal loaded biomass, both in suspension, were obtained using a Fourier transform infrared spectrometer (FTIR BOMEM MB 104). For the FTIR study, biomass is centrifuged and dried, followed by weighting. Then 10 mg of finely ground biomass was encapsulated in 100 mg of KBr in order to prepare translucent sample disks. Elemental chemical analyses (Si, Al, Na, Cr, Cd, Fe and Ni) were performed by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) using a Philips ICP PU 7000 Spectrometer on samples.

Results and Discussion

The results obtained for the batch biosorption studies showed differences on the biosorption performance between the four metals studied (Table 1). Kaolin surface in water has a net negative surface charge (Turan *et al.*, 2007) and the bacteria have also a net negative charge (Tavares *et al.*, 2006). These negative surfaces obviously favour the biosorption of cations. In addition to the valence state, the electronegativity, atomic weight and ionic radius are also characteristics that influence the biosorption capacity.

Table 1- Uptake values (mg/g) and removal percentage values for Cr (VI), Cd (II), Fe (III) and Ni (II), obtained for the highest initial concentration of metal (37 ºC, 150 rpm), for the biofilm of *Escherichia coli* supported on kaolin

Cr (VI)			**Cd (II)**		
C_0 (mg/l)	**Uptake (mg/g)**	**Rp (%)**	**C_0 (mg/l)**	**Uptake (mg/g)**	**Rp (%)**
116	4,6	26,2	97	10,3	71,3
Fe (III)			**Ni (II)**		
C_0 (mg/l)	**Uptake (mg/g)**	**Rp (%)**	**C_0 (mg/l)**	**Uptake (mg/g)**	**Rp (%)**
110	16,5	100	101	6,9	45,3

The sequence in terms of uptake values by the *E. coli* biofilm supported on kaolin was Fe > Cd > Ni > Cr. The worst biosorption behaviour obtained for chromium is justified by the anionic state. Comparing the results obtained for the cationic metals, better results were obtained for iron and can be justified with the higher electronegativity and reduced ionic radius which promote the penetration into the polymeric net of the biofilm. Considering the ions Cd and Ni, this last one has higher electronegativity, lower atomic weight and ionic radius and these characteristics allows good qualities for metal entrapment. However, better results were obtained for cadmium. A possible explanation for these unexpected results might be the xenobiotic effect of the metal, more accentuated in the nickel case, on the biofilm. In a system biofilm-kaolin both materials contribute to the biosorption performance and if the biofilm is affect by the toxic nickel ion, the biosorption performance is affect too.

It is possible to characterize biosorbents under various operational conditions through the modelling of equilibrium data and this point is essential for future industrial applications. Adsorption isotherms were experimentally determined for the biosorbent used (biofilm + kaolin), and results are shown in Figure 1. Three different models - Langmuir, Sips and Redlich-Peterson- were fitted to the experimental data and constants calculated for the best fit are presented in Table 2. For iron and for the range of initial concentrations tested, the whole metal was immediately and totally biosorbed so the concentration at equilibrium was always zero and consequently it is not possible to represent Ce (mg/l) vs Qe (mg/g). The best fit for chromium and for nickel was obtained with the Redlich-Peterson model isotherm and for cadmium the best fit was reached with the Sips model.

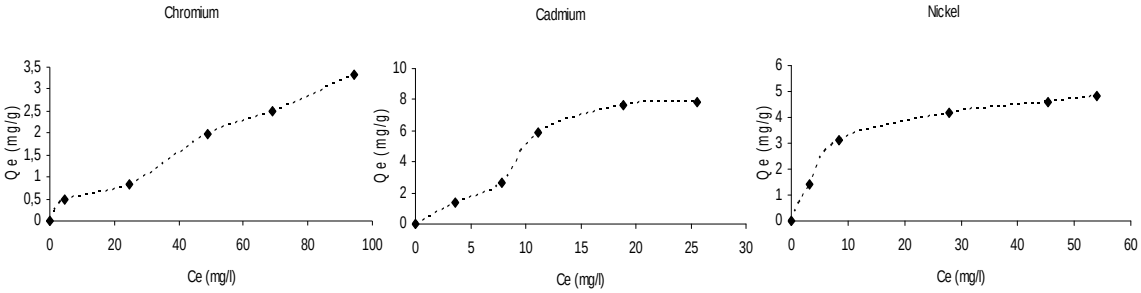

Figure 1- Adsorption isotherms for chromium, cadmium and nickel, at 37 ºC, using a biofilm of *Escherichia coli* supported on Kaolin.

Table 2- Adsorption isotherm constants for the isotherm best fit models, for Cr(VI), Cd(II) and Ni(II) onto a biofilm supported on Kaolin

Chromium				
Best fit model	K_R	a_R	β	R^2
Redlich-Peterson	0,615	8,629	0,143	0,984
Cadmium				
Best fit model	K_s	a_s	b_s	R^2
Sips	0,019	0,002	2,750	0,977
Nickel				
Best fit model	K_R	a_R	β	R^2
Redlich-Peterson	0,733	0,136	1	0,994

The FTIR spectra of unloaded and metal loaded *Escherichia coli* biomass in the range of 500–4000 cm^{-1} were taken to confirm the presence of functional groups that may be responsible for the biosorption process and are presented in Figure 2. As it may be seen, unloaded biomass displays a number of absorption peaks, reflecting the complex nature of the biomass. In the unloaded biomass spectrum, a peak at 3500–3200 cm^{-1} region is due to the stretching of the N–H bond of amino groups and indicative of

bonded hydroxyl group [40]. A change in peak position in the spectrum of the chromium and iron- loaded samples indicates the binding of chromium and iron with amino and hydroxyl groups. The absorption peaks at 2900–3000 cm^{-1} are ascribed to the asymmetric stretching of γC–H bond of the $–CH_2$ groups combined with that of the CH_3 groups [41]. The nickel and cadmium-loaded samples present slight changes in this region. In the unloaded spectrum, the γC=O of amide I and γNH/γC=O combination of the amide II bond were present at 1650 and 1544 cm^{-1}, respectively, indicating the presence of carboxyl groups. Interestingly, the 1544 cm^{-1} peak increased with the presence of chromium and iron suggesting an interaction of Cr and Fe with carboxyl groups. The peaks in the range 1300-1067 cm^{-1} are attributable to the presence of carboxyl and phosphate groups [42] and at 861 cm^{-1}, to the presence of aromatic –CH stretching peak [43]. Studies developed by Pradhan *et al.* [37] and Volesky (2007) [44] conclude that the main functional groups responsible for a biosorption process are the hydroxyl, carbonyl, carboxyl, sulfonate, amide, imidazole, phosphonate and phosphodiester groups, some of them present on the *Escherichia coli* biomass.

Topic: Suitable Integration of life sciences & engineering

Abstract

The need of treating textile wastewaters is nowadays well known, not only concerning primary and secondary treatments for organic matter and suspended solids removal, but also a tertiary treatment, mostly for residual colour removal.

Considerable work has been carried out on the removal of colour from textile wastes through chemical coagulation, chemical oxidation and biological techniques and by adsorption. Adsorption appears to offer the best prospects over all the other treatment techniques.

Activated carbon is one of the most widely used adsorbents in wastewater treatment. However, this treatment needs a high investment and leads to high operation costs, due to the high price of the activated carbon and to the high wastewater flow rate always involved, which can be greatly increased when there are no regeneration units nearby, as in the case of Portugal. This work intends to explore the adsorption capacity of cork (*Quercus suber L.)* granules to remove dye (Rouge Maxilon), from contaminated waters. The cork adsorption capacity has been studied for other pollutants (Domingues *et al*. 2007).

Adsorption batch assays with dye, using granulated cork with several different sizes, several pH values and different temperatures, were performed, either to determine the equilibrium time or the efficiency of the removal.

The results obtained have demonstrated that the cork is a cheap, efficient natural removing agent for Red Maxilon that may be explored in future to act as a treatment of wastewaters in textile industry.

1 Introduction

Among the different pollutants of aquatic ecosystems, dyes are a large and important group of industrial group in industrial chemicals. Most of this quantity is used in the textile industry and the dyes in use include many different compounds and their environment behaviour is largely unknown. Most dyes and pigments are considered either inert or non-toxic, although some are not totally innocuous. Interest in the environmental behaviour of dyes is prompted primarily by concern over their possible toxicity.

Concern as increased about the long-term toxic effects of water containing these dissolving pollutants. The wastewaters discharged from dyeing processes are highly colored, hot and alkaline, containing high amounts of dissolved solids (Rajeshwarisivaraj et al., 2001). Textiles wastewaters are significantly less biodegradable than many other carbonaceous wastes because the structures of the dye residues are designed to resist environmental conditions. There is a wide range in pH, making conventional biological and chemical treatment processes troublesome. The disposal of colored wastes such as dyes and pigments into receiving water damages the environment as they are toxic to aquatic life. In many cases,

* Corresponding author. Tel + 351-228340500. E-mail:vfd@isep.ipp.pt

the treatment of textile wastewaters takes places at municipal wastewater treatment plants using the activated sludge process.

Sorption is considered to be the primary removal mechanism for most dyes (Basibuyuk and Forster, 2003). A wide range of carbons exist for the possible use as adsorbents. A large number of activated carbons have been prepared from different raw materials, as coconut shells, rice husks, nut shells, peat moss and peat. Each has its own applications and limitations. Commercially available activated carbon is expensive. Taking this in account it is better to find out low-cost adsorbents to be used in this field.

Cork has already been studied to solve environmental issues. Chubar et al (Chubar et al., 2003) used cork biomass as sorbent for copper, zinc and nickel. Carvalho et al (Carvalho et al., 2003) produced activated carbon from cork waste to adsorb gas components. Cork residues has been used to adsorb pesticides from water (Domingues et al., 2005; Domingues et al., 2007). Cork industry creates an enormous volume of waste (specially particles with very small dimensions). The chemical composition of cork is described as suberin, 39%; lignin 22%; polysaccharides 18%; extractives 15% and ash 1% (Pereira, 1988).

In this work, adsorption characteristics of red maxilon in various solutions conditions are investigated. All isotherms were obtained in pH controlled solutions. Some of the experimental isotherms are fitted by Langmuir model.

2 Materials and methods

Materials

Granulated cork from the same geographical area and therefore with similar composition, was supplied by Amorim & Irmãos, S.A., Portugal. The cork fractions with a particle diameter between 1-2 mm (1<d<2) and 3-4 mm (3<d<4) were separated and used. To remove exceeding powder, all the granulated material was washed with deionized water and dried at 105 ± 5ºC for 4 days.

The adsorbate used was the rouge maxilon kindly given by CIBA. All the solutions were prepared with deionised water. A solution of hydrochloric acid and sodium hydroxide was use for pH adjust.

Batch adsorption study

For kinetic studies, a series of Erlenmeyer flasks of 100 mL capacity containing 50 mL of dye solution of known initial concentration was shaken in a rotary shaker (75 rpm) with 0.2 g of cork 1<d<2 or 3<d<4.. Light was excluded to prevent photodegradation. An Erlenmeyer flasks without adsorbent was study simultaneously in each experiment to verify a stability of the dye.

The equilibrium adsorption experiments were conducted to obtain sorption isotherms with a equilibrium time of 1 weak. The adsorption capacities of both granules of cork were determined using batch experiments at 40ºC and 10ºC with a Thermostatcabinet Lovibond. The adsorption study of these adsorbates was achieved by varying the weight of adsorbent. Additionally, flasks with red of maxilon and without cork were used as controls.

At the end of adsorption period, the solution went trough a metal sieve. The filtrate was analyzed on a spectrophotometrically (UV Visible Recording Spectrophotometer 260 – Shimadzu). The adsorption values of dye before and after adsorption were measured at is maximum wavelength (530 nm).

Calibrations curves are obtained with standards of red maxilon solutions in pH 4 and pH 9. The amounts of dye adsorbed were calculated by subtracting final solution concentrations

from the initial concentration of aqueous solution. Blank solutions were used for each series of experiments.

$$q = (C_0 - C_e)\frac{V}{m} \qquad (1)$$

Where q is the red maxilon amount adsorbed per gram of cork, C0 and Ce is the initial and equilibrium concentration of dye in solution (mg/L), V is the volume of red maxilon (L) and m is the mass of adsorbent (g).

3 Results and discussion

Preliminary experiments showed that the effect of the time on the amount of dye in Erlenmeyer flaks without cork was neglible.

At equilibrium the adsorption process is considered to be a dynamic state in which the rate of the adsorption process equals that the desorption process. The studies to determine equilibrium time are represented in Figure 1.

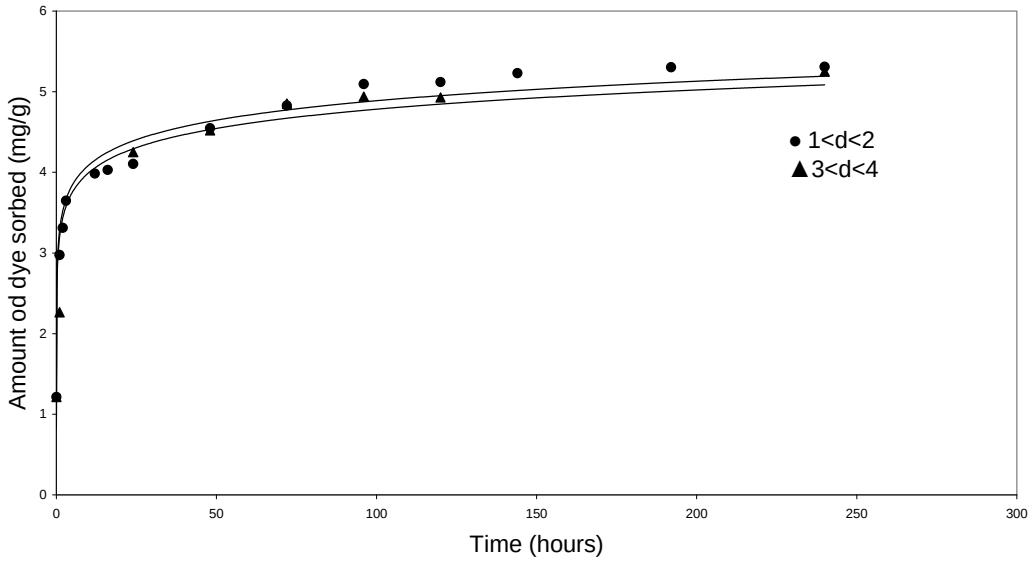

Figure 1. Equilibrium time determination of red maxilon in cork 1<d<2 and cork 3<d<4.

The equilibrium was reached after six days for both sorbents, denoting a slightly faster equilibrium for cork. An incubation period of a weak was adopted for all sorbents to ensure that equilibrium was reached. The sorption kinetics of cork correspond to the L type in the classification proposed by Giles et al (Giles et al., 1960), which means that as the adsorption sites are being occupied, it becomes increasingly more difficult for adsorbate molecules to find vacant sites.

Adsorption equilibrium is governed by several factors such as the nature of adsorbate and adsorbent as well pH and temperature (Dogan et al., 2008).

A plot of red maxilon quantity on the adsorbent against the equilibrium concentration of red maxilon in the solution at a constant temperature is commonly referred as an isotherm. It can

be said that the adsorption isotherm is the equilibrium relationship between the concentration in the fluid phase and the concentration in the adsorbent particle at a given temperature.

The experiment isotherms of red maxilon in cork residues with granule diameter of 3-4 mm and 1-2 mm at 10ºC and 40ºC are shown in Fig 2 and Fig 3 respectively.

It is clearly seen from the experimental results that red maxilon was removed more effective by cork at pH 4 than pH 9.

Although the red maxilon adsorption isotherms reveal adsorption at pH 4 all are non-linear indicating the sorption occurred by a physical adsorption mechanism.

Langmuir model was used to analyze the adsorption behaviour and to determine the red maxilon adsorption capacity on cork with different sizes. For a single solute system, Langmuir isotherm may be expressed as

$$q = \frac{q_m K_L C_{eq}}{1 + K_L C_{eq}} \qquad (2)$$

where *qm* is *q* for a complete monolayer, *KL* is the Langmuir constant and *Ceq* is the concentration of red maxilon in equilibrium.

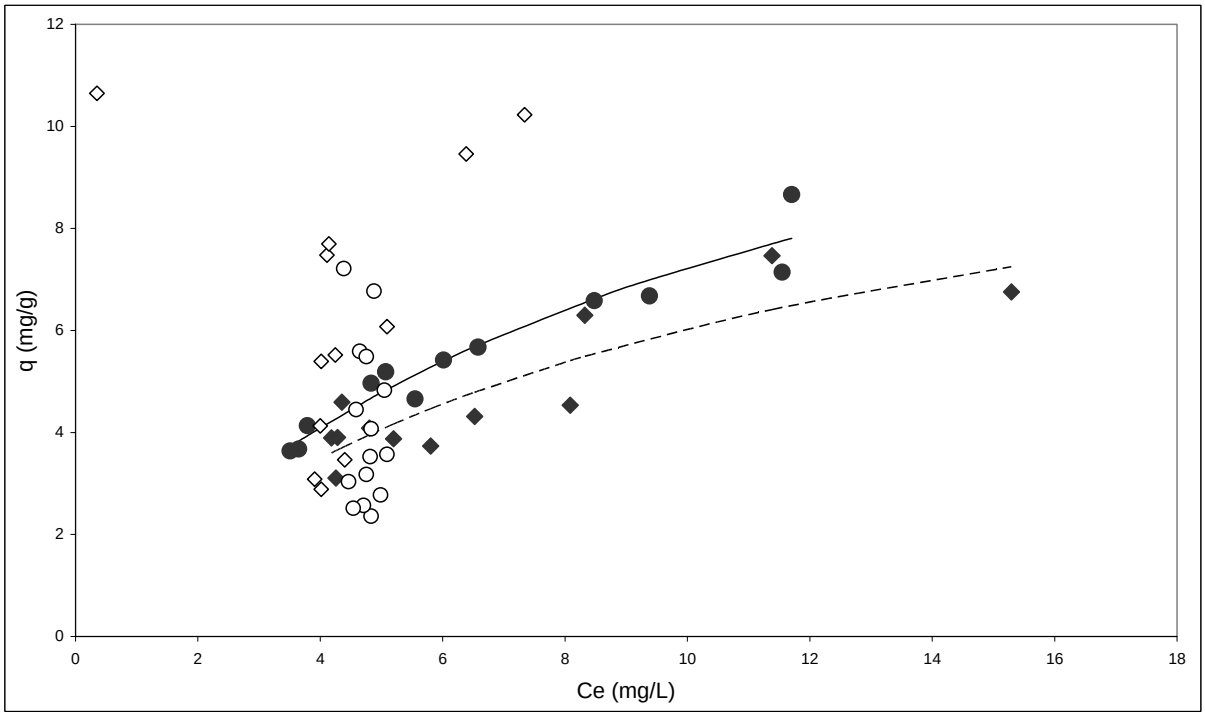

Figure 2. Experimental isotherm at 10ºC of red maxilon on cork with diameter 3-4 (♦) and 1-2 mm (●) at pH 4 fitted by Langmuir model and cork 3-4 (◊) and 1-2 mm (○) at pH 9.

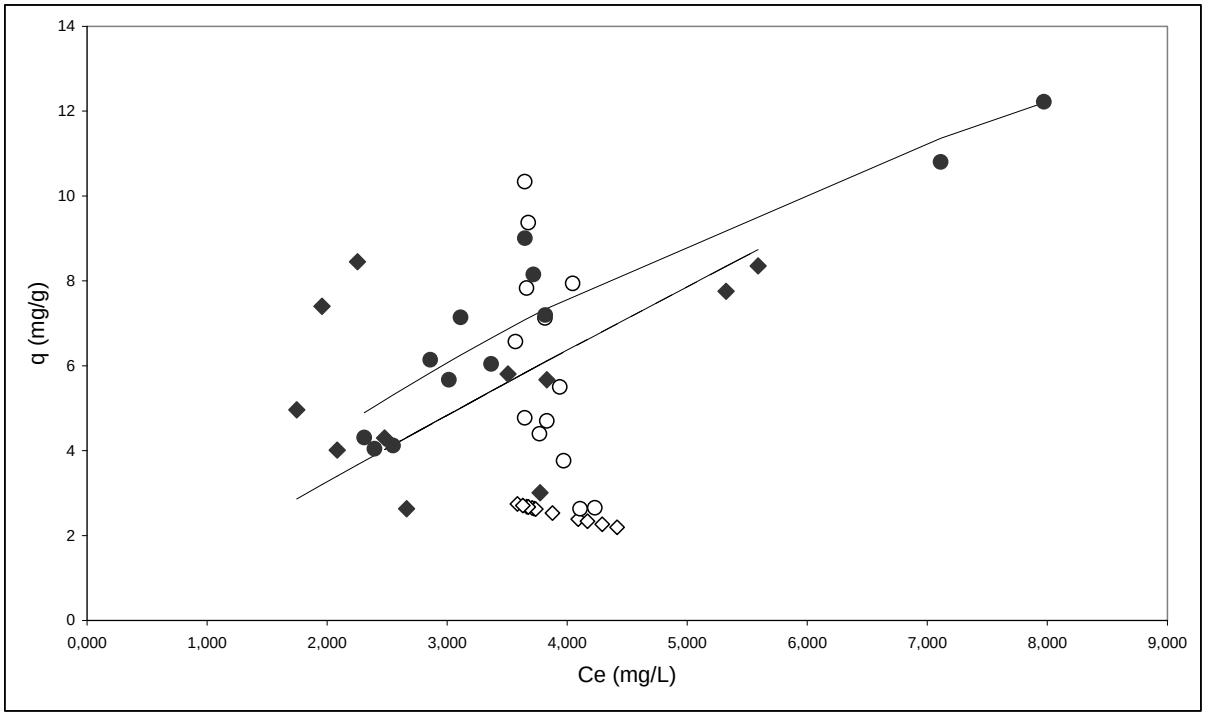

Figure 3. Experimental isotherm at 40ºC of red maxilon on cork with diameter 3-4 (♦) and 1-2 mm (●) at pH 4 fitted by Langmuir model and cork 3-4 (◊) and 1-2 mm (○) at pH 9.

The above equation (2) can be modified to give

$$\frac{1}{q} = \frac{1}{q_m} + \frac{1}{K_L q_m C_{eq}} \quad (3)$$

A plot of *1/q* against *1/Ceq* will give a straight line for the isotherm if the relationship can be applied. Consequently, the *qm* can be found from the intercept of the stright line. It is common to describe the fit of linear regression in term of R^2, which is the square of correlation coefficient. If the R^2=1, then the fit is perfect, but R^2 is always less than unity (Wibulswas, 2004).

Another possibility to achieve *qm* is to use the solver tool from Excel®, with minimization the differences between the *q* experimental and *q* with Langmuir equation.

In Table 1. are represented the *qm* achieved by minimization the differences and by linearization.

Table 1. Red maxilon adsorption capacity by means of Langmuir isotherm

Adsorbent	pH	Temperature (ºC)	Adsorption capacity by minimization of differences (mg/g)	Adsorption capacity by linearization (mg/g)	R^2
Cork 1-2 mm	4	10	14.75	15.53	0.956
Cork 3-4 mm	4		11.73	12.53	0.806
Cork 1-2 mm	9		Not fit	Not fit	
Cork 3-4 mm	9		Not fit	Not fit	
Cork 1-2 mm	4	40	31.20	91.75	0.991
Cork 3-4 mm	4		129,37	33.12	0.291
Cork 1-2 mm	9		Not fit	Not fit	
Cork 3-4 mm	9		Not fit	Not fit	

The *qm* data obtained by linearization and by minimization of the differences are consistent for pH 4, at 10ºC for cork 1-2 mm and cork 3-4 mm. Cork 1-2 with a *qm* higher than cork 3-4, that means the available surface are to adsorption is essential the external one.
The results show that adsorption increases with temperature, nevertheless cork 3-4 obtain a higher *qm* it does not fit so well than the other data (R^2=0.291).

4. Conclusions

The adsorption of red maxilon on cork was endothermic indicating that a higher temperature would be favourable for carrying out the removal of dye, which is especially adequate for textile water treatment.
However the binding of red maxilon to cork residues was poor at pH 9. Only the adsorption isotherm at pH 4 is fitted by Langmuir model. The cork particle 1<d<2 shows a higher adsorption than cork particle 3<d<4.
The results of present investigation show that cork particles, low cost material, have suitable adsorption capacity with regard to the removal of red maxilon from its aqueous solution. The cost and adsorption characteristics favour cork to be used as an effective adsorbent for removal the red maxilon from wastewater in Portugal.

Influence of airflow rate on soil remediation using Soil Vapour Extraction

Keywords: Soil Vapour Extraction, Airflow rate, Soil, Volatile Organic compounds
Topic: Integration of life sciences & engineering

Abstract

The release of contaminants into the soil matrix produces a negative impact on soil quality, creating, in some cases, situations of risk to public health. Halogenated volatile organic compounds and the group constituted by benzene, toluene, ethylbenzene and xylene are common compounds found in contaminated sites. To remediate these sites several techniques can be used: biological processes (such as bioremediation or phytoremediation), thermal processes (such as incineration or thermal desorption) and physico-chemical processes (such as chemical oxidation or soil vapour extraction).

Soil Vapour Extraction (SVE) is one of the most used technologies that can be applied to soils contaminated with volatile or semi-volatile organic compounds in the unsaturated zone. It applies vacuum to the soil matrix, creating an airflow that transports the contaminants to extraction wells. The air circulation through the soil matrix produces mass transfer into the gas phase, due to free pollutant volatilization, desorption from the soil and dissolution from the aqueous phase. Before reaching the atmosphere, these vapours are usually treated to guarantee legal limits and air quality. The success of a soil vapour extraction project depends on several parameters including contaminant characteristics such as vapour pressure and solubility, soil properties such as natural porosity, permeability, organic matter or water contents and operational conditions like temperature or airflow rate.

Experiments previously carried out with two soils contaminated with cyclohexane allowed concluding that for air flow rates lower than 1.5 $cm^3\ s^{-1}$, at Standard Temperature and Pressure (STP), the remediation efficiency did not depend on the volume of gas passed through the soil, because the equilibrium between the pollutant and the different phases present in the soil was reached and the diffusion effects were avoided.

A laboratorial installation was developed and used to simulate soil remediation using SVE. The remediation process was monitored and the contaminant quantification performed by gas chromatography using a flame ionisation detector.

In this work, six typical petroleum contaminants were studied, allowing the establishment of operational SVE conditions for the remediation of frequently found contaminated soils. The influence of airflow rate on soil vapour extractions was evaluated for sandy soils contaminated with benzene, toluene, ethylbenzene, xylene, trichloroethylene and perchloroethylene. The main objective was to select the best airflow rate to remediate soil contaminated with the studied contaminants and under the contaminations range experimented.

The results obtained for SVE performed with airflow rates within 0.50 and 5.3 $cm^3\ s^{-1}$ (STP) in sandy soils contaminated with the selected pollutants allowed concluding that: a) the

* Corresponding author. Tel + 351-228-340500. E-mail:jta@isep.ipp.pt

remediation efficiencies were always higher than 90%, b) depending on the contaminant, the airflow rates should be lower than 1.2 - 1.9 $cm^3 s^{-1}$ (STP).

1 Introduction

Human activities caused in the last decades severe impacts on the environment, namely in soil. Handling and abusive use of petroleum products and pesticides and industrial activity are simple examples of situation that lead to soil remediation. Increasing efforts have been done in order to invert and remediate these situations. For each specific case of soil contamination it is essential to choose the most appropriate remediation technology and to preview the remediation time. From the balance of these two items the most applicable technology may be selected. Soil vapour extraction (SVE) is one of the most used *in situ* technologies that can be applied to soils contaminated with volatile and semi-volatile compounds in the unsaturated zone. It is based on application of vacuum to the soil matrix creating airflow that transports the contaminant to extraction wells and consequently out of the soil for prior treatment before release to the environment.

The success of a soil vapor extraction action is influenced by contaminant characteristics, soil properties and operational conditions. These conditions enhance the volatilization of the contaminant becoming more available and easy to extract (Chai and Miura, 2004). High porosity and high permeability also benefits SVE, mainly, due to their positive impact on the airflow rate through the soil (Poulsen et al, 1999). On the opposite situation contaminants with high solubility and soils with high contents of water or natural organic matter create more difficult conditions for SVE (Albergaria et al, 2006; Yoon et al, 2002), due to dissolution in the soil water or to the adsorption on the organic matter, which decrease the mass transfer between the gas phase and the soil matrix. The induced gas flow towards the extraction wells causes the evaporation of the nonaqueous liquid phase, the volatilization of contaminants dissolved in the pore water and the desorption of chemicals from the porous material, increasing the mobility and availability of the contaminant, consequently increasing the remediation efficiency (Kaleris and Croisé, 1997). The air circulation into the soil matrix is not homogeneous, being influenced by soil heterogeneities. Due to this, the air flows through paths of lower resistance, avoiding regions of lower permeability. These regions will not be crossed by the airflow and consequently will be remediated only through diffusion. Furthermore, these untreated regions can act as sources of contamination to surrounded remediated soils and groundwater (Reddy and Adams, 2001) leading to higher remediation times, lower efficiencies and more expensive processes. The remediation time of soils using soil vapor extraction is inversely proportional to the air flow rate, but to take full advantages of that relation, equilibrium between the pollutants and the different phases present in soil matrix is necessary, and slow diffusion effects should not occur. Even modest non-equilibrium and slightly slow diffusion effects can strongly affect the efficiency and cost of the remediation process (Albergaria et al, 2006). This work reports the study of the influence of the airflow rate on soil vapour extraction remediation time and efficiency in a sandy soil contaminated with benzene, toluene, ethylbenzene, xylene, trichloroethylene and perchloroethylene.

2 Materials and Methods

2.1 Materials

Pro-analysis Benzene and Perchloroethylene were obtained from Riedl-de-Haën; Toluene, Xylene and Ethylbenzene were obtained from Merck; Trichloroethylene was obtained from Fluka.

2.2 Apparatus and chromatography

An Ai Cambridge GC95 gas chromatograph equipped with a flame ionisation detector was used to the quantification of the contaminants. A Chrompack Hayesep Q 80-100 mesh (3m x ¼" x 4 mm) packed column was used. The injector and the detector were set at 230 ºC and the oven worked isothermically at 200ºC. Flame gases were air, at 270 cm^3 min^{-1}, and hydrogen at 30 cm^3 min^{-1}. The carrier gas was nitrogen at 30 cm^3 min^{-1}. The direct calibration method was used.

2.3 Soil preparation and characterization

The sandy soil was collected in different places of a beach of Oporto region in Portugal, being stored in appropriate vessels. This sandy soil was mainly constituted by silica and shell debris, with negligible amounts of clay and natural organic matter. The preparation of soils involved: a) washing till clean water was obtained; b) drying, at room temperature during 5 days and then at 110ºC for 24 hours; c) sieving in a 2 mm sieve to obtain a granulometric fraction of the soil with uniform physical and chemical properties; and d) adding deionised water to induce the 2% water content in the soil. International standard methodologies were used for the characterization of the soil, including the determination of apparent density, particle density, porosity, pH, and the contents of water and natural organic matter (Albergaria, 2003).

2.4 Equilibrium isotherms

Equilibrium isotherms relating the contaminant concentration in the gas phase with the total amount of contaminant in soil were used to calculate remediation efficiencies, only through the experimental determination of contaminant concentration in the gas phase. The equilibrium isotherms were obtained performing experiments in stainless steel columns. These experiments involved: i) introduction of the soil in the column; ii) soil contamination (ranges within 6 up to 200 mg kg^{-1}); iii) equilibrium establishment (at 296K from 24 to 48 hours, depending on the contaminant); and iv) determination of the concentration of the contaminant in the gas phase (C_{gas}) through gas chromatographic analysis. The equilibrium was reached when C_{gas} in different levels of the column was similar (less than 5% deviation).

2.5 Soil vapour experiments

To perform the SVE experiments, columns were prepared in a similar way of the used to the equilibrium isotherms. The only difference was the contamination of the soil that ranged from 250 to 500 mg Kg^{-1}. After the equilibrium establishment a vacuum pump created an airflow rate (ranging from 0.50 cm^3 s^{-1} to 5.4 cm^3 s^{-1} at standard temperature and pressure (STP)) measured with a flow meter. The flow passed through the soil column and then to a sampling system where the contaminated emissions were monitored by gas chromatography. Before reaching the atmosphere and to avoid atmospheric contamination, the contaminant was adsorbed in activated carbon. The remediation process was considered finished when C_{gas} was below 1.0 mg L^{-1}. This time was considered the remediation time.

3. Results

3.1 Soil characteristics

Table 1 shows the results of the characterization of the sandy soil. The clay content was under the detection limit.

Table 1 – Characteristics of the sandy soil (particle size <2mm).

Apparent density ($g\ mL^{-1}$)	Particle density ($g\ mL^{-1}$)	Porosity (%)	pH	Water content (%)	Natural organic matter content (%)
1.3	2.5	49	8.8	2.0	<0.02

3.2 Equilibrium isotherms

Figure 1 shows the equilibrium isotherms obtained for all the contaminants and the respective trend lines. These equilibrium isotherms allowed the prevision of the amount of contaminant in the soil matrix only through the determination of contaminant concentration in the gas phase.

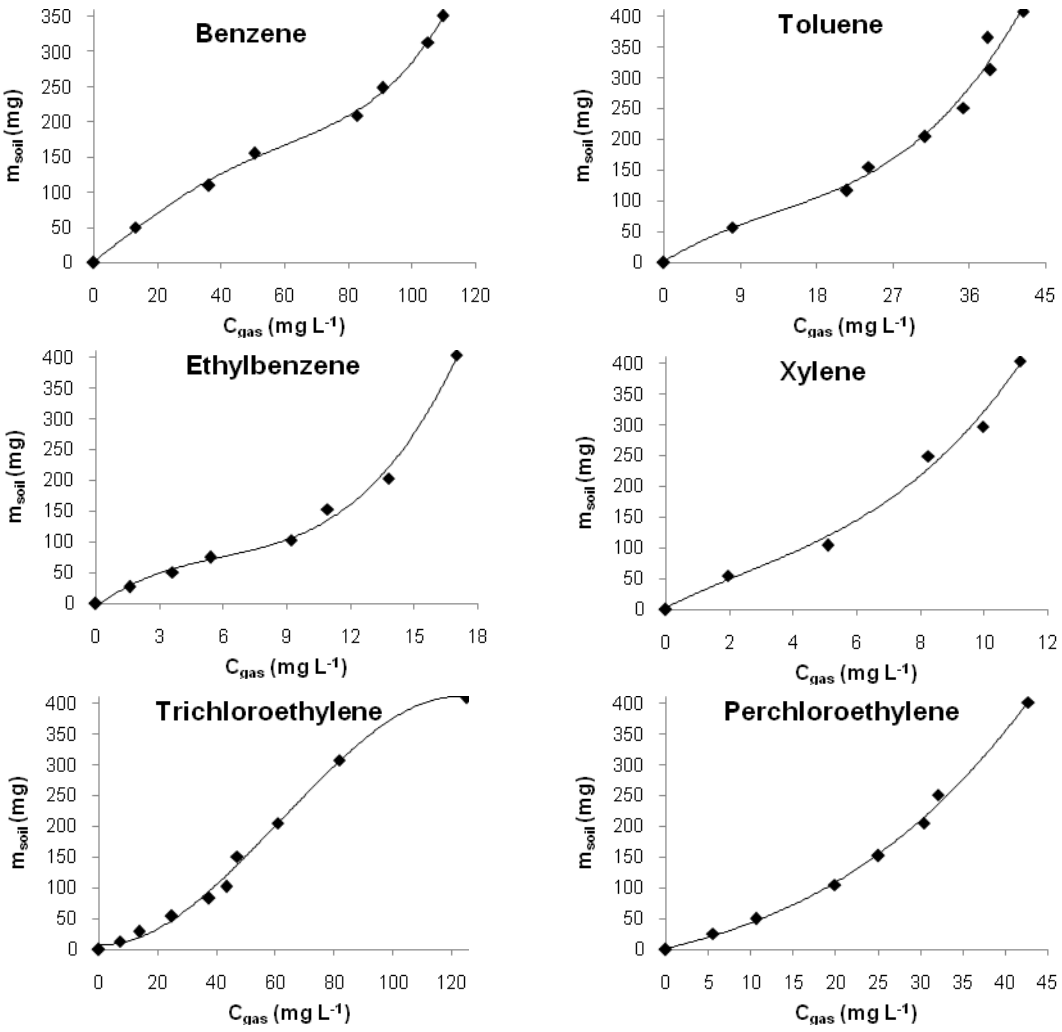

Figure 1 – Equilibrium isotherms for the different contaminants in a dry sandy soil.

3.3 Soil vapor extraction experiments

During the soil vapor extractions experiments the concentration of the contaminant in the emissions was monitored. When the concentration reached 1.0 mg L^{-1} the process was considered finished and the remediation time (tr) registered. The volume of air used (V) and the process efficiency (η) was then calculated, using equations 1 and 2 respectively, where Q is the airflow rate and t the time.

$$V = \int Q \, dt \qquad (1)$$

$$\eta = \frac{(m_{tot} - m_{rem})}{m_{tot}} \times 100 \qquad (2)$$

The results obtained in SVE experiments are presented in Figure 2. The results showed that for the prepared sandy soil the efficiencies were always above 90%, excepting SVE performed with PCE with the two highest airflow rates. These high values could be expected because the soil had undetectable amounts of organic matter, and consequently there were not enough strong bonding between the soil and the contaminants, leaving them more available to be extracted through SVE. Efficiencies increased for lower airflow rates indicating that equilibrium conditions favors contaminant extraction. The remediation time was inversely proportional to the airflow rate, showing that higher airflow rates allowed faster remediations.

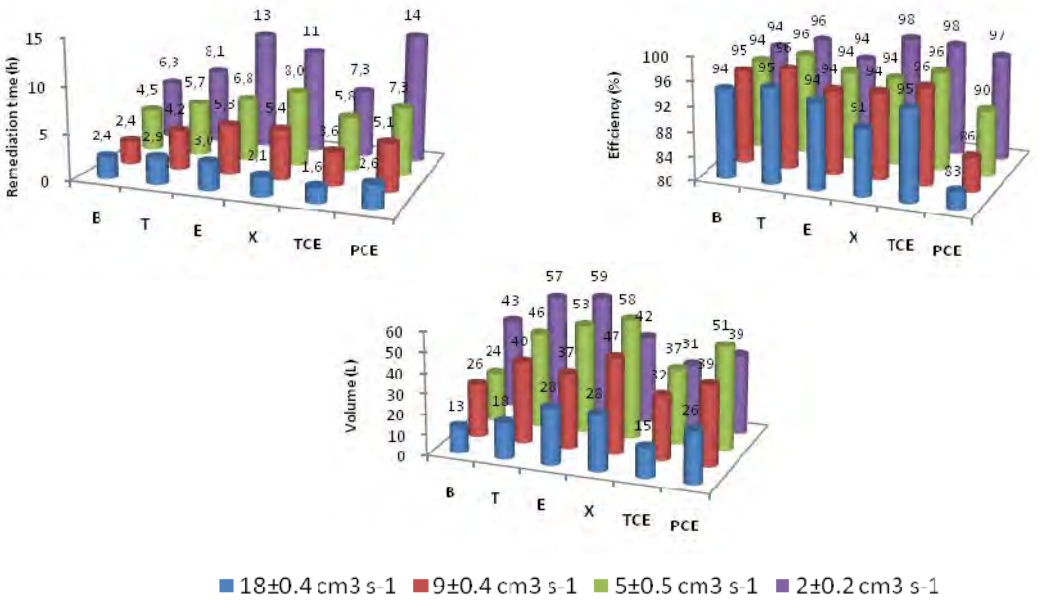

Figure 2 – Results obtained in the SVE experiments with sandy soils.

3.4 Selection of the most efficient airflow rate

All the results showed that the remediation time is inversely proportional to the air flow rate. Nevertheless, to take full advantage of airflow increase, equilibrium between the pollutants in the different phases must be reached and slow diffusion effects must be avoided. In these circumstances the remediation efficiency does not depend on the volume of air passed through the soil. To evaluate if those conditions were obeyed Figure 3 was constructed. It relates the remediation efficiency and the volume of gas passed through the column for the prepared soil. Two types of curves were observed: Trichloroethylene type (similar to xylene) where all curves are overlaid; and Toluene type (similar to benzene, ethylbenzene and perchloroethylene) where the curves tend to an equilibrium behavior.

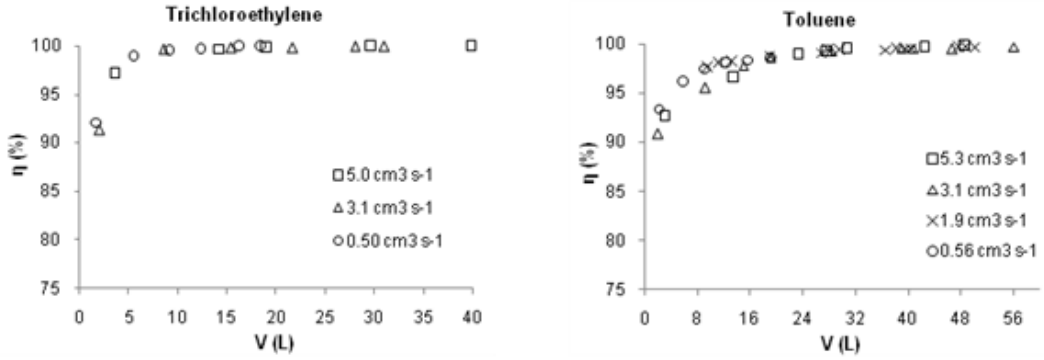

Figure 3 - Influence of airflow rate on the efficiency of SVE on the prepared soils (2% water content).

Attending to the curves obtained for all contaminants it was observed that for xylene and TCE the equilibrium was reached and slow diffusion effects were not observed for all the airflow rates used. For smaller volumes of air (smaller efficiencies) that behavior was reached for the other pollutants using flow rates smaller than 1.2 - 1.9 cm^3 s^{-1} (STP). Nevertheless, for higher efficiencies, flow rates of 5.3 cm^3 s-1 (STP) guarantee equilibrium and negligible diffusion effects.

4. Conclusions

The results obtained for SVE performed with airflow rates within 0.50 and 5.3 cm^3 s^{-1} (STP) in sandy soils contaminated with benzene, toluene, ethylbenzene, xylene, trichloroethylene and perchloroethylene allowed concluding that:

a) The remediation efficiencies were always higher than 90%;
b) For xylene and TCE the equilibrium was reached and slow diffusion effects were not observed for all the airflow rates used. For smaller volumes of air (smaller efficiencies) that behavior was reached for the other pollutants using flow rates smaller than 1.2 - 1.9 cm^3 s^{-1} (STP).

Abstract

Aqueous Two-Phase Systems (ATPSs) are biphasic systems composed mainly by water. ATPSs are obtained upon mixing of two aqueous solutions of certain polymers or a polymer and a salt (above certain critical conditions, e.g. concentration, temperature). These systems are commonly indicated for the extraction of biomolecules. In this work, the partition coefficients for a series of five dinitrophenylated amino-acids (ranging from glycine to amino-caprylic acid) were determined experimentally in five different polymer-salt ATPSs (polymers: PEG or Ucon; salts: Na_2SO_4, Li_2SO_4 or $(NH_4)_2SO_4$) at 23ºC. Values of the free energy of transfer of a methylene group, $\Delta G(CH_2)$, for the five ATPSs were obtained from the partition coefficients and compared with $\Delta G(CH_2)$ previously obtained for PEG-Na_2SO_4 (Rodríguez et al., 2007). Ucon-salt ATPSs presented higher values of $\Delta G(CH_2)$ than the corresponding PEG-salt systems, witch indicates that the Ucon-rich phase is more hydrophobic than the PEG-rich phase.

1 Introduction

Aqueous Two-Phase Systems (ATPSs) are biphasic systems composed mainly by water. ATPSs are obtained upon mixing of two aqueous solutions of certain polymers or a polymer and a salt (above certain critical conditions, e.g. concentration, temperature). These systems are regarded as a powerful extraction technique for biotechnology because each phase is predominantly composed of water (> 80%) and provide a gentle environment for the partitioning of sensitive biomaterials. For over 40 years ATPSs have been used for the purification and recovery of biological solutes such as proteins, amino acids, lipids, nucleic acids, viruses, plant and animal cells, etc. In the last 10 years ATPSs formed by thermo-separating polymers have been successfully used for the separation and purification of different types of biomolecules with considerable advantages in the recycling of the polymers (Pereira et al. 2003). Thermo-separating polymers, such as Ucon, are polymers whose solubility in water changes drastically with temperature and thus, can be easily recovered from the aqueous solution (and re-used).

Although the potential of ATPSs is well known, the wide use of this technology is partially limited by the lack of a clear comprehension of the factors and mechanisms that govern the distribution of solutes in ATPSs. Therefore, all attempts to obtain more information that allows understanding and predicting the behaviour of a solute are extremely important.

Among the studied solvent properties of ATPSs, the free energy of transfer of a methylene group between the coexisting phases, $\Delta G(CH_2)$, has been shown (Zaslavsky, 1995; Willauer et al., 2002) to be useful for the characterization of ATPSs. $\Delta G(CH_2)$ represents the affinities of the phases for a CH_2 group and is considered as a measure of the relative hydrophobicity of the phases. Hydrophobic interactions are critical for protein stability and thus, may play an important role in the partitioning of proteins in ATPSs.

In this work, $\Delta G(CH_2)$ for five different polymer-salt ATPSs are obtained from the experimental partition coefficients (K) of a series of dinitrophenylated amino-acids (DNP-amino-acids) at 23 ºC.

2 Experimental

Preparation of ATPSs: Biphasic systems were prepared at 23 ºC mixing suitable amounts of water and stock solutions of the polymers (PEG or Ucon) and the salts (Na_2SO_4, Li_2SO_4 or $(NH_4)_2SO_4$) in eppendorf tubes. The total weight of all systems was approximately 1.2 g.

Partition coefficients: The partition coefficients of the five DNP-amino-acids (*N*-(2,4-dinitrophenyl)glycine, *N*-(2,4-dinitrophenyl)-L-alanine, *N*-(2,4-dinitrophenyl)-DL-*n*-valine, *N*-(2,4-dinitrophenyl)-DL-*n*-leucine and *N*-(2,4-dinitrophenyl)-DL-α-amino-*n*-caprylic acid) were obtained adding different amounts of a given DNP-amino-acid stock solution (from 0 to 100 mg) to six replicates of the ATPSs with the same feed composition (table 1). The corresponding amount of water (ranging from 100 to 0 mg) was also added to keep all compositions constant except the solutes. The components were vortex mixed for 2 minutes and then centrifuged at 10^4 r.p.m. for 15 minutes to achieve phase separation. Samples of each phase were withdrawn, conveniently diluted, and their absorbance at 362 nm was measured. Partition coefficients were calculated as the slope of the straight line obtained when comparing the concentration (mg/mL) in the polymer-rich phase against that in the salt-rich phase, corrected with the corresponding dilution factor (DF):

$$K = \frac{Abs(polymer) \times DF_{polymer}}{Abs(salt) \times DF_{salt}} \quad (1)$$

Table 1: Tie-line feed compositions for partitioning experiments, in mass fraction

System	Salt	Polymer
PEG-Na_2SO_4	0.0727	0.1186
PEG-Li_2SO_4	0.1000	0.1400
PEG-$(NH_4)_2SO_4$	0.1100	0.1250
Ucon-Na_2SO_4	0.0413	0.1676
Ucon-Li_2SO_4	0.0570	0.1200
Ucon-$(NH_4)_2SO_4$	0.0650	0.1260

3 Results and Conclusions

The phase diagrams of the biphasic systems used in this work were previously obtained experimentally at 23ºC: PEG- Na_2SO_4 (Rodríguez et al., 2007), PEG-Li_2SO_4, Ucon-Na_2SO_4, Ucon-Li_2SO_4 (Silvério et al., 2008) and Ucon-$(NH_4)_2SO_4$ (Pereira et al., 2004). The phase diagram for the system PEG-$(NH_4)_2SO_4$ was obtained from the literature (Zaslavsky, 1995).

The logarithms of the partition coefficients (ln *K*) as a function of the average number of equivalent methylene groups, $n(CH_2)$, in the aliphatic side-chain of the homologous DNP-amino-acids are shown in figure 1.

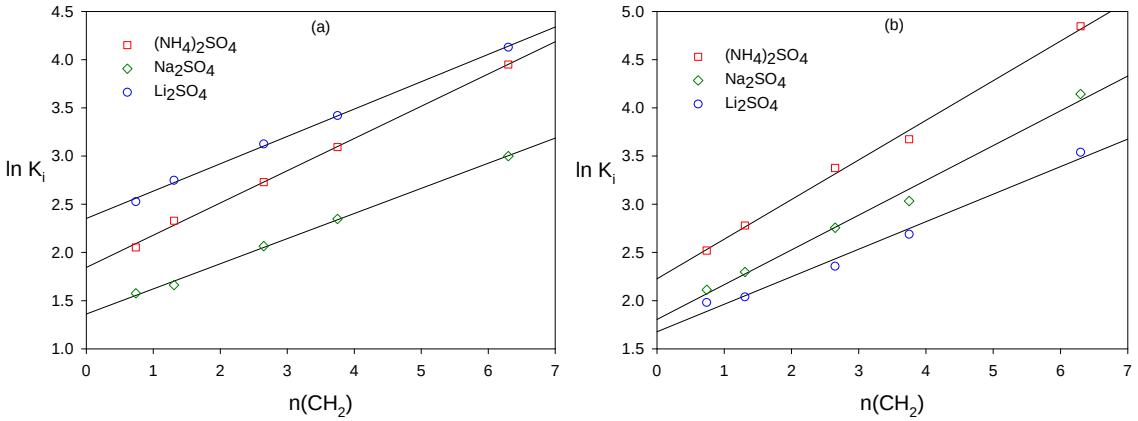

Figure 1: Logarithm of partition coefficients for a series of DNP-amino-acids in (a) PEG-salt and (b) Ucon-salt ATPSs at 23 ºC. Lines are linear regressions of experimental data.

The linearity observed in figure 1 is described as:

$$\ln K = C + E \times n(CH_2) \tag{2}$$

where *C* and *E* are constants which have been previously described in detail (Zaslavsky, 1995). Parameter *E* is a measure of the difference between the different affinities of the two phases for methylene groups, i.e., a measure of the relative hydrophobicity of the phases. Both parameters *C* and *E* were obtained by linear regression. Parameter *E* is related to the free energy of transfer of a methylene group between the phases:

$$\Delta G(CH_2) = -R \times T \times E \tag{3}$$

with *R* being the universal gas constant and *T* the absolute temperature.

$\Delta G(CH_2)$ values calculated from the partition coefficients of the five DNP-amino-acids in the five polymer-salt ATPSs using equations (2) and (3) (Zaslavsky, 1995) are presented in Table 2 together with values from literature (Rodríguez et al., 2007) for comparison purposes.

Table 2: Comparison of $\Delta G(CH_2)$ for six ATPSs at 23ºC

System	**$-\Delta G(CH_2)$, kcal/mol**
PEG-Na_2SO_4	0.153*
PEG-Li_2SO_4	0.167
PEG-$(NH_4)_2SO_4$	0.196
Ucon-Na_2SO_4	0.212
Ucon-Li_2SO_4	0.179
Ucon-$(NH_4)_2SO_4$	0.242

* from Rodríguez et al. (2007).

Ucon-salt ATPSs provide higher values of $\Delta G(CH_2)$ than the corresponding PEG-salt systems. This fact indicates that the Ucon-rich phase is more hydrophobic than the PEG-rich phase. The same conclusion can be obtained from the direct inspection of the PEG and Ucon chemical structure: PEG is an ethylene oxide homopolymer while Ucon is a random copolymer of ethylene oxide and propylene oxide monomers (larger alkyl chain).

The higher relative hydrophobicity of the Ucon-rich ATPSs suggests a more efficient biphasic separation system, with lower cross-contamination between the equilibrium phases. The use of thermo-separating polymers, like Ucon, provides thermal phase separation and simplifies the recycling of polymers. When heated above the critical temperature (about 50ºC) Ucon suffers phase separation into one separate polymer enriched phase and one aqueous solution (Persson et al., 2000). This results in a more suitable ATPSs for use in large scale, continuous processes: Ucon can be recovered and recycled, with a reduction in the production costs.

Abstract

The biocorrosion study attract numerous investigators due to necessity of developing technologies that aims to increase the lifetime of materials used in industries, or the development of new more resistant materials (VIDELA, 2005). So that such fact occurs is necessary a deeper knowledge regarding the mechanisms that involve the formation of biofilms as well as the involved microorganisms in this process, considering the variety of microorganisms species of different regions (FRANÇA et al. 2000). It is estimate that 90% of the microorganisms of the planet live under the form of biofilms and that almost does not exist no surface that is not or it cannot come to be colonized for bacteria (CHARACKLIS and MARSHALL, 1990). This work had for objective to study the biocorrosion in a static system using sea water from a located Thermoelectric Plant in SUAPE-PE, Brazil.

Introduction

The microbiological corrosion or biocorrosion corresponds to the deterioration of metallic materials in consequence of the activity of a variety of microorganisms. During the microbial metabolism they generate aggressive substances, modifying the interface metal/solution that can induce, speed up or inhibit the anodic or cathodic process that controls the corrosion reaction (NATISHAN et al., 1999)

The biocorrosion mechanism involves the growth of microorganism with formation of biofilm wich promotes an increasing in the corrosive process in metallic surface. Generally biofilms is constituted by immobilized cells on the substratum and extracellular polymers produced by the microorganisms (BEECH et al., 2005)

Some metallic substances tend to reach been of lesser energy, changed into metallic oxide or sulfites, what it justifies the intense research to solve the biocorrosion problem. Amongst metals the stainless steel is nobler than the carbon steel, however, still is considered an ideal substratum for the microorganisms settling. Therefore this is normally susceptive to the corrosion located in way contends chlorides (VIDELA, 2005).

In this work the process of biocorrosion was evaluated in the carbon steel AISI 1020 and stainless steel AISI 304L in static system, having as electrolyte the water of the sea proceeding from the port region of SUAPE-PE-BRAZIL.

Materials and methods

Materials

Two types of coupons had been used: carbon steel AISI 1020 and stainless steel AISI 304L, with dimensions 30x25x 3mm and 50 x 50 x 2,5mm respectively.

Treatment of metallic coupons

The metallic coupons had been previously treated before each experiment, through abrasive cleaner with micron glass spheres for removal of incrustations adhered in the surface, treated with isopropyl alcohol for removal of fats, and later treated with acetone. After drying for 24 hours, the coupons had been weighed to tenth of milligram and used in the experiments (TORRES, 2005).

Process Fluid

The sea water samples had been always collected in the same local (SUAPE-PE-BRAZIL) and analyzed under the microbiological aspect.

Microbiologic analyses

I - Quantification of Aerobic Bacteria - they had been quantified through the technique (MPN) method, using saline solution (35,9g/L NaCl) for the dilutions. The incubation was at 30±1ºC for 48 hours (TORRES, 2005).

II - Quantification of *Pseudomonas aeruginosa* - had been quantified through two techniques; (MPN) method for analysis of the planctonics microorganisms, with presumptive assay in medium Asparagine (96h and 35ºC) and confirmative assay in medium Acetamide (48h and 35ºC). The analysis of the *Pseudomonas* sessile was made through Colony Forming Unit (UFC), using the technique "pour-plate", in plates of Petri contends medium for isolation of *Pseudomonas* (*Pseudomonas* isolation agar). The determination of the cellular growth was made after incubation at 30±1ºC for 48 hours (SILVA et al., 2005).

III – Quantification of the Iron-Reducing Bacteria - had been quantified by the technique (MPN), using medium ammoniac ferric citrate, incubation at 30±1ºC for 14 days, protected from the light. The formation of a red coloration caused for the iron oxide formation, characterized the growth of these microorganisms (TORRES, 2005).

IV - Quantification of Anaerobic Bacteria - had been quantified by the technique (MPN) using bottles 10mL of capacity, contend 9,0mL of fluid thioglycollate medium, purged with nitrogen during 20 minutes and 1,0mL of the reducing solution with the inoculum. The incubation was at 30±1ºC for 28 days (TORRES, 2005).

V - Quantification of Sulfate-Reducing Bacteria (SRB) - had been done by the technique (MPN), in the medium modified Postgate E, with incubation at 30±1ºC in the period of 28 the 45 days. The black coloration is consequence of the formation of deposits of iron sulfite (TORRES, 2005).

VI - Quantification of Filamentous Fungi - These microorganisms also was quantified through the Colony Forming Unit (UFC), using the technique "pour-plate", in medium Sabouraud. The incubation was at 30±1°C for 72 hours (TORRES, 2005).

To evaluate the percentage of the microbiological corrosion in coupons was done sterile test with addition of 0.5% of sodic azide.

Biocorrosion Test

The experiments had been done in open static system in glass reactor with dimensions of 50 x 25 x 30 cm³ and useful volume of 34L.

The metallic coupons had been exposed in the sea water and the monitorament of these was made with the exchange of water, each 15 days. Biocupons had been analyzed through loss of mass, rate of corrosion and sessile microorganisms. Also was determined planctonics microorganisms during the process.

Loss of mass and rate of corrosion

The coupons had been weighed before the treatment, when they had been bathed in acid chloridric (26%) solution for 5 seconds, washed in distilled water, neutralized with solution of NaOH 10% (p/v) during 5 seconds and, washed again in distilled water. Finally, the coupons had been immersed in isopropyl alcohol per 5 seconds and, later, in acetone per more 5 seconds. The coupons treated were dried for 24h and weighted (TORRES, 2005).

Results and Discussion

In carbon steel coupons AISI 1020 it was observed presence of different microbial groups on metal surface in function of exposition time. Important microorganisms responsible for the biocorrosion process were present. The iron-oxidants bacteria had reached the maximum value in 30 days (Figure 1). These bacteria are capable to produce flocs and fouling deposits (inorganic and biological) in the industrial water systems and produce cloggings in the extractive industry of oil (GENTIL, 2003).

The concentrations of anaerobes and SRB had increased with time; this should be certainly because of decrease of oxygen in the system, in consequence of its consumption for the aerobic microorganisms and formation of biopolymers that hinder the access for the biofilm base (Figure 1).

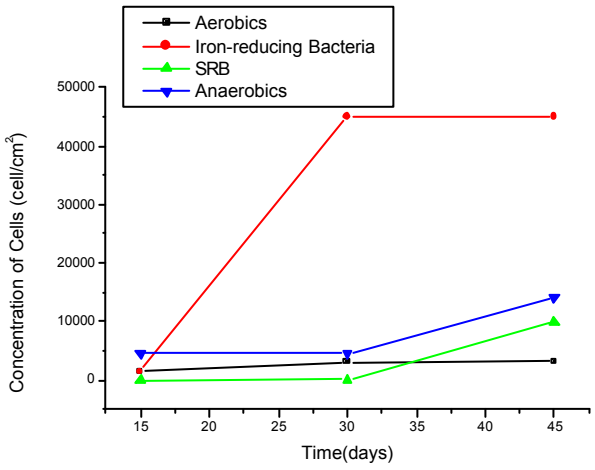

Figure 1 - Populations of aerobic, anaerobic, SRB and iron-reducing bacteria in biofilms formed on steel carbon AISI 1020 coupons, in function of the time of exposition in the system.

The microbial population of *Pseudomonas aeruginosa* and filamentous fungi in carbon steel AISI 1020 remained stable during exposition of coupons at sea water (Table 1).

Table 1 - Concentration of Pseudomonas aeruginosa and filamentous fungi present in immersed coupons in the seawater.

Analysed Coupons	Concentration 15 days	Concentration 30 days	Concentration 45 days
Pseudomonas (UFC/cm^2)	Presence	3x10^2	2x10^2
Filamentous Fungi (UFC/ cm^2)	4	4	6

The formation of not uniform deposits in the surface of carbon steel AISI 1020 after 45 days of exposition in the sea water is presented in Figure 2. It can be observed a thick layer of adhered material in the metal surface probably consisting by microorganisms, extracellular products of corrosion, polymeric substances, organic and inorganic particles that had contributed in the biocorrosion process (WIMPENNEY et al. 2000).

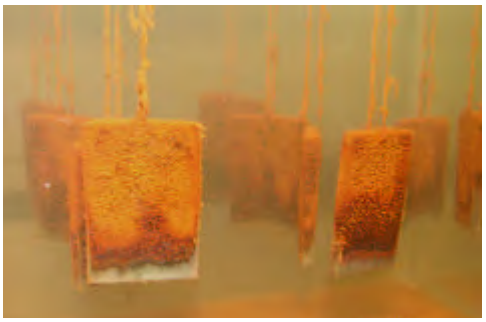

Figure 2 - Formation of biofilm in steel carbon AISI 1020 coupons after 45 days of exposition to the sea water.

The biofilms formed in the surfaces of stainless steel coupons AISI 304L had also shown the presence of different microbial groups. It was observed that sessile bacteria had showed a reduction in its concentration with time, except for SRB and fungi that had presented a small increase (Table 2).

Table 2 - Concentration of microorganisms in the coupons with 90 and 180 days.

Sessile Microorganisms	Aerobics (MPN)	Iron-reducing bacteria (MPN)	Anaerobics (MPN)	SRB (MPN)	*Pseudomonas aeruginosa* (UFC)	Fungi (UFC)
90 days	4,5x10^5	1,4x10^6	1,1x10^5	9	1,9x10^3	1,4x10^1
180 days	4,5x10^4	1,5x10^5	3,0x10^4	1,5x10^1	7,3x10^2	5,7x10^1

Figure 3.1 shows the presence of adhered microbial growth in the coupon surface, inside the reactor. A fungi colony can be observed as the predominant formation of deposits in superior surface of the stainless steel. Figure 3.2 shows the local corrosion after the removal of fungi colony that it was found adhered in the inferior coupon surface. This intense located corrosion was resultant of microorganisms presence that had made it difficult the access of oxygen, probably causing the formation of corrosion for distinguishing aeration. This result showed the tendency of the localized corrosion usually detected in the stainless steel (PANOSSIAN, 1993).

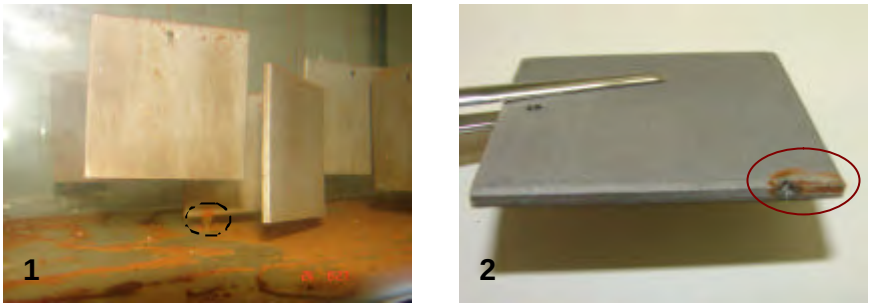

Figure 3 - Presence of microbial growth adhered to the coupon surface (1) and corrosion located in stainless steel coupon 304L after removal of aggregate of microorganisms (2)

Rate of Corrosion

After 45 day of exposition to the sea water, it was observed the presence of all the analyzed microorganisms and a moderate corrosive rate of 0.0882 mm/year in carbon steel coupons AISI 1020 (Figure 4).

The standard analyze, without microorganisms, the corrosion rate was 0.0722mm/year. The proportion of the induced corrosion by microorganisms (MIC) was 18.14%.

Stainless steel AISI 304L revealed itself more resistant, presenting low rate of corrosion (between 0,0007 and 0,0023) in the sea water analyzed (Table 3).

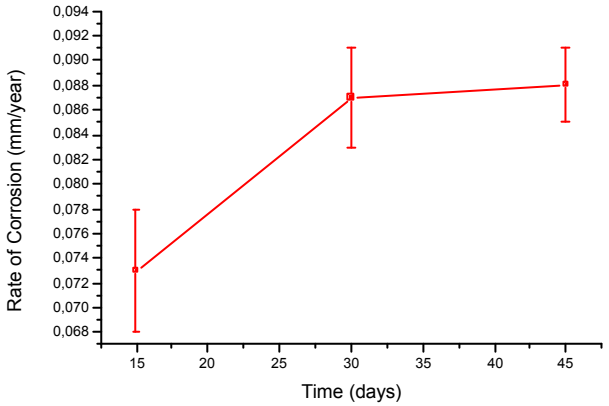

Figure 4 - Rate of corrosion in carbon steel coupons AISI 1020 displayed sea water

The stainless steel coupons 304 L that had been immersed in sea water showed the losses of mass and low rate of corrosion (Table 3). The results shows that the rate of corrosion in the period of 90 days was superior to the one of 180 days. This fact can be justified by the presence of the aggregate of microorganisms in the metal during the period of 90 days.

Table 3 - Rate of Corrosion of the coupons stainless steel AISI 304L

Coupons (days)	Rate (mm/year)	Corrosivity
90	0.0023	Low
180	0.0007	Low

Conclusions

1. The concentrations of anaerobic bacteria and SRB in carbon steel coupons AISI 1020 had increased with time, which is certainly due to decrease of oxygen in the base of biofilm.

2. The filamentous fungi and *Pseudomonas aeruginosa* bacterium had remained steady in the times of exposition of carbon steel coupons AISI 1020 in sea water.

3. The iron-reducing bacteria had presented growth accented in fluids and carbon steel coupons AISI 1020 having actively influenced more in the biocorrosion process.

4. In carbon steel AISI 1020 the biocorrosion percentage was approximately 18.14%.

5. The corrosion rate for the steel carbon AISI 1020 was classified as moderate whereas for the stainless steel AISI 304 L was found as low corrosivity.

6. The presence aggregate of microorganisms in the stainless steel AISI 304L favored an intense corrosion located due to difficulty of the access of the oxygen, causing the formation of the corrosion for differential aeration.

Keywords: Drinking water; Biofilm monitoring; Flow rate; Support material
Topic: Integration of life sciences & engineering

Abstract

Monitoring of biofilm subjected to different process conditions was performed using two distinct bioreactors, Propella™ and flow cell system. Biofilms were grown on polyvinyl chloride (PVC) and stainless steel (SS) coupons under laminar (Reynolds number of 2000) and turbulent (Reynolds number of 11000) flow. The parameters analyzed were culturable cells, using R2A, and total bacteria, which were assessed using a DNA-binding stain coupled with epifluorescence microscopy. The impact of the different operating conditions in the studied parameters was established after the biofilms reached the steady-state. It was found that the biofilm steady-state was achieved 3 d after the starting of operating conditions for turbulent flow and for both bioreactors and adhesion surfaces. Under laminar flow it was only achieved 6 d after. The number of total bacteria was invariably higher than the culturable cells. The number of total and culturable bacteria in turbulent flow-generated biofilms were similar in both bioreactors, regardless the adhesion surface tested. Under laminar flow, the Propella™ bioreactor allowed the formation of steady-state biofilms with a higher number of total and culturable bacteria than those from the flow cell system. Comparing the effect of the flow regime on biofilm accumulation, only turbulent flow-generated biofilms formed on the flow cell system had a higher amount of total and culturable bacteria than those formed under laminar flow. In terms of adhesion surface effect on steady-state biofilms, a higher number of total and culturable cells were found on PVC surfaces comparatively to SS when biofilms were formed using the flow cell system. Biofilm formation on PVC and SS was similar in the Propella™ system for both flow regimes.

1-Introduction

The dynamics of the microbial growth in drinking water networks is very complex, as a large number of interacting processes are involved. Many problems in drinking water distribution systems (DWDS) are microbial in nature, including biofilm growth, nitrification, microbial mediated corrosion, and the occurrence and persistence of pathogens (Camper 2004; Emtiazi et al. 2004). Biofilms are suspected to be the primary source of microorganisms in DWDS that are fed with treated water and have no pipeline breaches, and are of particular concern in older DWDS (Simões et al. 2006). By adopting this sessile mode of life, biofilm-embedded microorganisms enjoy a number of advantages over their planktonic counterparts. One advantage is the ability of the extracellular polymeric matrix, they excrete, to capture and concentrate a number of environmental nutrients, such as carbon, nitrogen and phosphate (Simões et al. 2006). Another advantage to the biofilm mode of growth is that it enables resistance to a number of control strategies (Simões et al. 2005). DWDS disinfection with chlorine dioxide and chlorine, for example, can reduce the concentration of planktonic bacteria, but have little to no effect on the concentration of biofilm bacteria (Gagnon et al. 2005). This inherent resistance to antimicrobial factors is mediated through very low metabolic levels and drastically downregulated rates of cell division of the deeply embedded

microorganisms. Biofilms act as a diffusion barrier, slowing down the penetration, to some antimicrobial agents (Simões et al. 2005). Other important advantage of the biofilm mode of growth is the potential for dispersion via detachment. Under the direction of fluid flow, detached microorganisms travel to other regions to attach and promote biofilm formation on clean areas (Codony et al. 2005).

Drinking water pipes inner-surfaces are invariably colonized by biofilms, regardless the presence of a residual disinfectant. In addition to the possibility of causing corrosion, taste and odour problems, biofilms control the microbiological contents of the distributed water and are a potential source of pathogens (Szewzyk et al. 2000). In fact, biofilms formed within potable-water systems contain bacterial pathogens such as *Legionella pneumophila* and coliforms of intestinal and nonintestinal origin (World Health Organization 1993). Furthermore, protozoa are commonly found within water distribution systems and have been associated with the persistence and invasiveness of pathogens (Simões et al. 2007a). Such findings implicate the importance of maintaining a continuous residual disinfectant in DWDS. Moreover, the examination of a DWDS reveals the complexity of such a technical system. There are not only many different materials used for the transportation and regulation of the water flow but also dramatic variations in the flow conditions between different locations. Obviously, microorganisms face a diversity of habitats with distinct physicochemical and nutritional conditions during treatment, storage, and distribution of drinking water.

The purpose of the present study was to evaluate the drinking water biofilm formation by drinking water autochthonous bacteria on stainless steel and polyvinyl chloride, two support materials commonly used on drinking water networks, under different water flow rates, using the Propella™ bioreactor and the flow cell system.

2-Material and Methods

2.1-Bioreactors and biofilm monitoring

In this study, monitoring of drinking water biofilm subjected to different conditions was performed using two distinct bioreactors, flow cell system and Propella™. The configurations of these bioreactors are presented in Figure 1.

The drinking water source was from the public network in Braga (North of Portugal). Briefly, tap water was collected in a reservoir, which was connected to one of two consecutive granular activated carbons (GAC) filter columns. It has been shown elsewhere that the first GAC filter eliminates free chlorine and biodegradable matter contained in the tap water, while the second is a biological activated filter providing a continuous bacterial inoculum to the bioreactor (Morin and Camper 1997). To avoid the presence of large carbon particles released from the columns, two filters (pore sizes 20 µm and 5 µm) were placed between the second GAC filter and the mixing tank. This tank supplied a constant inoculum at a flow rate of approximately 0.02 L h^{-1} into each of the flow cells or 1.12 L h^{-1} into the Propella™, in order to obtain the adequate dilution rate and similar to both bioreactor systems. Absence of free chlorine in the mixing tank was certified by regular sampling, using the free chlorine ion specific meter HI-93701 (Hanna Instruments, USA).

Biofilms were grown on polyvinyl chloride (PVC) and stainless steel ASI 316 2R (SS) coupons. The water flow rate through the bioreactors was controlled by recirculating the water by means of recirculation pumps (flow cells) or by means of motor for water agitation (Propella™). The biofilms were developed under laminar (Reynolds number of 2000) and turbulent (Reynolds number of 11000) flow rate. Temperature in the both bioreactors was maintained at 20 ± 1 ºC by an external refrigeration mechanism (Thermomix® BU, B. Braun – Biotech SA).

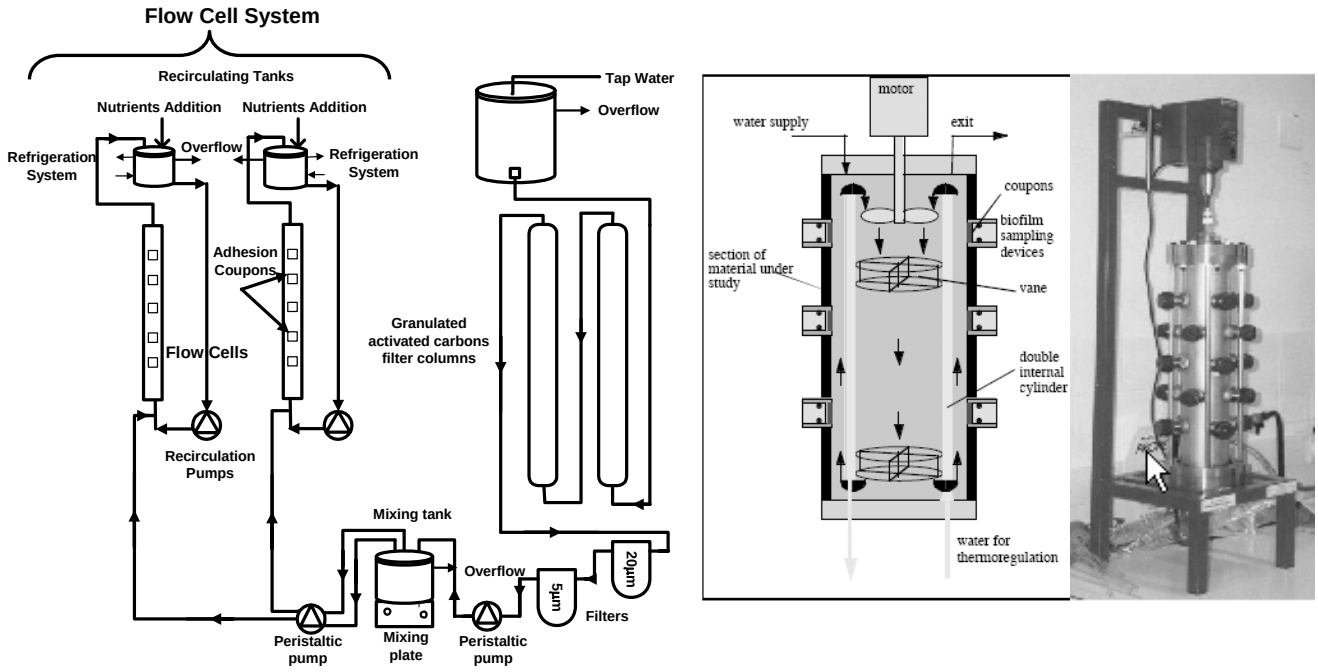

Figure 1 – Experimental set-ups, showing the GAC filter columns and the flow cell system (a); and the Propella^{TM} bioreactor (b).

2.2-Biofilm sampling

Biofilm sampling was made from the top to the bottom of the bioreactors under aseptic conditions and the coupons removed were substituted with new ones that were previously cleaned, immersed in ethanol (70 % v/v) for 30 min, and rinsed in sterile distilled water. The removed coupons were gently washed with sterile saline phosphate buffer (pH=7.0) to remove loosely attached microorganisms and scraped with a scalpel into 15 mL glass tubes containing 10 mL of sterile phosphate buffer. Before serial dilutions, biofilm suspensions in the tubes were vortexed for 2 min and used to assess both colony forming units (CFU) and total cell counts (TB).

2.3-Culturable and total cell counting

CFU`s were evaluated by standard culture methods on R2A (Oxoid, UK) prepared according to manufacturers instructions. Triplicate plates were used for each dilution and for each tested biofilm. CFU's were counted after 15 d of incubation at 20 ± 3 ºC, and the results were expressed as CFU cm^{-2}. TB were obtained by filtering the adequate volume (up to 10 mL as a function of the bacterial concentration) through a 25 mm black Nucleopore® polycarbonate membrane with a pore size of 0.2 µm (Whatman, UK). Before the filtration step, 2 % (v/v) formaldehyde (Merck, Germany) was added to the solution for sample fixation and preservation. After filtration, cells in the membrane were stained with 100 µg mL^{-1} of 4,6-diamino-2-phenylindole (DAPI) (Sigma, Portugal) for 5 min and the preparations were stored at 4 °C for up to 7 d in the dark, before visualization. No significant decay of fluorescence was noticed during this time span. Cells were visualised under an epifluorescence microscope (Carl Zeiss, Germany) equipped with a filter sensitive to DAPI fluorescence (359 nm excitation filter in combination with a 461 nm emission filter). A total of 20 fields were counted and the average of three membranes was used to calculate total cells per cm^2.

2.4.-Statistical analysis

Paired t-test analyses were performed to estimate whether or not there was a significant difference between the results obtained. Statistical calculations were based on confidence level equal or higher than 95%.

3-Results and Discussion

Biofilms constitute a protected mode of growth that allows microorganisms to survival in hostile conditions, being their phenotype significantly different from their planktonic counterparts. Their development, behavior and population characteristics are strongly influenced by many environmental factors and by intrinsic biological properties (Sauer and Camper, 2001; Purevdorj et al. 2002). From the most important environmental factors affecting biofilm structure and behaviour are the velocity field of the fluid in contact with the microbial layer and the support material for bacterial adhesion and further biofilm development (Vieira et al.1993; Stoodley et al.1999; Simões et al. 2006). Hydrodynamic conditions will determine the rate of transport of cells, oxygen and nutrients to the surface, as well as, the magnitude of shear forces acting on a developing biofilm (Vieira et al. 1993). Regarding the effects of the support material, microbial attachment will occur most readily on surfaces that are rougher, more hydrophobic, and coated by surface conditioning films (Donlan, 2002).

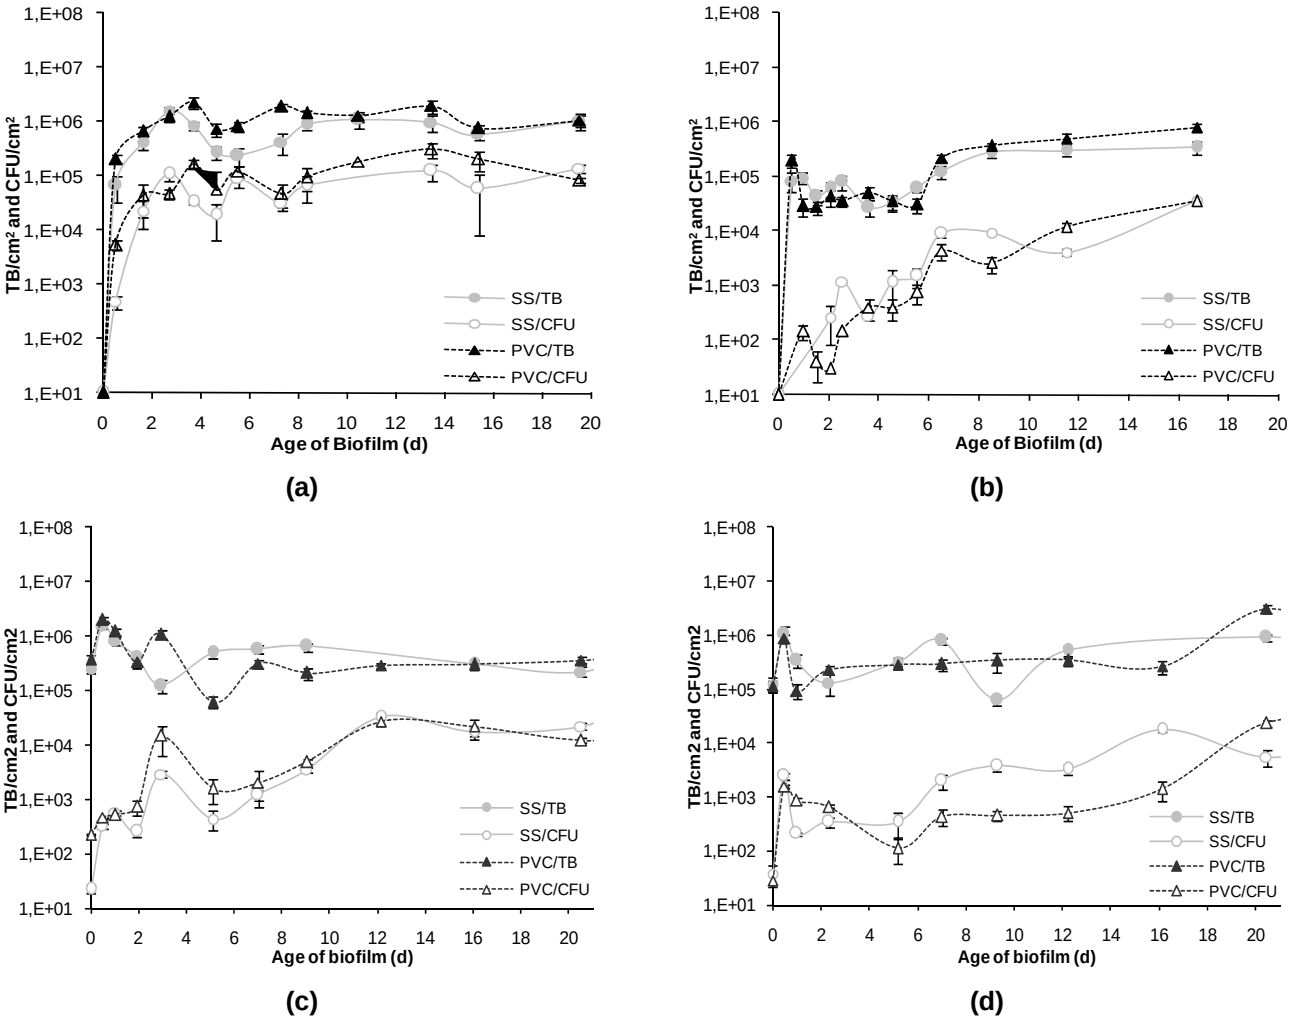

Figure 2 – Kinetics of biofilm growth obtained for the different conditions with the two bioreactors. Biofilm accumulation along time (assessed by TB and CFU) on SS and PVC surfaces. (a) turbulent flow and (b) laminar flow in flow cell bioreactor. (c) turbulent flow and (d) laminar flow in the Propella^{TM} bioreactor.

Biofilm accumulation in all experiments, expressed both in CFU and TB, increased markedly in the first few days, following a sigmoidal curve (Figure 2). Biofilm steady-state was achieved 3 d after the starting of operating conditions for turbulent flow conditions and for both bioreactors and adhesion surfaces. Under laminar flow conditions, it was only achieved 6 d after. For those cases, the number of total bacteria was invariably higher than the culturable cells (differences always higher than 2 log). It has long been recognized that the use of culture-based enumeration techniques may significantly underestimate the numbers of viable cells. Several reasons may account for this difference: the presence of starved or injured cells or potentially viable but nonculturable cells (VBNC) that are not able to initiate cell division at a sufficient rate to form colonies; inadequate culture conditions; aggregation of bacteria that can lead to the formation of one colony from more than one cell, thereby underestimating the total number of cells (Banning et al. 2002). However, total and culturable bacteria in turbulent flow-generated biofilms were similar in both bioreactors, regardless the adhesion surface ($p > 0.05$). This result suggests that increased hydrodynamic stress favours biofilm bacteria culturability. Vieira et al. (1993) found that mass transfer limitations existed in a higher extent in biofilms formed under laminar flow than for turbulent conditions. Consequently, the higher oxygen rate and transport of substrate, even if at very low levels in DWDS, from the fluid to the biofilm (mass transfer effects), should favour microbial metabolism and cell replication. Comparing the effect of the flow regime on biofilm accumulation, it was only found for the flow cell system that turbulent flow-generated biofilms had a higher amount of total and culturable bacteria than those formed under laminar flow ($p < 0.05$). This result is in agreement with previous studies (Stoodley et al. 1999; Simões et al. 2007b), with single and mixed species biofilms formed on flow cell systems, showing that biofilms formed under turbulent flow had a significant higher cell density than the laminar counterparts. Turbulent and laminar flow-generated biofilms formed on the Propella™ bioreactor had comparable cell densities. Moreover, the Propella™ system allowed the formation of steady-state laminar flow-generated biofilms with a higher number of total and culturable bacteria than those formed on the flow cell system ($p < 0.05$). In fact, there are significant differences on the design of the used bioreactor systems that can account for the differences obtained. For example, the hydrodynamic stress is obtained by distinct mechanisms when using Propella™ bioreactor (agitation by means of a rotating device system) and the flow cell system (fluid flow). In terms of adhesion surface effects, in the flow cell system, a higher number of cells formed biofilms on PVC surfaces comparatively to SS ($p < 0.05$), while biofilm formation on PVC and SS was similar ($p > 0.05$) in the Propella™ system, for both flow regimes. In a previous study (Simões et al. 2007c), it was demonstrated that the tested materials had similar physico-chemical characteristics, such as hydrophobicity, and both are prone to colonization by drinking water isolated bacteria. Consequently, it was expected a low biofilm data variability as a consequence of adhesion surface differences.

3-Conclusions

The development and validation of reliable biofilm monitoring techniques is required in order to mimic real environmental situations using laboratorial systems. This work demonstrates that distinct bioreactor configurations provide different biofilm data. In fact, the use of PVC or SS as adhesion surfaces and distinct hydrodynamic conditions lead to biofilm accumulation variability in terms of CFU and TB when using the Propella™ or the flow cell bioreactors. Moreover, this study highlights the need for a deeper understanding of how the large spectrum of conditions interact and affect biofilm formation potential and accumulation with the final purpose of predicting the total and culturable bacteria attached to real drinking water distribution pipes, based on the system characteristics. Although the practical use of these conclusions by drinking water network companies is still limited, the information provided here might be used as a framework for future studies.

Keywords: *Nannochloropsis gaditana*, culture conditions, fatty acids, pigments, aquaculture
Topic: Integration of life sciences & engineering.

Abstract

The influence of different media composition on the *Nannochloropsis gaditana* growth rate, pigments and fatty acids production, was compared with the goal of selecting the most appropriate conditions for scale-up. The simple use of natural resources, such as sun light radiation without precautions, may not be the best way to achieve high productivities. The synergy (or cross effect) between the light intensity and the daily temperature variation has a stronger effect than both factors dissociated, and it must be the main criterion for the selection of the culture system (either indoor or outdoor). Increased concentrations of $MgSO_4$ (6-9 mM) in the culture medium favoured the cell density and chlorophyll yield but not the fatty acids and chlorophyll cell content. pH control is essential for large scale cultivation, that must use sun light but avoiding large temperature variations, as well as light inhibition. The production of EPA, as a structural fatty acid, was shown to be associated to the cell growth and not directly obtained from reserve lipids.

1 Introduction

Important drawbacks in aquaculture hatcheries are the need of large space facilities and the associated costs to produce microalgae in large quantities. The use of new and versatile photobioreactors, as well as the optimization of culture conditions to produce enriched microalgal biomass, is the preferred way to improve the production yield on-site with reduced costs (Tredici and Materassi, 1992). Simultaneously, microalgae must have particular attributes for aquaculture purposes, such as high growth rates, and must be not very sensitive to fluctuations in temperature, light radiation or nutrient composition, that usually occur in open and outdoor cultivation systems. They must also have a good nutritional composition that might be transferred up the food chain.

Nannochloropsis gaditana is employed in aquaculture hatcheries as the start of the food chain, and it is recognized as a source of pigments and polyunsaturated fatty acids. Its high content in EPA (C20:5n3) is particularly attractive, from a dietary point of view. Rotifers that consume the microalgae carry the fatty acids to the fish larvae. However, the benefits of those compounds must be economical balanced. In fact, the environmental microalgae culture conditions, such as temperature, pH, availability of essential ions in the medium and light radiation intensity are the main factors that strongly affect both the microalgae growth and the pigments and PUFAs production yields. Finding the optima of those factors, in order to maximize the metabolite productivity, is not an easy task, mainly because their crosslinked interferences.

2 Material and Methods

2.1 Growth conditions

Nannochloropsis gaditana was obtained from Necton (Portugal). It was grown in three culture media: (i) the synthetic seawater medium (Henriques et al. 2007), referred here as industrial medium (IM); (ii) the F/2 medium (Guillard and Ryther 1962) made by filtered sea water, added with a buffer (Tris/HCl) and stock vitamins (biotin and B12); (iii) the so called enriched medium (EM), when the IM medium was reinforced with $MgSO_4$ to evaluate the influence of the magnesium concentration in chlorophyll production.

The growth was autotrophic with CO_2 from the atmosphere as the unique carbon source, reaching the culture through a cotton stopper or by bubbling. The culture systems included Erlenmeyer flasks and tubular bubble reactors. Erlenmeyer flasks were illuminated by direct or indirect sun light, and the cultures were run either at room or outdoor temperatures. Tubular bubble reactors with a volume of 0.7 L (glass tubes with 0.7 m length and 0.05 m diameter) sparged with air at 120 mL min^{-1} flow rate, were operated under two ranges of temperature (18 and 22±1 ºC) and two light regimes with *c. a.* 10/14h light/dark cycles.

2.2 Analytical methods

Cell density was evaluated by measuring the optical density of the culture at 540 nm in a Beckman DU Series 600 spectrophotometer. Absorbance was correlated to the cell number concentration by counting cells with a Neubauer Hemocytometer. The cellular amount of chla and carotenoids was evaluated through the Lichtenthaler (1983) correlation, referred by Welburn (1994), using methanol as extraction solvent for 24 h at 8 ºC. The fatty acids methyl esters (FAME) were obtained by transesterification of lyophilized cells, according to the Sato and Murata (1988) method, and analysed by GC using C19:0 as an internal standard. FAME samples were analyzed by a TREMETRICS 9001 chromatograph with a FID detector and a DB225 J&W SCIENTIFIC capillary silica column.

3 Results and Discussion

3.1 Effect of magnesium concentration

Magnesium is expected to be a potential precursor to chlorophyll production bust not necessary to fatty acids production. To evaluate the effect of Mg concentration in chlorophyll *a* (chla) and fatty acid production in *Nannochloropsis gaditana* an industrial medium (IM) ([$MgSO_4$] = 0.02 mM) and an enriched medium (EM) ([$MgSO_4$] = 1 mM) were used.

The cell density, as well as the chla concentration, increased with Mg concentration in the enriched medium (Fig. 1a). The greater availability of magnesium in the culture medium drove the cell metabolism to the production of a higher content of chlorophyll.

However, a reduction of total fatty acids produced with the use of additional magnesium (EM) was observed. In this last case only 14.6% mg mg^{-1} DW (dry weight) of total fatty acids was achieved compared to 42.5% mg mg^{-1} DW in the IM (Fig. 1b). The larger availability of magnesium induced the cellular metabolism to produce pigments but did not favoured the accumulated of lipids. Also the content of EPA followed the same trend, with 9.1% mg mg^{-1} DW in the IM assay and only 2.2% mg mg^{-1} DW in the EM assay.

The results obtained with higher concentrations of magnesium (1, 3, 6 and 9 mM, data not shown) confirmed the positive influence on the cell density achieved.

However, the chlorophyll content increase in the culture was found to be non linear with the Mg concentration. The highest Mg concentration tested (9 mM) showed the lowest relative increase of chlorophyll in the culture. On the other hand when cell content of chla was evaluated, a significant decrease of chlorophyll per cell was observed with the increase of Mg concentration. These results suggest that Mg may interfere in a deeper way with the

protein formation (resulting in higher cell densities) than with chlorophyll production, corroborating the results achieved by Zielinski and Price (1978) with other species, even for higher Mg concentrations. Therefore, the chla yield increase associated to Mg comes from the greater of cell density, more than from a higher cell content.

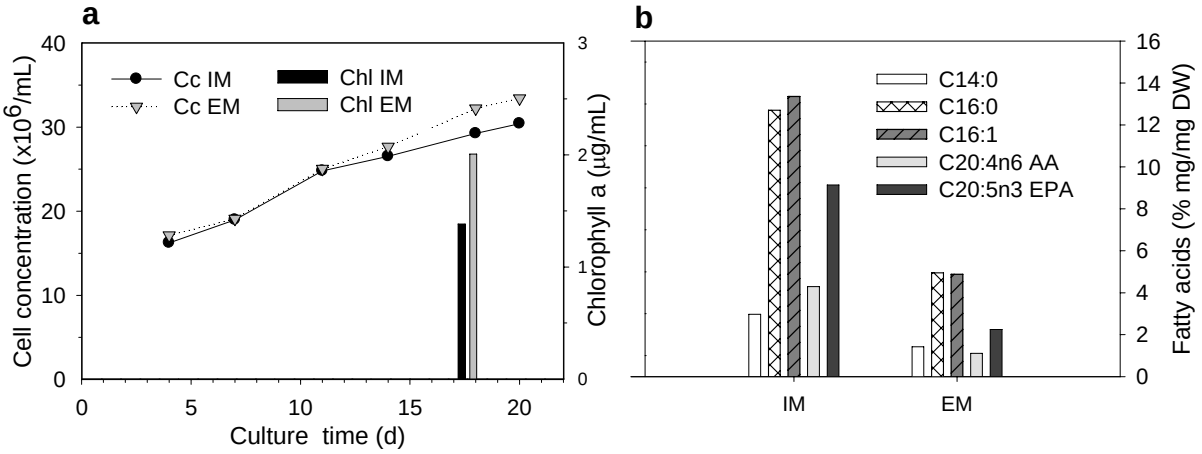

Figure 1. Effect of Mg availability on: (a) cell concentration (Cc) and chlorophyll a content (Chl); (b) fatty acid composition of the cells. IM – Industrial medium ([$MgSO_4$] = 0.02 mM); EM – Enriched medium ([$MgSO_4$] = 1 mM). Natural light illumination at 21 ºC.

3.2 Effect of culture medium composition

In this section some of the control variables were jointly tested by using two different media: the IM and the F/2. The main differences between the IM and the F/2 media were the buffering with Tris/HCl, the use of filtered sea water (instead of artificial sea water) and the increment with additional vitamins, in the second one.

After the two days lag phase for both cultures, cell growth rate was clearly favoured with the F/2 medium (data not shown). The main influence must come from the use of a buffer in the F/2 medium that allows a constant pH. In fact, the pH variations with IM medium (without any pH control) were really strong (from 6 to 9 in 20 days). Most of microalgae cultures are affected by pH variations due to the consumption of carbon dioxide during the photosynthesis and also the metabolites excreted by cells. This variation may be prejudicial both to the culture growth and to the production of pigments. In previous works, Zittelli et al. (1999) and Rocha et al. (2003) concluded that the use of a buffer is beneficial for the cell growth of *Nannochloropsis* strain, with an optimum pH value between 7.8 and 8.2.

Fig. 2 shows that the F/2 medium clearly favours the pigment concentration in the culture (*c.a.* 150% increase in chlorophyll and 155% in carotenoids), which follows the cell growth trend. When the specific content of pigments is evaluated, it is confirmed that F/2 medium is much more favourable compared to the IM medium. A decrease in pigment cell content during the second phase of the culture period that occurs in the F/2 medium, may be related to the fast growth rate promoted by using favorable growth conditions (vitamins and constant pH). In this case, cells do not need to produce a significative amount of pigments to make the photosynthetic process more efficient. Also, the shadow effect created by cells one another may explain the reduction of the specific content of pigments when a large concentration of cells is achieved.

Medium buffering, the use of filtered sea water and the addition of vitamins improve the cell growth and the production of pigments in the cells. However, taking in mind the use of microalgal biomass, the main feature may be the nutritional value in pigments itself, or the overall concentration of live food to be used in hatcheries. When the algal colour attraction is

an important goal to reach, microalgae cells must be harvested sooner (before a plateau in cell density is reached).

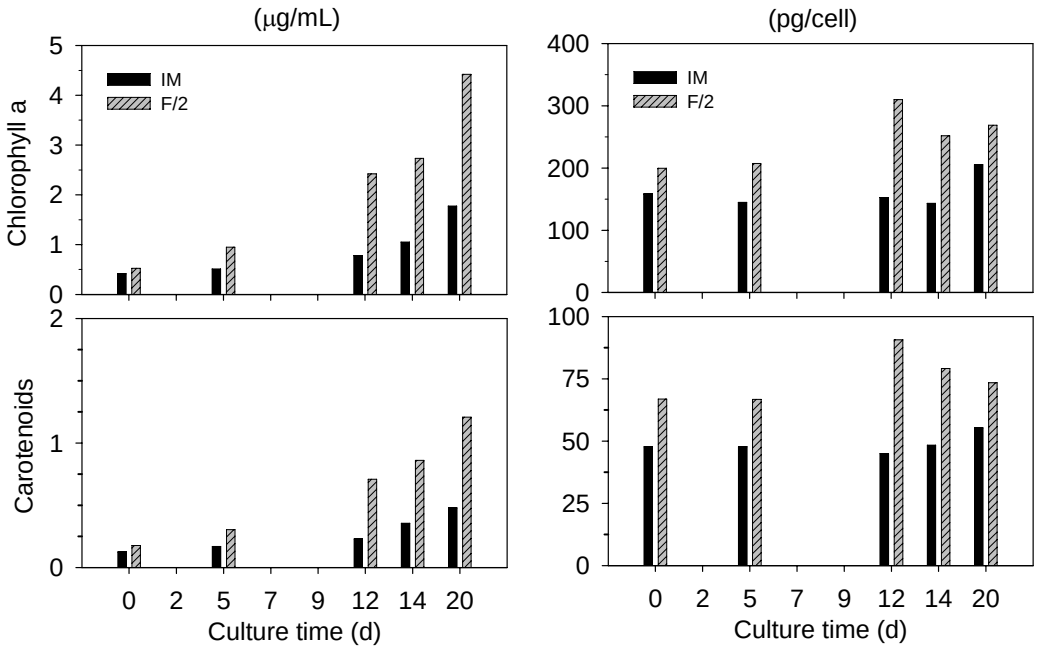

Figure 2. Effect of the culture medium composition on the chla and total carotenoids content (volumetric, left graph and specific, right graph). Cultivation in Erlenmeyer flasks. IM – Industrial medium. F/2 – Buffered medium with filtered sea water and vitamins. Temperature range: 15–20 ºC. Indirect sun light illumination, indoor.

3.3 Effect of daily temperature changes

Temperature and light intensity interactions are strongly linked in the Nature. In order to reduce temperature variations from sun light cycle, two experiments were performed in Erlemmeyer flasks submitted to the same light cycle and intensity, but in outdoor and indoor environments (separated by a glass), during winter time.

Cultures submitted to large temperature variations (outdoor) were not favoured, neither to the growth rate nor to the chla content. Seven days after the inoculation, the outdoor culture was yellow-green and at the 10th day it was completely yellow, showing chlorophyll degradation. A significative growth was visible in the indoor culture, under the same light regimen, but at a more constant temperature around 21 ºC. The observed results confirm that although the abundance of light is a primary need to phototrophic production, the range of daily temperature variations is also very important, mainly because direct light inhibition phenomena are stimulated by temperature (rather than the inconvenience of outdoor low temperatures, during the night, that even reduce the respiration phenomenon activity).

The total amount of fatty acids at the indoor cultivation was higher (42.5% mg/mg DW) than the one obtained in outdoor (26.2% mg mg^{-1} DW). Temperature variation along the daily cycle was not beneficial to the production and accumulation of lipids. Although the biomass cultivated indoors had a larger amount of EPA (9.1% mg mg^{-1} DW), its relative percentage with respect to the total lipid concentration was higher at outdoors. Cell protection from environmental stress can be pointed out as one of the factors that contributed to this behaviour. In fact, EPA is a structural fatty acid associated to the microalga cell wall.

Although the simultaneous temperature and illumination effects are not yet totally understood in outdoor systems, exposed to daily and seasonal variations, our results confirm the ones obtained by Zittelli et al. (1999), that the minimum temperature achieved during the night influences both the quantity and composition of total fatty acids.

3.4 Influence of light intensity and temperature in the fatty acids metabolism

Some bioprocesses are run under sequential two growth phases, first promoting the cell growth rate, and afterwards submitting the cells to some kind of stress to induce the production of interesting metabolites. Previous work (Henriques and Rocha 2006) suggested the increase in EPA content of cells exposed both to low light intensity (1.52 W m^{-2}) and low temperature (*c.a.* 18 ºC).

In order to evaluate the effect of a change in environmental conditions, such as light intensity (constant or variable during the illuminated period), as well as a temperature decrease, on the polyunsaturated fatty acids metabolism, a culture with a bubble column photobioreactor was done. This culture was performed under two distinct growth phases: the first one with natural illumination supplemented with two fluorescent lamps (18 W each); in the second one the photobioreactor was exclusively submitted to artificial illumination. For both phases the light/dark regime was 10/14h. Daily natural oscillations in light intensity occurred in the first part of the culture, while a light intensity of 5.85 W m^{-2} was kept constant during the illuminated period of the second phase (Fig. 3). Temperature decreased from 22 ± 2 ºC in the first phase to 18 ± 1 ºC in the second one.

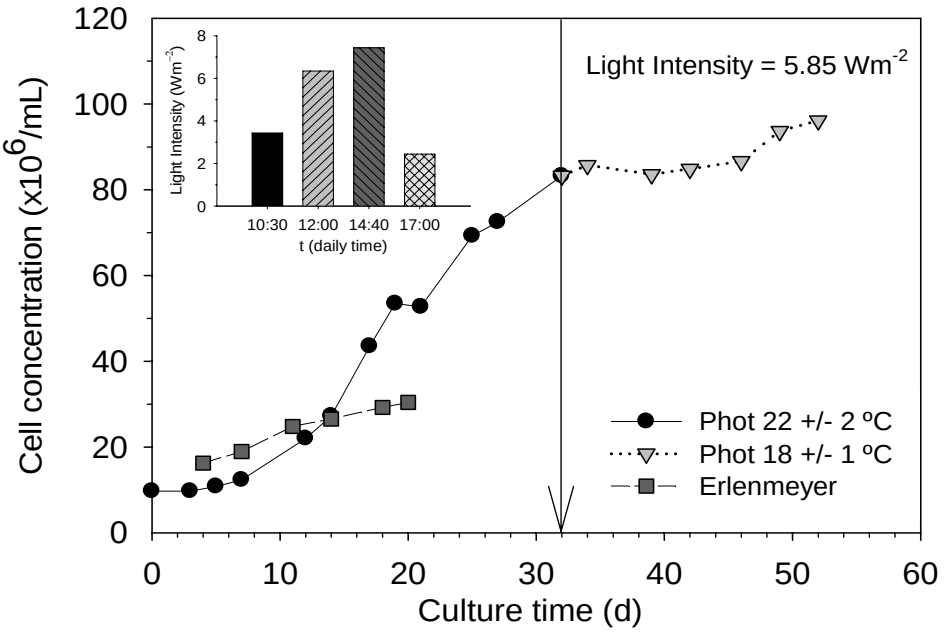

Figure 3. Cell concentration in photobioreactor and Erlenmeyer cultivation (light/dark cycles = 10/14h); IM medium.

Cell growth rate in the photobioreactor was higher than in Erlenmeyer flasks (Fig. 3), and at the 32th day the culture was submitted to a lower temperature. Although the average light intensity was kept constant in both phases of the culture, the light distribution was deficient in the last one because lamps were static and only one side of the photobioreactor was illuminated. Natural illumination decreased the shadow effect of the cells, that surely happened with artificial illumination. Agitation promoted by bubbling in the photobioreactor minimized the light deficiency in the culture; nevertheless it could not totally eliminate this drawback and light limitation was probably the main factor responsible for the lower cell growth in the second phase.

The change of temperatures and light conditions reduced not only the cell growth rate, as expected, but also the total fatty acids and the EPA contents. PUFA's act mainly as structural

fatty acids associated to cell membranes, and their synthesis was not favoured by transformation from saturated or mono-unsaturated fatty acids (which main role is reserve lipids), at the stationary growth phase.

In fact, the consumption of some lipidic reserves must have occurred, because a reduction of total fatty acids from 21 to 17% mg mg^{-1} DW was observed, probably used for cell maintenance. Structural lipids in this microalga are closer to primary metabolites and their production must be stimulated during the exponential growth phase.

These results show that the synergy of environmental factors is important, because their combined effect may lead to opposite results from the ones obtained when each factor is tested individually.

Topic: Systematic methods and tools for managing the complexity.

Abstract

The ability to control bioprocesses at their optimal states is of considerable interest to modern fermentation industries. The aim is to reduce production costs and increase yield while at the same time maintaining the quality of the metabolic products. The objetive of this paper is to apply fuzzy logic to the Penicillin G acylase (PGA) production process. PGA hydrolyzes penicillin G to yield 6-aminopenicilanic acid (6-APA) and phenyl acetic acid. 6-APA is an important raw material, used to produce semi synthetic β-lactam antibiotics. Several experiments were carried out in a bench-scale bioreactor with diferent experimental conditions. The fuzzy algorithm could accurately infer the time for bioreactor harvesting and the output linguistic variable “stop cultivation” was defined between 0 and 100% certainty. The best experimental result was obtained when the dissolved oxygen concentration was maintained close to 0.5% of saturation.

1 Introduction

Penicillin G acylase (E.C.3.5.1.11) is an enzyme of great importance for the pharmaceutical industry, which is used in the production of 6-aminopenicilanic acid (6-APA), a key component for the synthesis of β-lactam antibiotics. There are some microrganisms that produce this enzyme, and recombinant *Escherichia coli* has been used for industrial applications. *Bacillus megaterium* is one of the microorganisms that excretes this enzyme to the medium. As a consequence, separation and purification steps are simplified (Silva et al., 2006; Chandel et al., 2008).

During PGA production, variables such as cell and enzyme concentrations are determined by off-line laboratory analysis, commonly measured only after long delays. Classical inference and control techniques, however, many times are not sufficient to reach reasonable results due to the inherent complexity of these processes. The use of advanced non-conventional techniques is necessary to overcome these difficulties (Shügerl, 2001) and considerable attention has been focused on the development of on-line, software-based state estimators (the so-called software sensors), and the fuzzy logic system presented here is one example (Sousa Jr and Almeida, 2001; Fernandes et al., 2007).

Fuzzy logic refers to a method which tries to embed intuitive and heuristic knowledge of an expert human operator about a particular system into a mathematically justified representation. The essence of this method is a set of IF–THEN rules manipulating the input–output relationship of a system, which is usually represented in linguistic terms, based on the fuzzy set theory (Zadeh, 1965). The promising capability of this method is that it may deal with systems with significant complexity, especially with regard to uncertainties, vagueness and incompleteness (Hisbullah et al., 2003; Nucci et al., 2006).

* Corresponding author. Tel + 55 16 3351-8002. E-mail:ajgcruz@ufscar.br

Various control strategies with fuzzy logic have been developed to control fermentation processes in the literature (Alfafara et al., 1993; Shiba et al., 1994; Sousa Jr and Almeida, 2001; Hisbullah et al., 2003; Karakuzu et al., 2006). The most evident advantage of the fuzzy modeling and control is to organize expert knowledge about the relevant process. Another advantage of this technique is that it does not need detailed mathematical description of the process. It is therefore an adequate intelligent controller.

The aim of the present work is to find the best experimental condition during PGA production process and at the same time to use of a fuzzy logic algorithm (programmed in MatLAB®) to infer the time for bioreactor harvesting. Accurate determination of the moment to begin the harvesting operation is very important for minimizing industrial costs, reducing dead times and avoiding unnecessary degradation of the product during the final stages of a batch or fed-batch cultivation.

2 Material and Methods

The microorganism employed was *B. megaterium* ATCC 14945 from Fundação Tropical (Campinas, SP, Brazil). For inoculum preparation (in $g.L^{-1}$): salt solution (0.2), cheese whey (7.0) and a solution of pool of seven amino acids: alanine (0.71), aspartic acid (2.31), lysine-HCl (0.95), serine (0.83), threonine (0.28), arginine (0.95) and glutamic acid (3.98). For production medium ($g.L^{-1}$): the same solution of amino acids (10.0), salt solution (0.5), cheese whey (19.6), and phenyl acetic acid (2.7) as inductor.

The experiments were carried out in a 2-liters bioreactor (Applikon®) using batch or fed-batch operation. Temperature was kept at 30°C, airflow at 1 vvm and the concentration of dissolved oxygen (DO) was mantained/controled in values between 0 and 20% of the saturation (by the automatic manipulation of stirrer speed via PID control). The bioreactor was coupled to a data acquisition system (National Instruments®) and on-line variables were stored each 10 seconds (pH, temperature, dissolved oxygen concentration, stirrer speed and molar fractions of carbon dioxide in the effluent gas).

Cultivation assays started with the incubation of 15 ml of cell spores in 135 ml of culture medium for 12 h, 300 rpm at 30°C (1,000 ml shake flasks). The inoculum was 10% of the reactor volume. The enzyme activity was determined by colorimetric PDAB-method (Balasinghan *et al.* (1972)) and the cell concentration by optical density (Nucci et al., 2007). Further details about the compostion, procedure and laboratory analyses can be found in Silva et al., 2006 and Nucci et al., 2007.

3 Methodology

Fuzzy set theory, proposed by Zadeh (1965), can deal with the vagueness and uncertainty of human knowledge and with noisy on-line data, and it allows the representation of the system using linguistic terms (*very slow*, *slow*, *fast*, *very fast*, and so on) to develop causal relationships between input and output variables. In general, qualitative information is both imprecise and uncertain. Unlike classical set theory, which crisply classifies the elements of a set (0 or 1 pertinence), a fuzzy set has an ability to classify elements into a continuous realm using the concept of degree of membership. The characteristic function or membership function is not only 0 or 1, but can aasume values in between (Tahera et al., 2008). A membership function is a curve that describes how each point in the input space is mapped to a membership value (or degree of membership).

The first step in designing a fuzzy control is to identify fuzzy input and output monitoring variables. During PGA production process by *B. megaterium* 14945, a strong relationship was observed between experimental enzyme activity and carbon dioxide concentration in the effluent gas. The fuzzy logic algorithm presented here, with 13 rules (Table 1), was written in MatLAB® and implemented in a LabVIEW® environment. Data strings were exchanged in real time between the MatLAB program and the data acquisition software, which was coupled to the bioreactor. The typical architecture of a fuzzy logic algorithm is comprised of four

principal components: *Fuzzifier*, *Fuzzy rule base*, *Inference engine* and *Defuzzifier*. More details about fuzzy logic can be found in Zadeh (1965) and Lee (1990).

Several variables were tested to discovered the best fuzzy inputs (batch time, carbon dioxide concentrations in the effluent gas, stirrer speed, pH and derivates of carbon dioxide concentration and pH) and the results show that batch time, carbon dioxide concentration and its derivate were the best choice. All the rules include all the input variables, each one associated to three fuzzy sets: a) antecedent: input *batch time* – early (ET), excellent (XT) and late (LT); input *carbon dioxide concentration in the effluent gas (molar fraction)* – low (LC), medium (MC) and high (HC) and input *carbon dioxide concentration derivate* – negative (DCN) and zero or positive (DCZP); b) consequent: no-stop cultivation (NS), attention (AT) and stop cultivation (S). The Table 1 shows the fuzzy logic rules implemented in this algorithm.

Table 1 – Fuzzy set rules of input and output variables.

Rules	IF (antecedent)	THEN (consequent)
1	ET **AND** LC **AND** DCN	NS
2	ET **AND** LC **AND** DCZP	NS

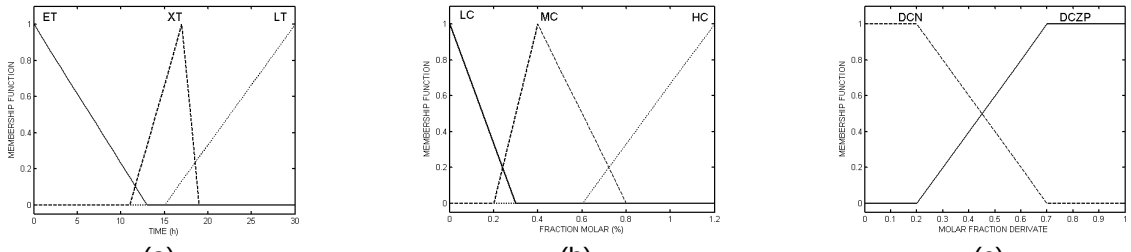
12	LT **AND** HC **AND** DCZP	NS
13	LT **AND** MC **AND** DCZP	NS

4 Results and Discussion

During the PGA production process several experimental condition were tested with the aim of obtaining a high enzyme concentration. At the same time, a fuzzy logic algorithm was developed. The data were composed by ten experiments, and this set was split in two: fuzzy parameters tuning (Runs 1-5) and validation of the algorithm (Runs6-10).
The best results were obtained using triangular and trapezoidal membership functions, as illustrate in Figures 1 and 2.



(a) (b) (c)

Figure 1. Final membership functions of antecedent part after parameters tuning: (a) Batch time; (b) molar fraction of CO_2; (c) derivate of CO_2molar fraction.

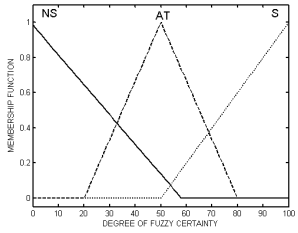


Figure 2. Final membership functions of consequent part (fuzzy certainty) after parameters tuning.

A sumary of the experimental data set used in this work, and the most important experimental results are shown in Table 2 and 3, respectively.

Table 2 – Experimental data set.

Assays	Operation Way	Stirrer speed control	Dissolved oxygen control (% sat.)	Experimental Initial pH	Feed
1	Batch	-	20%	8.0	-
2	Batch	-	20% and 5% after 8 h	8.0	-
3	Batch	-	10%	8.0	-
4	Batch	ISS*	-	8.0	-
5	Batch	-	0.5%	9.0	-
6	Batch	-	0.5%	8.0	-
7	Fed-batch	ISS	-	8.0	F=180 mL.h^{-1}; AA and CW (8h)
8	Batch	-	10%	8.0	-
9	Fed-batch	-	20% and 5% after 12 h	8.0	F = 30 mL.h^{-1} PAA (12 h)
10	Batch	ISS	-	8.0	

*ISS = Increasing stirrer speed (~20% saturação); F = feed flow; AA = mixture of amino acids (10 g.L^{-1}); CW = Cheese whey solution (19.6 g.L^{-1}); PAA = phenyl acetic acid (16.0 g.L^{-1}).

The best result was obtained when the dissolved oxygen concentration was maintained close to 0.5% of saturation between five and eighteen hours of culture (Runs 5-6). De Leon et al. (2003) obtained similar results during PGA producion process by *E. coli* .The dissolved oxygen concentration was maintained at 0.3 % of saturation.

Table 3 - Results of cell concentration, enzyme activity, fuzzy degrees and optimal time interval during penicillin G acylase production process by *Bacills megaterium*.

Assays	Cell Concentration (g.L^{-1})	Enzyme Activity (UI.L^{-1})	Degree of Fuzzy Certainty (%)	Optimal interval to stop the cultivation (h)
1	4.6±0.5	283± 5	81 % (12 h)	12 – 14
2	4.1±0.4	284± 4	82 % (16 h)	15 – 17
3	4.2±0.3	297± 4	80 % (14 h)	14 – 16
4	3.6±0.3	275±13	81 % (15 h)	16 – 18
5	4.5±0.3	532±13	80 % (16 h)	16 – 18
6	4.0±0.4	535±14	80 % (14 h)	15 – 16
7	4.6±0.3	275± 3	85 % (16 h)	18 – 20
8	4.9±0.3	346±10	81 % (12 h)	12 – 13
9	4.5±0.3	143±10	81 % (18 h)	17 – 20
10	4.1±0.2	240± 6	83 % (16 h)	16 – 18

The algorithm identifies one time interval to finish the cultivation, which was compared with the experimental region of maximum enzyme activity. It can be seen (Figure 3) that the fuzzy algorithm could successfully infer the region of maximum enzyme concentrations.

In Run-1 the interval 11.0 and 13.0 hr was determined by the algorithm as the end time with more than 81% degree of Fuzzy certainty (Figure 3a). Laboratory analyses showed that maximum enzyme activity was achieved at 14.0 hr (283± 5 IU.L^{-1}). In Run-2 the end of cultivation was defined by the fuzzy algorithm around 14.5 and 17.0 hr (82% fuzzy certainty), Figure 3b. The experimental maximum activity (284± 4 IU.L^{-1}) occurred in 16.0 hr. For Runs-3 and 4 (Figure 3c-d), the fuzzy algorithm indicated the end of the cultivation in 13.0 and 18.0 hr, respectively (80 and 81% fuzzy certainty). Maximum activity obtained was 297± 4 IU.L^{-1} (Run-3) and 275± 13 (Run-4). The results obtained during the adjust parameters showed that the Fuzzy algorithm was able to indicate the end of the experiments with good precision.

Five validation experiments were used to test the robustness and efficiency of the algorithm. The validation of the algorithm was done after running the inference on-line and identifying the end of cultivation (fuzzy certainty) at the time intervals shown in Figure 4. Nevertheless, the runs continued up to approximately 24 hr to provide extra data that would confirm the adequacy of the fuzzy inference. Of course, an actual industrial reactor should start harvesting when the maximum enzyme activity was reached. The fuzzy algorithm was successful in its predictions, providing time estimations of maximum enzyme activity within the correct experimental time span.

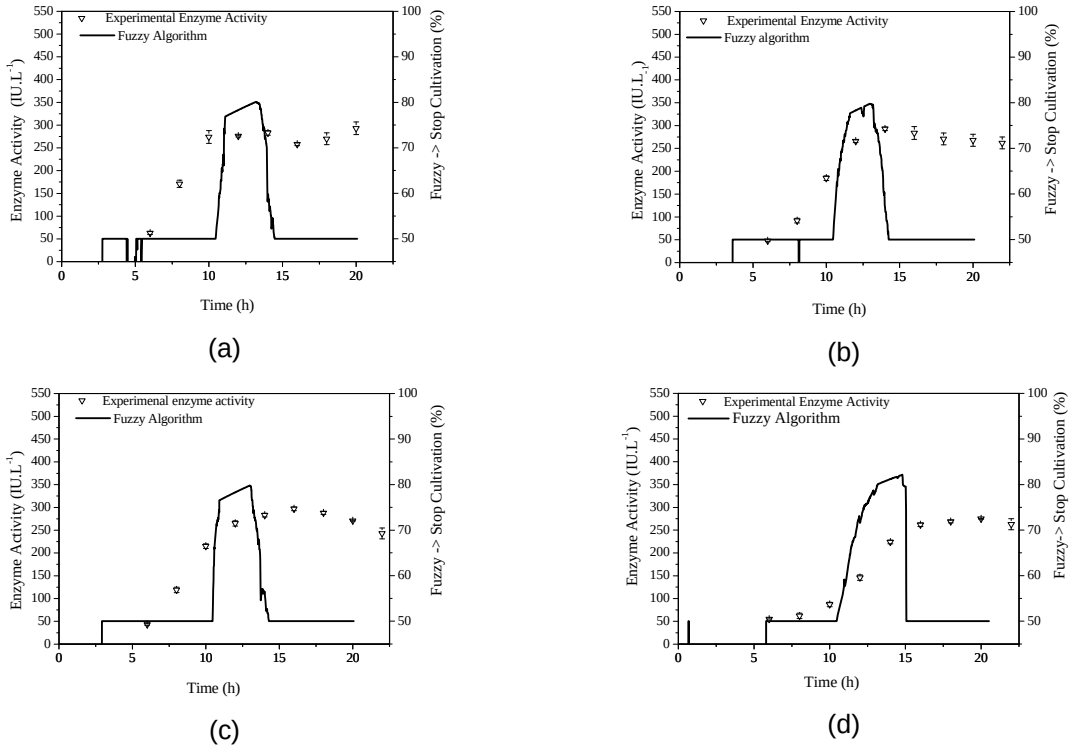

Figure 3. Training data set for tuning the fuzzy algorithm: (a) Run-1; (b) Run-2; (c) Run-3 and (d) Run 4. Bar errors standard deviations of triplicates.

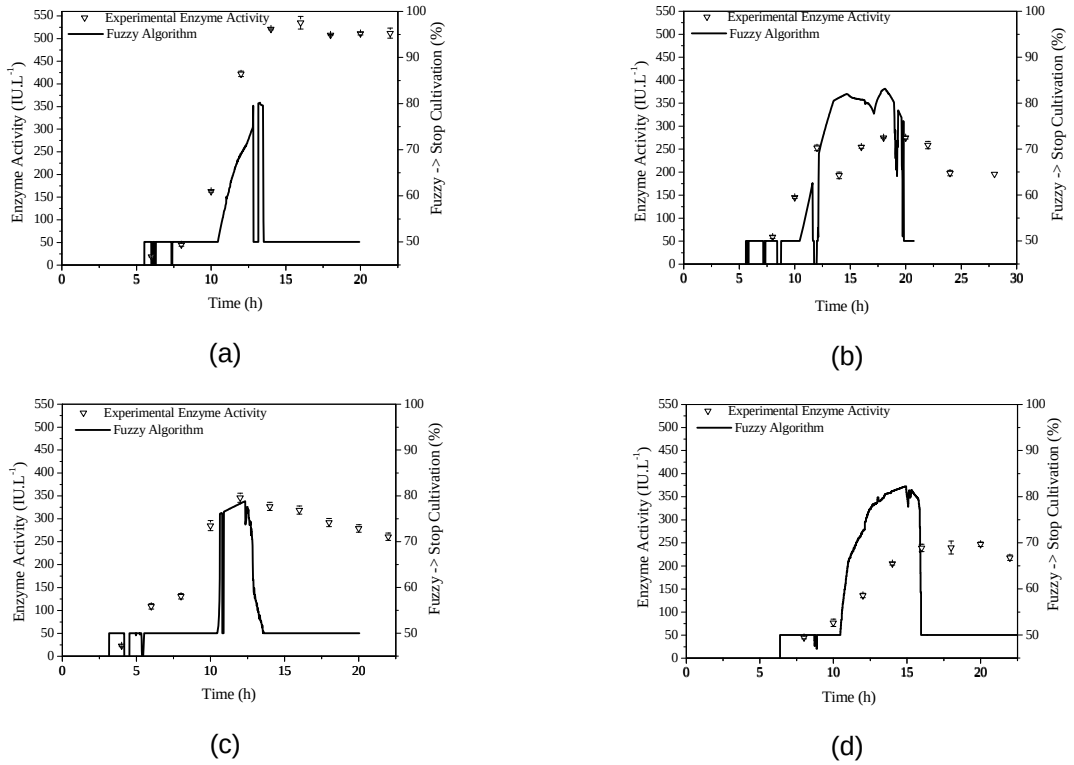

Figure 4. Validation of the fuzzy algorithm: (a) Run-6, estimated stop time with 80% of fuzzy certainty (between 12.8 and 14 hr), maximum experimental enzyme activity 16 hr (535±14 $IU.L^{-1}$); (b) Run-7, estimated stop time with 85% fuzzy certainty between 13 and 18 hr, maximum experimental enzyme activity 18.0 hr (275± 3 $IU.L^{-1}$); (c) Run-8, estimated stop time between 11.0 and 12.5 hr (81% fuzzy certainty), maximum experimental enzyme activity 12.0 hr (346±10 $IU.L^{-1}$) and (d) Run-10, estimated stop time between 11.0 and 16.0 hr (83% fuzzy certainty), maximum experimental enzyme activity 16.0 hr (240± 6 $IU.L^{-1}$). Bar errors: standard deviations of triplicate measurements.

5 Conclusion

The fuzzy logic algorithm developed in this work employs a simple model based on the Mandani inference method. It can be seen that the fuzzy algorithm could succesfully establish the region of maximum enzyme concentration, when harvesting should start, with values above eighty percent in all cases. The best experimental result during the PGA production process was obtained when the dissolved oxygen concentration was maintained close to 0.5% of saturation between five and eighteen hours of culture (Runs 5-6).

Topic: Stability testing of new Drug Substances

Abstract

FDA stability guidance document stipulates that an API should be subjected to a number of forced degradation and stress conditions. The current International Conference on Harmonization (ICH) guidances (Q2A and Q2B) do not specify how degradation studies are to be conducted; this was left to the discretion of the responsible companies.

Forced degradation should be one of the activities performed early in the development process to ensure that the method is discriminating before a lot of time, effort and money have been expended. The guidance documents do not indicate detailed conditions, so the conditions and interpretations are left up to the team who work in the field.

Trial and error are needed to find the proper combination of stress agent concentration and time to effect degradation, preferably in the 20-30% range. Depending on the API, not every stress agent may effect degradation, but each agent has to be evaluated to determine whether degradation results.

Here we described the decomposition of an active pharmaceutical ingredient (API) under hydrolytic (acidic, alkaline), oxidative, dry heat and photolytic conditions.

1 Introduction

In order to achieve a high level of safety and effectiveness of pharmacotherapy the requirements on quality of active substance are growing[1,2]. The Investigation of stability of drugs represents an important issue in drug quality evaluation. Many environmental conditions, for example heat, light, humidity as well as substance ability for hydrolysis or oxidation can play an important role in drug stability. Stress testing[3] of a drug substance can help identify the degradation products and provide important information about the inherent stability of the drug substance under hydrolytic, oxidative and photolytic conditions. Moreover, during a stress study the suitability of the proposed analytical procedure to control the purity of samples may be verified.

The HPLC method described in European Pharmacopoeia[4] were used to monitor and identify the degradation products.

2 Experimental

2.1 Chemicals and Reagents

Active pharmaceutical ingredient working standard power was supplied by CIPAN S.A. Sodium hydroxide, hydrochloric acid, hydrogen peroxide, sodium dihydrogen, phosphoric acid and all used solvents of HPLC grade were purchased from Merck (Darmstadt, Germany). Purified HPLC grade water was obtained by reverse osmosis and filtration through a Milli-Q® system (Millipore, Milford, MA, USA) and was used to prepare all solutions.

2.2 HPLC instrumentation and conditions

Chromatographic experiments were performed using a Waters chromatograph 2695 separations module equipped with a Photodiode array detector Model 2996.

The column used was: 100mmx4.6mm I.D. Hypersil ODS with 5µm particle.

The mobile phase was prepared as follows:

mobile phase A: a 7.8g/l solution of sodium dihydrogen phosphate adjusted to pH 4.0 with phosphoric acid.

mobile phase B: a mixture of equal volumes of mobile phase A and methanol HPLC

Time (min)	Mobile phase A (per cent V/V)	Mobile phase B (per cent V/V)
0-4	100	0
4-15	100→50	0→50
15-18	50	50
18-24	50→100	50→0
24-39	100	0

The mobile phases were filtered through a 0.2µm filters and degassed under vacuum prior to use. The flow rate was 1.0ml/min. The column was maintained at 40ºC and an injection volume of 20µl was used.

The HPLC method was employed to study decomposition of API in reaction mixtures. The blank consists in mobile phase A.

For analysis of forced degradation samples, the photodiode array detector was used in scan mode with a scan range of 210-600nm. Peak homogeneity was expressed in terms of peak purity values, and was obtained directly from spectral analysis report obtained using the instrument software.

2.3 Sample preparation

Solutions of API (10mg/ml) were prepared by accurately weighing approximately 100mg of API into 10ml A-grade volumetric flask and making up to volume with mobile phase A. The solution has to be prepared immediately before use.

2.4 Forced degradation studies of API

All stress tests were carried out on a single batch of API. All solutions prepared for use in forced degradation studies were prepared to yield starting concentrations of API of 10mg/ml.

2.4.1 Oxidative studies

Solution for oxidation study was prepared in 3% H_2O_2, protected from light and stored at room temperature for 10 minutes.

2.4.2 Acid degradation studies

Solution for acid degradation study was prepared in 0.01M hydrochloric acid, protected from light and stored at room temperature for 30 minutes.

2.4.3 Alkali degradation studies

Solution for alkali degradation study was prepared in 0.01M sodium hydroxide, protected from light and stored at room temperature for 10 minutes.

2.4.4 Temperature stress studies

Susceptibility of the drug to dry heat was studied by exposing the drug to 60ºC for 5 days.

2.4.5 Photostability studies

API powder was spread on a glass dish and exposed to light for 9 days resulting in overall illumination of 200wh/m^2 with UV radiation at 360nm.

3 Results and discussion

In order to determine whether the analytical method was stability-indicating, API powder was stressed under various conditions to conducted forced degradation studies. Regulatory guidance ICH Q2A, Q3B and FDA 21 CFR section 211 all require the development and validation of stability indicating potency assays. Unfortunately, the current guidance documents do not indicate detailed degradation conditions in stress testing. However, the used forced degradation conditions, stress agent concentration and times of stress, were found to effect degradation, preferably not less than 10% and not complete degradation of active materials. The discovery of such conditions was based on trial and error.

The chromatogram of the starting sample of Bulk API taken to the stress tests is presented in Fig. 1.

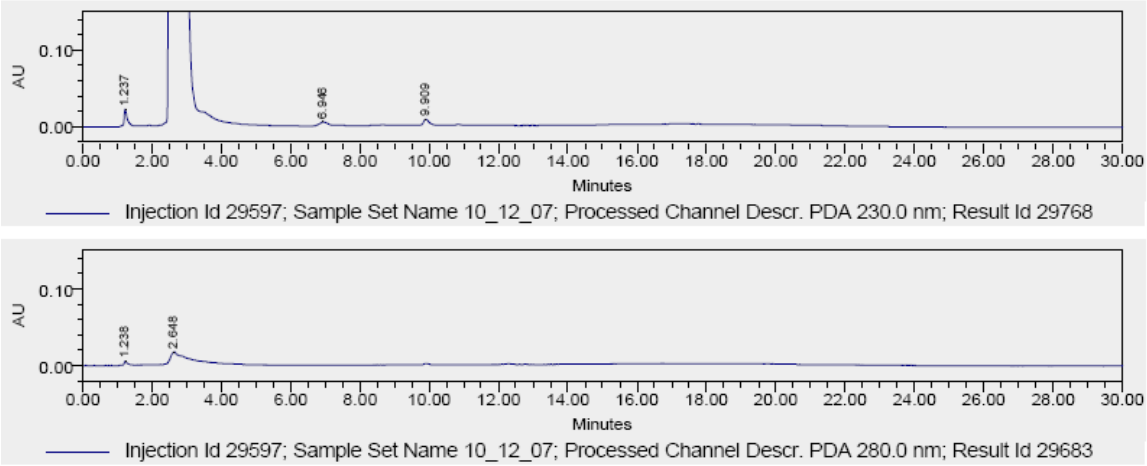

Figure 1- Chromatogram of bulk API before stress test at 230nm and 280nm

Under the dry heat (even after exposure to 60ºC for 5 days) and after 9 days of UV light exposure the samples were found to be stable (fig. 2 and fig.3).

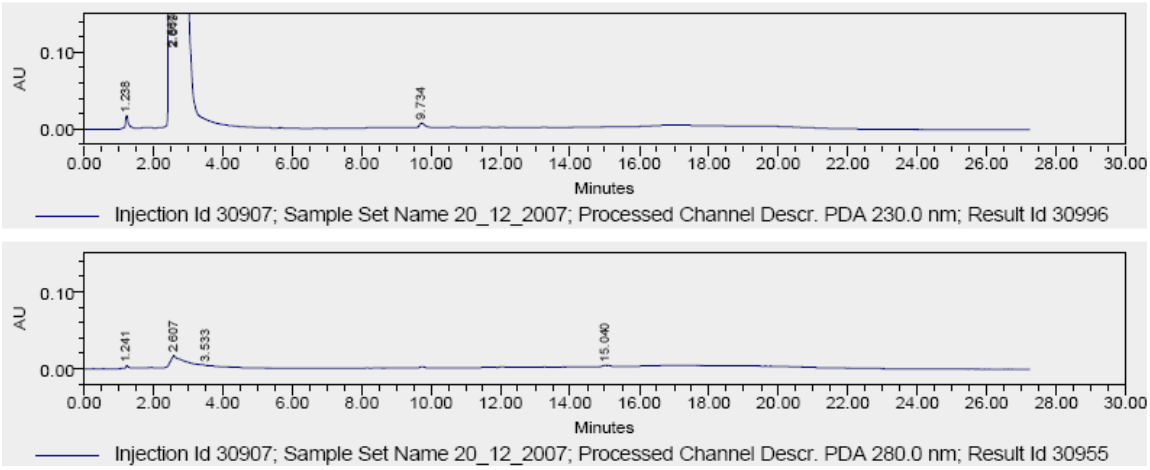

Figure 2- Chromatogram of sample subjected to dry heat (60ºC, 5 days) at 230nm and 280nm

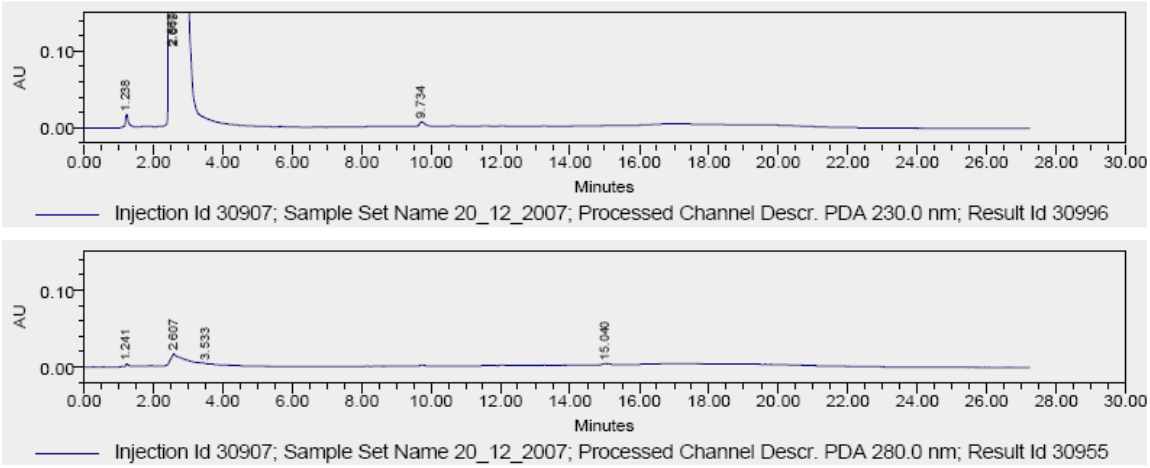

Figure 3- Chromatogram of sample subjected to UV light (9 days) at 230nm and 280nm

The studies under acidic and basic conditions shown that bulk API seemed to be really sensitive to pH variation (fig. 4 and Fig 5).

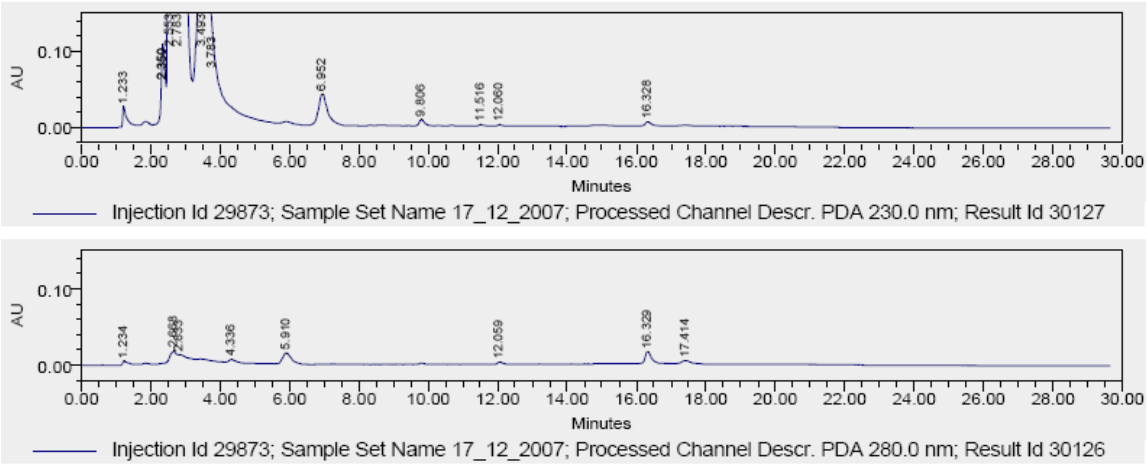

Figure 4- Chromatogram of sample subjected to 0.01M hydrochloric acid (30 min) at 230nm and 280nm

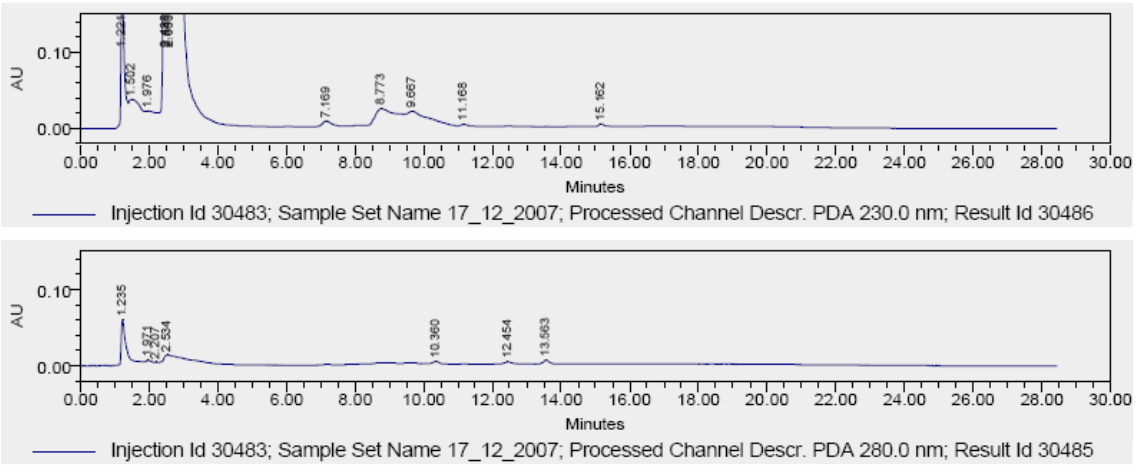

Figure 5- Chromatogram of sample subjected to 0.01M sodium hydroxide (10min) at 230nm and 280nm

Bulk API was very instable in 3% hydrogen peroxide at room temperature after 10minutes almost 50% of API was disappeared (figure 6).

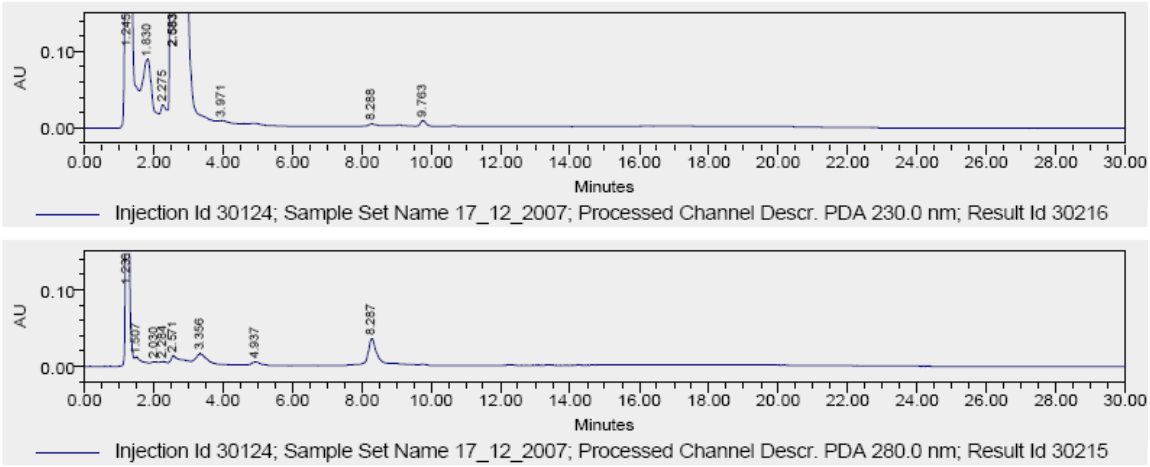

Figure 6- Chromatogram of sample subjected to 3% H_2O_2 (10min) at 230nm and 280nm

4 Conclusions

The results of stress tests undertaken according to the ICH guidelines reveal that the method is selective and stability-indicating. The proposed method is simple and has the ability to separate the drug from degradation products. The method is suitable for the routine analysis of bulk API powder. The simplicity of the method allows for application in laboratories that lack sophisticated analytical instruments, such as LC-MS or GC-MS. These methods are complex, time consuming and more costly than a simple HPLC-UV method. In addition, the HPLC procedure can be applied to the analysis of samples obtained during accelerated stability experiments to predict expiry dates of pharmaceuticals.

Keywords: FT-IR Spectroscopy, Multivariate Analysis, Microbiology
Topic: Systematic methods and tools for managing the complexity

Abstract

Clinical microbiology deals with the laboratory diagnosis of infectious diseases trying to elucidate spreading routes of given bacterial strains and further characterise the microbial species and their resistance to antimicrobial agents. Most clinical laboratories rely on the phenotype-based or molecularly oriented methods for straightforward microbial typing at the different taxonomic levels. Although precise, these methods are expensive, time consuming, and they require a highly trained staff, which limits their applicability on the routine basis.

The Fourier transform infrared (FT-IR) spectroscopy has been by now successfully applied for rapid, accurate and cost-effective identification of pathogenic microorganisms. It is considered to be a powerful and versatile technique in microbiology that can assess the overall molecular composition (spectral fingerprints) of microbial cells in a non-destructive manner. Still a major concern in using FT-IR for pathogens discrimination are spectral pre-processing procedures and their impact on the increase of chemometrics models robustness. A hierarchical classification strategy together with unsupervised and supervised (Principal Component Analysis – PCA, Partial Least Squares - PLS) pattern recognition methods was used for the discrimination. Since selection of discriminative spectral regions is a critical step in calibration model development, different variable selection methods (genetic algorithm, PLS-bootstrap) have been tested as well.

Here the general contribution of FT-IR spectroscopy and chemometrics to pathogenic microorganisms' discrimination at different taxonomic levels will be discussed. Analysis of *Acinetobacter baumanni*, *Enterococcus faecium* and *Staphylococcus aureus* isolates showed clear separation within the genus level. Closely related *Salmonella enterica* serotypes (Enteritidis, Typhimurium, Bredeney, Goldcoast, Rissen, Hadar, Derby, Essen, Virchow, Mbandaka, Menden, Agona, Brikama, Saintpaul, Anatum, Infantis, Braenderup, Mikawasima) examined by FT-IR spectroscopy and chemometrics demonstrated the possibility of correct differentiation at the serotype level. Our latest results show as well that there is a considerable potential to effectively fulfil the current requirements for rapid and correct differentiation of *Salmonella* Enteritidis phage types.

* bsel@ist.utl.pt

1 Introduction

Because of the increasing prevalence of infectious diseases, there is a continuing requirement for accurate, rapid, and reliable methods for the discrimination among a wide range of clinically relevant pathogenic microorganisms.

Vibrational spectroscopic techniques, namely Fourier transform infrared (FT-IR) and Raman spectroscopy, have been used since the 1980s as complementary methods for bacteria differentiation owing to their rapid 'fingerprinting' capabilities and the molecular information that they can provide [1–3]. FT-IR spectra comprise the vibrational characters of all cell constituents, that is, DNA/RNA, protein, membrane and cell-wall components. Figure1 depicts typical raw bacterial FT-IR spectra.

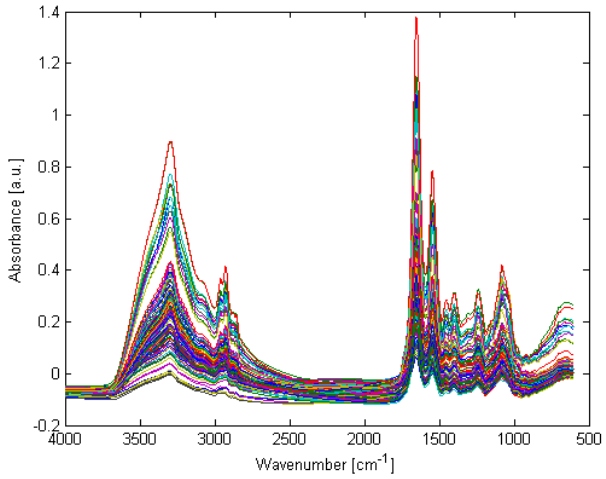

Figure1. Observed FT-IR raw spectra collected for *Acinetobacter baumanni*, vancomicin-teicoplanin resistant *Enterococcus faecium* (VRE), and meticillin resistant *Staphylococcus aureus/epidermidis* (MRSA)

FT-IR spectroscopy generates large amounts of data, hence requiring appropriate multivariate statistical methods depending on the specific objective. We have applied both supervised and unsupervised techniques in order to represent the information from hyper-spectral data, namely Principal component Analysis (PCA), Partial Least Squares regression (PLS), Partial Least Squares Discriminant Analysis (PLSDA) among others. With the purpose of optimizing the discrimination between diverse microbial species and strains on a routine basis, we analyzed different spectra pre-processing methods and assessed their impact on spectral variability, model complexity reduction (e.g., number of latent variables), and influence on model robustness.

2 Experimental

2.1 Phenotypic typing (FT-IR)

The strains were cultured in tryptose soya agar (TSA), 24 h at 37°C. Thirty five microliter aliquots of the bacterial suspensions were evenly applied onto each well in a plate. Prior to analysis the samples were over dried at 44°C for 40 min. Samples were run in replicate and analyzed by FT-IR spectroscopy using a TENSOR spectrometer (Bruker Optik GmbH) in transmittance mode. Spectra were collected over the wavenumber range of 4,000 cm^{-1} to 600 cm^{-1} under the control of a personal computer using OPUS 5.0 software. Spectra (see Figure1) were displayed in terms of absorbance as a function of the wavenumber (cm^{-1}).

2.2 Data analysis and calibration development

The quality of each spectrum was evaluated using a quality test in the OPUS 5.0 software. All calculations were carried out using Matlab version 6.5 release 13 (MathWorks, Natick, MA) and the PLS Toolbox version 3.5 for Matlab (Eigenvector Research, Manson, WA). Savitzky-Golay derivatives, multiplicative scatter correction (MSC), extended multiplicative scatter correction (EMSC), and standard normal variate (SNV) were applied to the spectra and compared.

3 Results and discussion

3.1 Discrimination of pathogenic microorganisms within the genus level

A total of 105 isolates of multiresistant *Acinetobacter baumanni*, vancomicin-teicoplanin resistant *Enterococcus faecium* (VRE), and meticillin resistant *Staphylococcus aureus/epidermidis* (MRSA) from two Portuguese Hospitals during the years 2004 to 2007 were analyzed. Strains were isolated from feces, catheters, perianal swab, urine, respiratory samples, pus, blood and pleural fluid. Isolates were evaluated by infrared spectroscopy. Simultaneous molecular typing was performed with the use of PFGE (Pulse Field Gel Electrophoresis).

By viewing the PCA score plots of the first two latent variables (Figure 2), it is possible to observe three non-overlapping clusters corresponding to known strain types under investigation. Group of *Staphylococcus* shows clear division between *Staphylococcus aureus* (bigger cluster) and *Staphylococcus epidermidis* (smaller cluster). Obtained results demonstrate concordance with simultaneous classification obtained with use of PFGE typing.

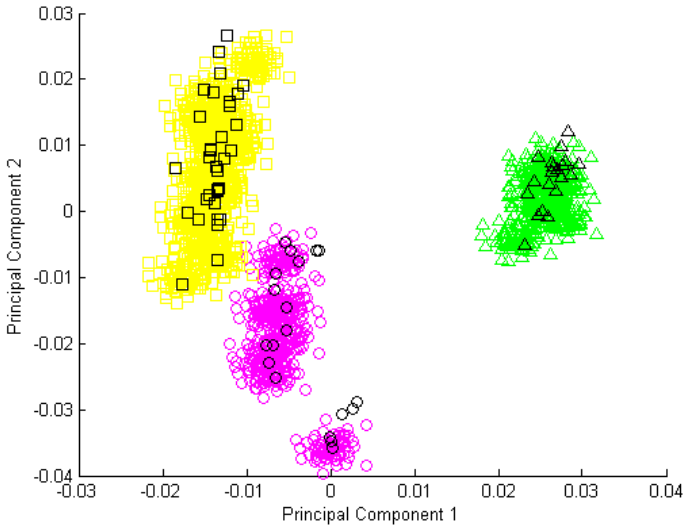

Figure2. Score plot mapping the first against the second principal components of PCA. Scores are represented with markers (□ — *Acinetobacter baumani*, ○ — *Staphylococcus aureus/Staphylococcus epidermidis*, Δ — *Enterococcus faecium*). 95% confidence limits for each group.

3.2 Discrimination of pathogenic microorganisms at the serotype level

A total of 148 isolates of closely related *Salmonella enterica* serotypes (Enteritidis, Typhimurium, Bredeney, Goldcoast, Rissen, Hadar, Derby, Essen, Virchow, Mbandaka, Menden, Agona, Brikama, Saintpaul, Anatum, Infantis, Braenderup, Mikawasima) examined by FT-IR spectroscopy and chemometrics demonstrated the possibility of correct differentiation at the serotype level. The analysed *Salmonella* strains were obtained from the Portuguese Salmonella Reference Laboratory collection and have clinical and food origin. Simultaneous serotyping analysis was performed and classification was deduced from the specific pattern of agglutination reactions using the Kauffmann-White classification scheme that lists antigenic formulas of *Salmonella*.

Figure3 shows a clear distinction of serotypes representing the *Salmonella enterica* serogroup B: *Salmonella* Typhimurium, *Salmonella* Bredeney, *Salmonella* Saintpaul, and *Salmonella* Heidelberg. Obtained results demonstrate concordance with simultaneous classification obtained by serotyping.

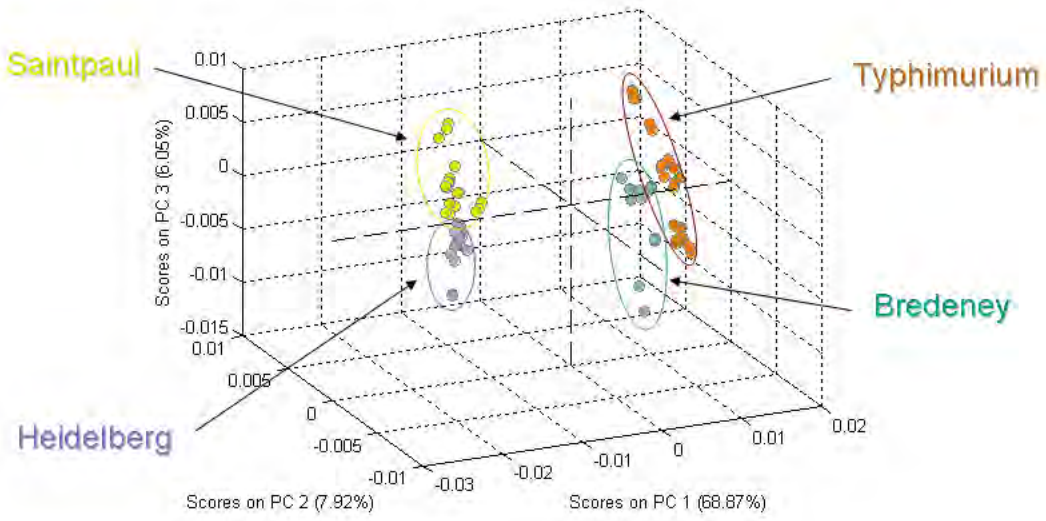

Figure3. Score plot mapping the three first principal components of PCA for analysis of *Salmonella* Typhimurium, *Salmonella* Bredeney, *Salmonella* Saintpaul, and *Salmonella* Heidelberg.

4 Conclusions

The aim of our study was to differentiate selected pathogenic microorganisms at different taxonomic levels. We have analyzed and optimized different spectra pre-processing methods and their impact on the reduction of spectral variability and on the increased robustness of chemometrics models. Fourier Transform Infrared Spectroscopy together with chemometric techniques have shown considerable potential to effectively fulfil the current requirements for fast and correct differentiation of bacteria.

Keywords: Risk quantification, aseptic processes, microbiological contamination, quality by design, pharmaceutical industry.
Topic: Risk quantification tool to perform a rational integration of information regarding Microbiological contamination.

Abstract

Being the sterility assurance of products based on the conformity of all the manufacturing process parameters – Quality by Design, it's essential to have a way of measuring the impact of the different manufacturing scenarios on the global microbiological risk.

Here we report on a risk quantification tool that allows the rational integration of the available information regarding microbiological contamination of aseptic processes.

This tool is based on a mathematical model appropriate to quantify situations involving multiple criteria. The success of its implementation depends on the correct identification of the critical points and the cooperation of people with solid process understanding.

Although the work presented emphasizes the process characterization, like the enhancement of possible worst-case manufacturing scenarios, other applications can be considered, like the support of batch release decisions or as a PAT tool, since it's possible to use in it real time data.

A discussion of all these aspects will be made based on the experience obtained in developing and applying this toll in a sterile production facility.

1 Introduction

The most critical issue when dealing with aseptic processes is the contamination control. Evaluation of the contamination risk involves the analysis of several parameters known to have possible impact on the sterility of products. This means that an investigation of a microbiological contamination event involves a detailed review of all the available information about the process in order to help evaluating the situation and to support decisions (EC GMP, 2008).

Understanding the meaning of the data available is a major concern and not always easy to accomplish since the data is not easy to read or to relate and does not give obvious answers. The location of a contamination detected, the number of colonies forming units (c.f.u.) involved, and the type of microrganisms (m.o.) identified are parameters always considered when evaluating the contamination risk to a sterile product. It is easy to recognize that contamination detected inside a Class A environment, where sterile product is exposed,

* bsel@ist.utl.pt

points to a more critical situation concerning product sterility then a contamination detected in auxiliary areas. Nevertheless there are other facts also important to take into consideration when evaluating contamination risk since they can influence the meaning of the data available. The skills of the operators engaged on the process, the number of people involved, results from risk assessment of the aseptic process, specific conditions of the production line, are important information that even unconsciously is taken into consideration by someone with deep process knowledge when reviewing the data.

Even considering all the factors involved in a certain process it is difficult to make a rational integration of all that information, especially when dealing with larger quantities of factors and factors with different weighs. The case study presented is an approach to do a rational integration of different factors when evaluating risk contamination of aseptic processes. This was achieved using a tool based on a mathematical model – Analytic Hierarchy Process (AHP) – appropriate to quantify situations involving multiple criteria. The use of a quantification method was considered useful in order to allow easily characterizing each situation regarding contamination risk in a comparable way.

The AHP is a decision support method, in which a complex problem is broken into a simple hierarchy structure of constituent elements, where weights are determined by pairwise comparisons (Douligeris et al, 1994; Fogliatto et al, 2003; Vila et al, 1995). The success of its implementation depends on the correct identification of the critical points and the cooperation of people with solid process understanding.

1.1 Analytical Hierarchy Priority - AHP

The Analytic Hierarchy Process is a decision support method, in which a complex problem is broken into a simple hierarchy structure of constituent elements, where weights are determined by pairwise comparisons (Douligeris et al, 1994; Fogliatto et al, 2003; Vila et al, 1995).

The steps to follow while implementing the AHP process are:

1 – Set up a decision hierarchy;
2 – Collect input data by pairwise comparisons of decision elements;
3 – Assessment of the consistency of the decisions taken – consistency ratio;
4 – Determination of the relative weights of the components of decision.

Decision Hierarchy

A decision hierarchy is set up by breaking down the problem into a hierarchy of interrelated decision elements – criteria and alternatives. The overall goal is placed at the top, with the remaining attributes on levels bellow (See Figure 1).

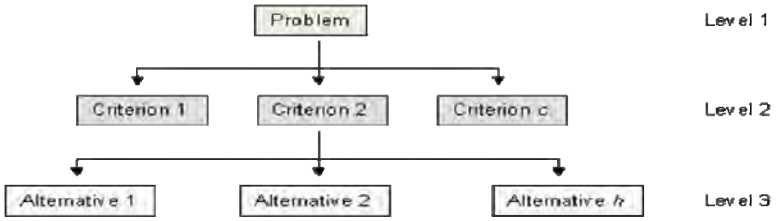

Figure 1 – Hierarchical scheme of a decision problem (Vila et al, 1995).

Pairwise Comparisons of Decision elements

The input data is generated by comparing all pairs of elements in one level with respect to one element in the previous adjacent level. The resulting comparisons are organized in comparison matrices n x n, where n represents the number of alternatives in each level and the order of the matrix (See Table 1). Each entry of the matrix (aij) corresponds to the pairwise comparison, showing the strength of element i in comparison with element j (Vila et al, 1995).

Table 1 – General comparison matrix (Vila et al, 1995).

	1	2	…	N
1	1	A12	…	A1N
2	A21	1	…	A2N
…	…	…	…	…
N	aN1	aN2	…	1

The pairwise comparison is quantified according to its importance for the decision element or team, which is based on a 1 to 9 scale – Saaty's scale (Fogliatto et al, 2003).

An element is equally more important when compared to itself, thus the main diagonal of a comparison matrix must consist of 1's. Comparison of element B with element A is the reciprocal of the comparison between element A and B, i.e. aBA = 1 / aAB (Fogliatto et al, 2003).

To analyze the problem in Figure 1, c+1 comparison matrices must be generated: c matrices comparing the alternatives in Level 3 with respect to each criterion in Level 2, and one matrix comparing the criteria in Level 2 with the problem statement in Level 1 (Fogliatto et al, 2003; Vila et al, 1995).

Assessment of the consistency of the decisions taken

In order to consider the decisions taken by the decision elements valid and consistent, it is necessary that the consistency ratio (CR – ratio between the constancy index (CI) and a random consistency index (RI)) correspondent to each matrix obeys to the following statement (Equation 1):

Equation 1 - Calculation of the CR.

$$CR = \frac{CI}{RI} = \frac{(\lambda_{máx} - n) \diagup (n-1)}{RI} \leq 0{,}10$$

Where n is the order of the matrix, and λmáx is the largest or principal "eigenvalue" of the comparison matrix, which can be shown to satisfy λmáx ≥ n.

The consistency index (CI) gives an indication of the accuracy of the method. The consistency index of a randomly generated reciprocal matrix from the scale 1 to 9, with reciprocal forced, is called the Random Index (RI), and it was proven that it has typical values.

Determination of the relative weights of the components of decision

To estimate the vector of priorities (VP), sum the elements in each row of the comparison matrix and normalize this sum by dividing it by the total of sums. The results of all sums should add up to unity (Fogliatto et al, 2003).

The final purpose of AHP is to aggregate the relative weights of decision elements to arrive to a final score for each option, adjusting the scores reflecting the weight given to the criteria with the score reflecting the weight of each alternative, as it is shown in Equation 2 (Fogliatto et al, 2003).

Equation 2 - Calculation of relative weights.

Problem = [VP(Criteria 1) x VP(Combined alternative)] +

[VP(Criteria 2) x VP(Combined alternative)] +

[VP(Criteria c) x VP(Combined alternative)]

2 Case Study

The key steps were the construction of the decision hierarchy, identifying the problem, the criteria and the alternatives.

2.1 Decision Hierarchy

The main purpose of this case study was to quantify each possible situation regarding contamination risk that could happen in the aseptic processing areas (APA) under study. The first step of the process was to identify the data available and other information that could influence the meaning of the data available even in a minor way, and adapt it to a format that allowed the application of the method. This was a critical part of the process since it was where all the variables we wanted to consider were structured.
The decision hierarchy obtained is represented on Figure 2.

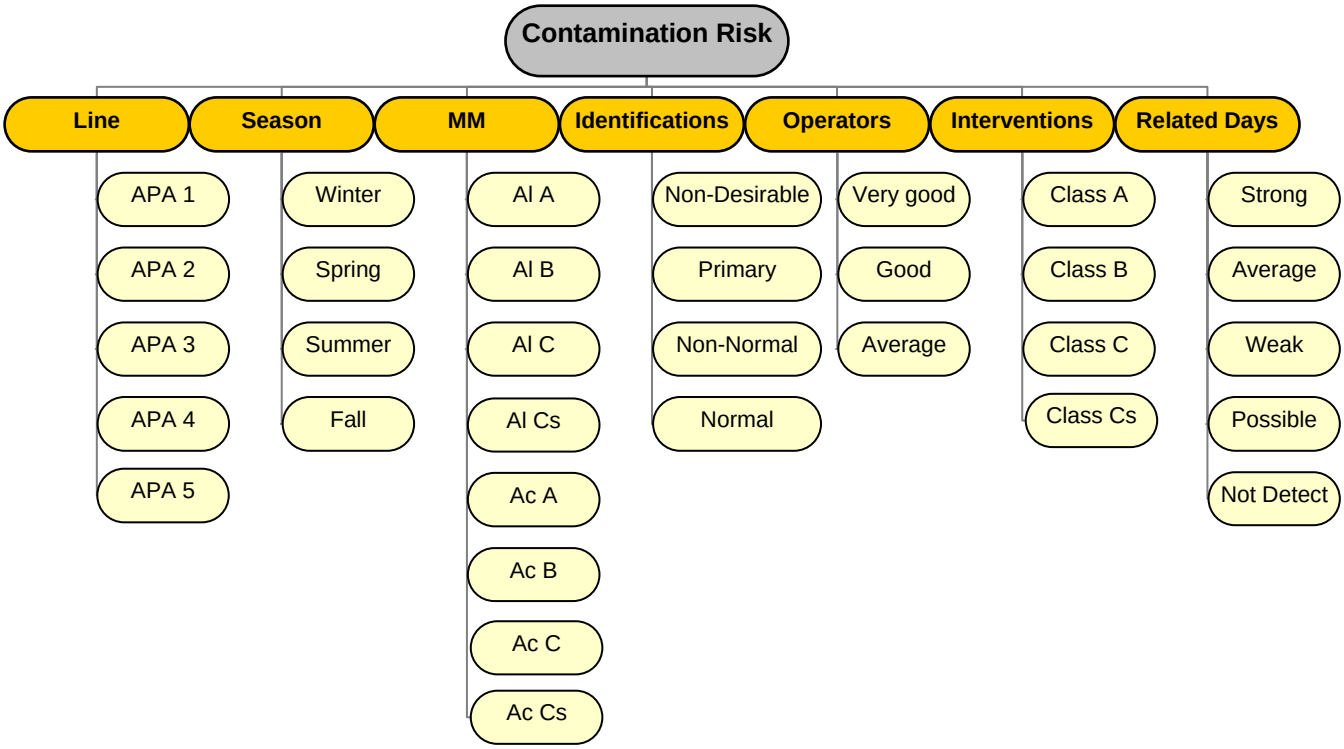

Figure 2 - Hierarchical scheme related to the problem in study - contamination risk of sterile products.

2.2 Pairwise Comparisons of Decision elements

The comparison between the criteria and alternatives was done through the construction of matrices where all the elements were compared with each other in what concerned to their impact on the contamination risk. The comparison between criteria and an example of comparison between alternatives are present next.

Table 2 - Global matrix: comparison between criteria concerning the problem.

	PL	S	MM	ID	OP	IT	RD	PV
Production Line (LP)	1	5	1/5	1/3	1	1/5	1/3	0,077
Season (S)	1/5	1	1/9	1/8	1/5	1/9	1/8	0,018

Microbiological Monitoring (MM)	5	9	1	3	5	1	3	0,256
Identifications (ID)	3	8	1/3	1	3	1/3	1	0,158
Operators (OP)	1	5	1/5	1/3	1	1/5	1/3	0,077
Interventions (IT)	5	9	1	3	5	1	3	0,256
Related Days (RD)	3	8	1/3	1	3	1/3	1	0,158
								1

Table 3 - Comparison matrix of the alternatives concerning identifications.

	ND	**PP**	**NNF**	**NF**	**PV**
Non-Desirable (ND)	1	5	7	9	0,589
Primary Pathogenic (PP)	1/5	1	3	5	0,247
Non-Normal Flora (NNF)	1/7	1/3	1	3	0,120
Normal Flora (NF)	1/9	1/5	1/3	1	0,044
					1

2.3 Assessment of the consistency of the decisions taken

The decision team was responsible for the scores given in all the matrices, using the Saaty's scale. The validation of these decisions was accomplished through the calculation of the consistency ratio (CR) concerning each matrix. All the matrices fulfilled the requisites to consider the decisions valid – $\lambda máx > n$ and $CR < 0,10$, being all the decisions taken by the decision team considered valid.

2.4. Determination of the relative weights of the components of decision

The calculations were made using Equation 2 regarding each combination of factors. Example on

Table 4 shows the combination of factors representing the worst case scenario concerning the contamination risk:

- Production line (0,077) – APA 4 or 5 (0,387)
- Season (0,018)- Winter (0,484)
- Microbiological monitoring (0,256) – Action level Class A (0,307)
- Identifications (0,158) – Non-desirable (0,589)
- Operators (0,077) – Average (0,696)
- Interventions (0,256) – Class A (0,589)
- Related days (0,158) – Strong (0,436)

Table 4 – Example of calculations and results for the worst case scenario.

RESULT	
(0,077 x 0,387) + (0,018 x 0,484) + (0,256 x 0,307) + (0,158 x 0,589) + (0,077 x 0,696) + (0,256 x 0,589) + (0,158 x 0,436) =	0,483

2.5. Results

Using this tool it is possible to characterize each process situation regarding contamination risk in a comparable way. Figure 3 is a chart constructed using data collected during one year from one of the production lines where is possible to view profound differences in the values obtained depending on the circumstances.

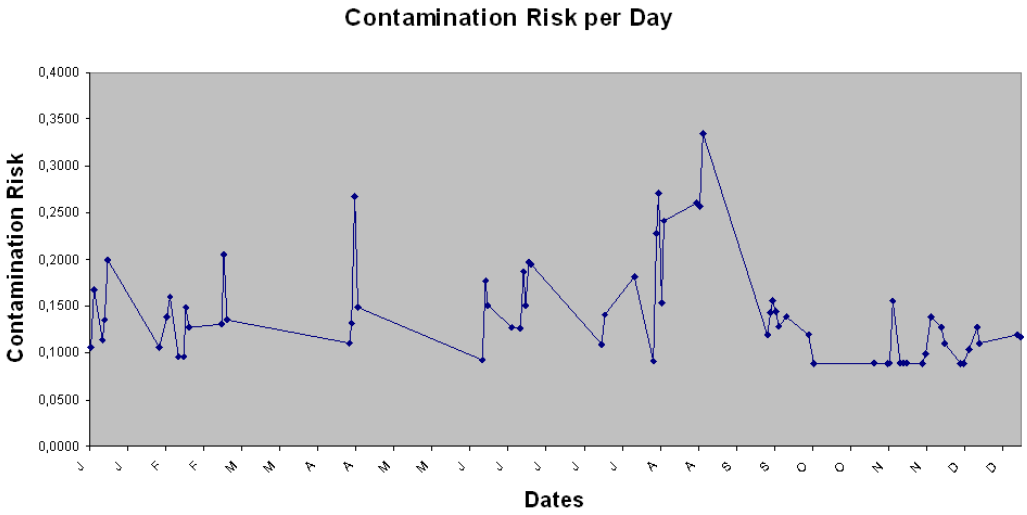

Figure 3 – Results of Contamination Risk per Day.

3. Conclusions

Contamination control is the major issue when dealing with aseptic processing. Evaluation of the contamination risk involves the analysis of several parameters known to have possible impact on the sterility of products. To take into consideration all the factors involved in a certain process it is important to make a rational integration of all that information.

The case study presented is an approach to do this rational integration of different factors that influence risk contamination of aseptic processes. This was achieved using a tool based on a mathematical model – Analytic Hierarchy Process (AHP) – appropriate to quantify situations involving multiple criteria.

Although the work presented emphasizes the process characterization using a specific type of available data, other applications can be considered, like the support of batch release decisions based on the risk level obtained, or as a PAT tool, since it's possible to apply this tool with real time data.

Novel method for accelerated analytical control of biological (bacteriological) agents

Valery P. Nesterenko*
Ecology Department, Belarusian National Technical University
65, Nezavisimosty Avenue, 220027, Minsk, Republic of Belarus

Keywords: biological pollution, analytical control, hard nutrient media, solid inorganic material.
Topic: Integration of life sciences & engineering.

The permanently rising biological pollution of the environment including the water objects requires organization of legible and operating scientific grounded control quality system concerning to such pollution in view of maintenance of a principle of epidemic safety. The solution of these problems with the purpose of the water-sources protection from biological pollutions, including the case of biological terrorism, is actual today and will be in future (Rosebury et al., 1947; Rosebury, 1949; Rożniatowski and Żółtowski, 1957).

One of the most important directions of scientific research in the field of studying and hygienic setting of biological pollution is the development of effective monitoring system. In its turn, the basic moment for monitoring implementation of the water-sources is developing and perfecting of indication methods of different kinds of biological contaminants including working out of accelerated methods of microorganism extraction from environment. And the success of antibacteriological protection in many respects depends on as far as the indication can be fast carried out (Rothschild, 1964; Hersh, 1969; Archangelsky et al., 1971).

The present work is devoted to creation of the accelerated microbiological analysis for environment monitoring including the water objects. Mainly, in the practice of modern microbiology at the estimation of environment quality the microbiological analyses are carried out by cultivating microorganisms on different hard nutrient media prepared by dissolution of nutrient materials and special solidifying matter (agar, gelatine, derivatives of cellulose, etc.) in water with the subsequent formation of gel (Meynell and Meynell, 1965). From known ways of preparing of hard nutrient media the way with usage of agar is the best. However, the process of preparing of this nutrient medium to an inoculation is characterized by large duration (3-5 hours) and complexity, including operation of sterilization for which, besides, the special equipment is necessary.

In this work the new approach to preparation of hard nutrient media is proposed, namely, – impregnation by solution of nutrient materials by a special way of the treated plates from solid inorganic materials. Applying such materials as a basis for hard microbiological nutrient media became possible after the capacity of different microorganisms for active growth and formation of colonies on a surface of such nutrient media was detected in which were used as a sealing basis specially prepared solid inorganic materials but not gel-forming matters. The plates prepared by the given way in sterile conditions are sealed in polyethylene packages where they can be stored a long time without loss of exploitative properties. The duration of preparation of such nutrient media directly to an inoculation equals 5-10 min. The specimens of different microorganism groups, actinomyces, streptococci, yeasty and mouldy fungi grow well on such media.

* Tel + 7 (495) 2411456. E-mail: v.nesterenko@mail.ru

Example 1. Round plates with a diameter of 90 mm and thickness 8 mm of a solid inorganic material with open pores of a specific size and hardness on a Moos's scale equal 6 were applied. The plates were impregnated with a liquid Czapek's medium and sterilized in autoclave under 175 kPa during 30 min, then dried up at the temperature of 353-363 K up to constant weight. The prepared plates in sterile conditions were put in packages of polyethylene sterilized by ethanol and packages were sealed.

Test of operation properties of a dry nutrient medium prepared by the given method was made as follows. The packages with plates stored for 72 hours were treated by ethanol and opened by sterile scissors. 20 plates were put by sterile tweezers in sterile Petri dishes by one plate into dish. Sterile distilled water was introduced into dishes and was swallowed by plates. The duration of preparation of a medium to inoculation equals 5-10 min.

In comparison a powder of a dry nutrient medium "Czapek's agar" was kept in distilled water for swelling within 1 hour, was dissolved under heating on boiling water bath, was sterilized in autoclave under 175 kPa during 30 min, poured out in 20 sterile Petri dishes and was kept under room temperature till solidification. The duration of preparation of a medium to inoculation equals 2-3 hours. In addition for a comparison dissolved, cooled sterile Czapek's medium, stored a flask, was melt down, poured out in 20 sterile Petri dishes and kept till solidification. The duration of preparation of a medium to inoculation is in this case is increased for 1-2 hours and equals in general 3-5 hours.

The surface of the prepared in this way media was inoculated by suspensions of spores of *Aspergillus niger* and *Penicillium chrysogenum* mouldy fungi, containing 1 million spores/ml, putting 0.05 ml suspension in three symmetrical points on a surface of a medium in each dish. The dishes were incubated in the thermostat under 301 K during 120 hours. The average diameter of *Aspergillus niger* colonies on a medium prepared according to point 1 equals 15.8 ± 4.7 mm, on agar medium equals 15.6 ± 4.4 mm. The average diameter of *Penicillium chrysogenum* colonies on a medium prepared according to point 1 equals 13.8 ± 3.1 mm, on agar medium equals 14.1 ± 3.3 mm.

As an example, the comparative data of accumulation of yeasty and mouldy fungi biomass on hard nutrient media with a solid porous material and agar are indicated in the Table 1.

Table 1. Sizes of microorganism colonies on hard nutrient media with a solid porous material and agar

Species of microorganisms	Duration of incubation, hours	Solidifying basis	Average diameter of colonies, mm
Aspergillus niger	120	Solid material	16.0 ± 6.1
Aspergillus niger	120	Agar	16.4 ± 6.2
Penicillium chrysogenum	120	Solid material	14.0 ± 2.6
Penicillium chrysogenum	120	Agar	15.0 ± 3.1
Candida utilis	96	Solid material	7.1 ± 0.3
Candida utilis	96	Agar	6.7 ± 0.6

Saccharomyces cerevisiae	96	Solid material	6.8 ± 0.2
Saccharomyces cerevisiae	96	Agar	6.9 ± 0.4

Example 2. Dry hard microbiological nutrient media solidified by specially prepared solid porous materials were applied. These nutrient media were kept in usual room conditions during 1 year. All other operations are the same as in point 1.The average diameter of *Aspergillus niger* colonies on a medium prepared according to point 1 equals 15.8 ± 2.9 mm, on agar medium equals 15.6 ± 5.1mm. The average diameter of *Penicillium chrysogenum* colonies on a medium prepared according to point 1 equals 13.9 ± 4.6 mm, on agar medium equals 13.8 ± 3.1 mm.

Example 3. Hard nutrient Czapek's-Dox's medium, in which agar was replaced by a solid porous material with hardness on a Moos's scale equal 5 was prepared. Disks with a diameter 90 mm and thickness 8 mm, which were put in Petri dishes were made of it. Ingredients of Czapek's-Dox's medium were dissolved in distilled water, then with an received solution disks till saturation were impregnated. Prepared hard nutrient medium was sterilized in autoclave under 175 kPa during 30 min. The surface of prepared nutrient medium was inoculated by suspensions of spores of *Aspergillus niger* and *Penicillium chrysogenum* mouldy fungi, containing 1 million spores/ml, putting on each disk in three symmetrical points 0.05 ml suspension of one of fungi and after this dishes were incubated in the thermostat under 301 K.

In comparison in the same way poured out in Petri dishes sterile agar Czapek's-Dox's medium was inoculated. The dishes with inoculated agar medium were incubated in the same conditions. Each of four indicated variants was tested on 10 Petri dishes.

Example 4. Hard nutrient medium of non-hopped must with strength 7 º on polarimeter, in which agar is replaced by a solid porous material was prepared. A medium was inoculated by suspensions of yeast *Candida utilis* and *Saccharomyces cerevisiae* cells with concentration in 1 mln of cells/ml as is indicated in point 1. In comparison the sterile agar musty medium poured out in Petri dishes was inoculated in the same way. All other operations are the same as in point 1.

The comparative results in cultivation of microorganisms according to examples 3 and 4 (suspension of *Streptococcus* culture cells, taken from the patient with chronic tonsillitis

Table 2. Comparative results in cultivation of microorganisms on nutrient media solidified by a solid material and agar

Species of microorganisms	Duration of incubation, hours	Solidifying basis	Average diameter of colonies, mm
Streptococcus	48	Solid material	1 - 3
Streptococcus	48	Agar	1 - 3
Actinomyces flavus	288	Solid material	4.9 ± 0.6
Actinomyces flavus	288	Agar	5.0 ± 0.8

and suspension of *Actinomyces flavus* spores) on nutrient media, respectively, sterile meat-peptone medium with adding 10 % by volume of sterile serum of the bull blood and starch-ammonia medium of composition, namely, starch soluble (amilose) – 10g, $(NH_4)_2SO_4$ – 2g, 1g each of K_2HPO_4 , $MgSO_4$ and NaCl, water – up to 1.0 l are indicated in the Table 2. Sealing basis is solid porous material and agar.

Example 5. Disks with cultures of microorganisms from points 1 and 2 were autoclaved under 200 kPa during 30 min, were tempered under 873 K during 1.5 hours, cooled in the air, boiled in water 1 hour and dried up under 383 K up to constant weight. Then on the base of these disks hard nutrient media were prepared, which were inoculated and incubated as in points 3 and 4. The average diameter of *Aspergillus niger* colonies equals 16.5 ± 3.3 mm, *Penicillium chrysogenum* colonies equals 14.6 ± 2.5 mm, *Candida utilis* colonies equals 7.2 ± 0.2 mm, *Saccharomyces cerevisiae* colonies equals 6.7 ± 0.3 mm.

Table 3. Results in cultivation of microorganisms after two stages of solid solidifying basis regeneration [1)]

Species of microorganisms	Duration of incubation, hours	Solidifying basis	Average diameter of colonies, mm
Aspergillus niger	120	Solid material *	16.5 ± 3.3
Penicillium chrysogenum	120	Solid material *	14.6 ± 2.5
Candida utilis	96	Solid material *	7.2 ± 0.2
Saccharomyces cerevisiae	96	Solid material *	6.7 ± 0.3
Aspergillus niger	120	Solid material **	16.2 ± 3.4
Penicillium chrysogenum	120	Solid material **	14.2 ± 2.6
Candida utilis	96	Solid material **	7.3 ± 0.3
Saccharomyces cerevisiae	96	Solid material **	6.6 ± 0.4

[1)] Note: * – after the first stage of regeneration; ** – after the second stage of regeneration.

Example 6. Secondary regeneration of a solidifying basis was conducted. For this purpose the disks with cultures of microorganisms from point 5 were treated as in point 5. The average diameter of *Aspergillus niger* colonies equals 16.2 ± 3.4 mm, *Penicillium chrysogenum* colonies equals 14.2 ± 2.6 mm, *Candida utilis* colonies equals 7.3 ± 0.3 mm, *Saccharomyces cerevisiae* colonies equals 6.6 ± 0.4 mm.

The results of four species cultivation of microorganisms after two successive stages of solid solidifying basis regeneration, as in examples 5 and 6, are indicated in the Table 3.

Applying solid porous inorganic materials as a basis for hard microbiological nutrient media has advantage before usage of known solidifying matters, as the nutrient media prepared on the new basis, have higher mechanical strength. The solidifying basis is cheaper and accessible and can be used repeatedly.

The results of tests of hard microbiological nutrient media prepared by developed and known ways have shown that the developed way allows to prepare nutrient media with higher exploitative properties, provides essential reduction of duration and simplification of preparation process of media to an inoculation. It meets the requirements of express extraction pathogenic microorganisms from environment and their cultivating.

Influence of phosphate and maltose concentrations in the dextransucrose production by *Leuconostoc m. B-512-f*

M. Hernández, M. Peña Miranda*, G. González Benito
Department of Chemical Engineering and Environmental Technology
University of Valladolid. Pº Prado de la Magdalena s/n, 47011 Valladolid, Spain

Keywords: dextransucrose, dextran, *Leuconostoc mesenteroides*,

Abstract

In this work the obtention of the enzyme dextransucrose by *Leuconostoc mesenteroides B-512-f* has been made. The influence in the activity of the enzyme of phosphate concentration and the presence of the acceptor maltose was analysed. The technic of capilar electroforesis allowed identify dextransucrose as well as other enzymes in very low concentrations.

1 Introduction

Dextran $(C_6H_{10}O_5)_n$ is a high-molecular-mass polysaccharide of D-glucose, mainly linked by $\alpha(1\rightarrow6)$ glucosidic bonds in their major chains, which also possesses side-chains stemming 1-3, y 1-4 bonds (depending on the specific activity of dextransucrose). Dextran is a high added value product whose main applications are: blood-plasma substitute in the pharmaceutical industry, chromatographic separations, or as a sweetener and thickening agent in the food products.

The enzyme responsible for the synthesis of dextran is known as dextransucrose. These enzymes are synthesized from sucrose by various bacterial species from two genera *Leuconostoc mesenteroides and Streptococcus*. These enzymes are not however the only extracellular enzymes produced by these bacterium. Other enzymes able to produce others polymers are also generated, with the consequent negative influence on dextran production.

This research evaluated the influence of both phosphate and maltose concentration on the production of dextranosucrose by *Leuconostoc mesenteroides* B-512-f using sucrose as substrate, based on the hypothesis that the presence of activators can enhance the production of dextransucrose. Also the presence of other enzymes different to dextransucrose is studied.

2 Material and Methods

Microorganism

Leuconostoc mesenteroides NRRL B512-f from DSMZ (Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH) was used in the present investigation. The strain was stored at 4º C in Petri dishes of broth MRS (Cultimed) prior to inoculation. The inoculum was prepared by transferring bacterial colonies from Petri dishes to stirred E-flasks supplied with MRS broth and cultivated for 18 h at 30 ºC.

* Corresponding author. Tel + 34 983 423176. e-mail:pena@iq.uva.es

Dextransucrose was produced in a 1 L batch magnetically stirred tank reactor at 200 rpm. The fermentations were conducted at 23ºC and an initial value of pH of 7The composition of the medium was: 40 g/L sucrose, 20 g/L extract yeast; NaCl: 0,01 g/L; MnSO4·H2O: 0,01 g/L; FeSO4·7H2O: 0,01g/L MgSO4·2H2O: 0,20 g/L; CaCl2 : 0,10g/L {[5]. K2HPO4 concentrations ranged from 1 to 40g/L and Maltose concentrations from 2.5 to 10 g/L.

Analytical methods

The pH-value of every taken sample is analysed with a pH-Meter micropH 2002 (Crison). For the measurement of the optical density a spectrophotometer Hitachi U-2000 is used.

The method employed for determine the enzymatic activity of dextransucrose (measured as DSU) was described in a previous paper.

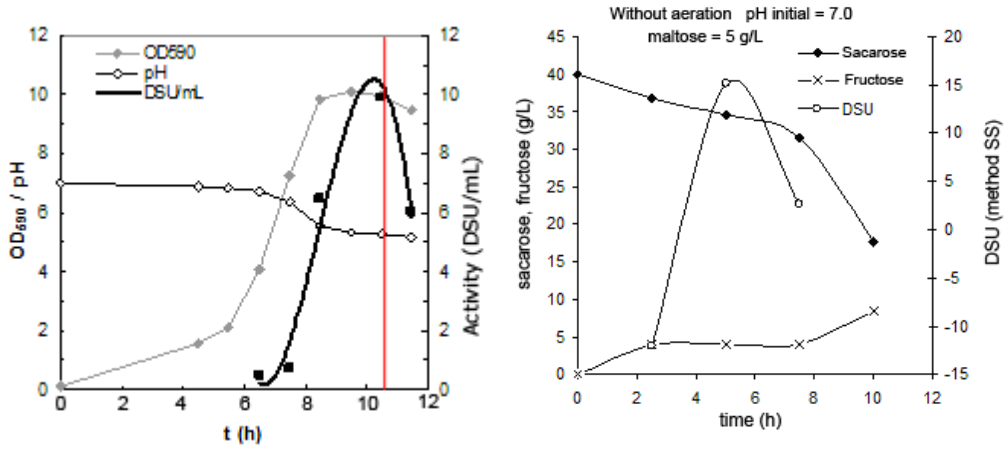
Analysis of carbohydrates was carried out by HPLC with an Aminex HPX-87-N column and a refractive index detector from Waters.

Electrophoresis in polyacrilamide gel with SDS (Bio-Rad MiniProtean III) was the technique used to identify dextransucrose.

3 Results

Influence of the acceptor maltose

Figure 1 show the results corresponding to two different fermentations, without maltose (a) and with a concentration of 5 g/L (b). As it can be seen the enzyme activity is higher when maltose is present in the fermentation medium.

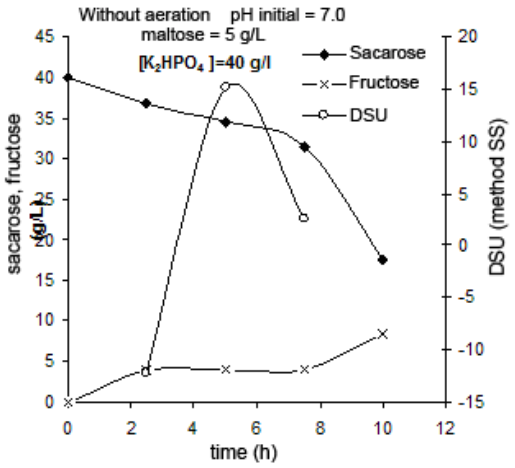


(a) (b)

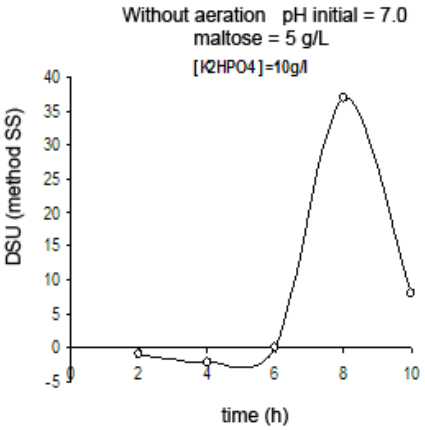
Figure 1. Enzymatic activity. Influence of maltose concentration: 0 g/L (a) and 5 g/L (b)

Influence of phosphate concentration

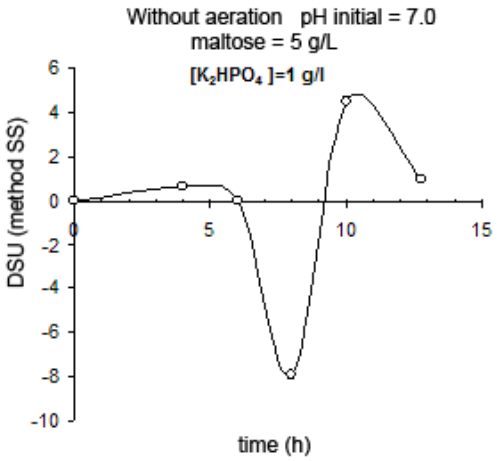
The results obtained in the essays with different concentrations of phosphate are depicted in figure 2: 40 g/L (a), 10 g/L (b) and 1 g/L (c). All experiments were carried out with 5 g/L of maltose.



(a)



(b)



(c)

Figure 2 Enzymatic activity. Influence of K_2HPO_4 concentration: 40 g/L (a), 10 g/L (b), 1 g/L (c)

From the obtained results, it can be established that 10 g/L of phosphate is the best concentration that let the maximal activity of the enzyme, for an operation time of 8 h. Next, new tests were established to determine the most adequate level of maltose for this concentration of 10 g/L of phosphate. The results depicted in figure 3 indicate that dextransucrose exhibited a greater activity in the presence of 5 g/l of maltose (up to 35 DSU).

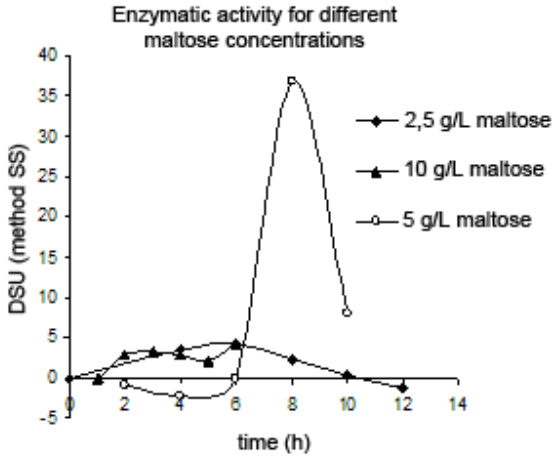


Figure 3 Enzymatic activity. Influence of maltose concentration

Identification of dextransucrose

In order to check the presence of enzymes different from dextransucrose, the gel electrophoresis technique was employed. The results are shown in figure 4. It can be seen a clear lane corresponding to a molecular weight of 190 kDa related to dextransucrose. Also, it appears diffuse lanes, that would indicate the presence of other enzymes in very low concentrations, and that could interfere in the activity of dextransucrose.

Keywords: Evaporation, Single and multiple-effect evaporators, Add-in, Spreadsheet.

Topic: Educating chemical and biological engineers for coming challenges.

Abstract

A software tool, in the form of an add-in for Microsoft Excel, was developed for design of single and multiple-effect evaporators. The program uses the Newton-Raphson method to solve the system of equations describing the evaporation unit, and is applicable to forward and backward feed systems, with negligible or significant boiling point raises. This software can be used as an helpful teaching aid, or as a good tool for operator training or for preliminary design of evaporator systems.

1. Introduction

The concentration of a solution of a non-volatile component is usually accomplished by evaporation (McCabe et al., 1993). Evaporators are used in different types of industries, including the food and the chemical industry. Due to the fact that evaporation is one of the most energy intensive separation processes, multiple-effect evaporators are usually used to reduce energy consumption. Indeed, in multiple-effect evaporators the decrease in energy consumption is roughly proportional to the number of effects when the boiling point raise is negligible. However, the corresponding increase in equipment cost limits the maximum number of evaporators to be used in a multiple-effect system for a given separation. The calculation of the optimum number of effects requires an exact design and cost evaluation of the evaporation system.

Evaporator calculations are usually iterative and tedious, a hard task to carry out manually. These calculations require solving a system of non-linear equations, corresponding to the mass and heat balances, the phase equilibrium and the heat transfer. Moreover, the data for enthalpy and boiling point raise (BPR) is usually available in the form of graphics and tables, which makes the calculations tougher and even more tedious. Therefore, the development of a software tool, easily accessible, for the design of single and multiple-effect evaporators will be an especially useful tool for engineers.

This work presents a computer program, developed in Visual Basic for Applications, and available in the form of an add-in for Microsoft Excel, a widespread working tool for engineers. The software is able to perform calculations of single and multiple-effect, forward and backward, evaporator systems with up to ten effects, having either negligible or significant boiling point raises. The model equations are solved by means of the Newton-Raphson method (Holland, 1975), which proved to be fast and reliable for this type of calculations.

* Corresponding author. Tel + 351-22-5081974. E-mail:fgm@fe.up.pt

2. Model equations

To design an evaporator system, the following equations must be solved: mass balances, energy balances, phase equilibrium equations (i.e., the relationships between the saturation temperature of the solution and that of the pure solvent at the same total pressure), and heat transfer equations (i.e., the equations used to calculate the heat transfer areas). To exemplify the type of equations used, the three-effect forward evaporator system, shown in Figure 1, will be considered. The equations that describe this evaporation unit are the following (Holland, 1975):

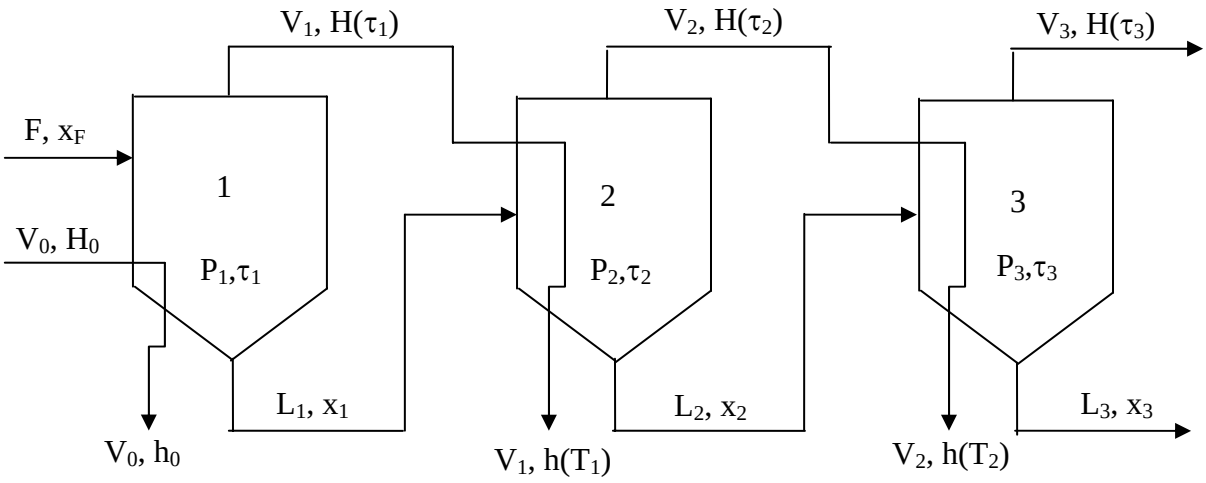

Figure 1 – Three-effect forward evaporator system

First effect:

$$f_1 = F[h(T_F,x_F) - h(\tau_1,x_1)] + V_0\lambda_0 - (F - L_1)[H(\tau_1) - h(\tau_1,x_1)] \quad (1)$$

$$f_2 = U_1A(T_0 - \tau_1) - V_0\lambda_0 \quad (2)$$

$$f_3 = \tau(T_1,x_1) - \tau_1 \quad (3)$$

$$f_4 = Fx_F - L_1x_1 \quad (4)$$

Second effect:

$$f_5 = L_1[h(\tau_1,x_1) - h(\tau_2,x_2)] + (F - L_1)[H(\tau_1) - h(T_1)] - (L_1 - L_2)\,[H(\tau_2) - h(\tau_2,x_2)] \quad (5)$$

$$f_6 = U_2A(T_1 - \tau_2) - (F - L_1)[H(\tau_1) - h(T_1)] \quad (6)$$

$$f_7 = \tau(T_2,x_2) - \tau_2 \quad (7)$$

$$f_8 = Fx_F - L_2x_2 \quad (8)$$

Third effect:

$$f_9 = L_2[h(\tau_2,x_2) - h(\tau_3,x_3)] + (L_1 - L_2)[H(\tau_2) - h(T_2)] - (L_2 - L_3)\,[H(\tau_3) - h(\tau_3,x_3)] \quad (9)$$

$$f_{10} = U_3A(T_2 - \tau_3) - (L_1 - L_2)[H(\tau_2) - h(T_2)] \quad (10)$$

$$f_{11} = \tau(T_3,x_3) - \tau_3 \quad (11)$$

$$f_{12} = Fx_F - L_3x_3 \quad (12)$$

where:

T_j – saturation temperature of pure solvent on effect j, at pressure P_j;

τ_j – boiling point temperature of the liquid solution on effect j, at pressure P_j and composition x_j;

$h(T_j)$ – enthalpy of pure solvent in the liquid state, evaluated at the saturation temperature T_j corresponding to pressure P_j on effect j;

$H(T_j)$ – enthalpy of pure solvent in the vapour state, evaluated at the saturation temperature T_j corresponding to pressure P_j on effect j;

$H(\tau_j)$ – enthalpy of the solvent in the vapour state, evaluated at the temperature of the liquid solution, τ_j, on effect j, corresponding to pressure P_j and composition x_j;

$h(\tau_j,x_j)$ – enthalpy of the liquid solution leaving effect j, evaluated at P_j, τ_j, and x_j;

$h(T_F,x_F)$ – enthalpy of the liquid feed, evaluated at the feed temperature, pressure and composition (T_F,P_F, x_F).

For calculating the solution temperature and enthalpy, the program allows the operator to fit the existing experimental data to Equations (13) to (15). Equation (13) correlates the data for the boiling point raise, BPR = $\tau_j - T_j$, which is usually in the form of a Dühring diagram, that relates the solution temperature to the pure solvent saturation temperature at the same total pressure. Equation (14) is used to correlate the available data for the solution enthalpy, which, alternatively, may be evaluated by means of heat capacity data (equation (15)).

$$BPR = ax^3 + bx^2 + cx + d + e/x + f/x^2 \quad (13)$$

$$H = aT^3 + bT^2 + cT + dx^3 + ex^2 + fx + g/x + h \quad (14)$$

$$C_P = aT^3 + bT^2 + cT + dx^2 + ex + f \quad (15)$$

The system of equations, f_1 through f_{12}, was solved by the Newton-Raphson method,

$$\underline{\underline{J}}_k \, \underline{\Delta X}_k = -\underline{f}_k \quad (16)$$

where $\underline{\underline{J}}_k$ is the system Jacobian, a 12x12 matrix of the partial derivatives of equations f_1 – f_{12} relative to the 12 project variables (i.e., V_0, τ_1, T_1, L_1, x_1, τ_2, T_2, L_2, x_2, τ_3, L_3, A), which is numerically evaluated, $\underline{\Delta X}_k$ is the vector of increments for the 12 unknowns in the k^{th} iteration, and $\underline{f}_k$ is the vector with the values of the 12 functions in the k^{th} iteration, which must be equal to zero when solution is reached. A more detailed discussion of the application of the Newton-Raphson method to solve the non-linear system of equations for multiple-effect evaporators can be found in Holland (1975).

3. Calculation example

The developed add-in for the calculation of the evaporator system allows the user to interact with the program by means of self-explanatory user-forms. The input data and the results are summarized in a spreadsheet.The add-in allows the operator to use this generated spreadsheet to run again the program for other conditions, without needing to type in all the input information. The program also allows the user to choose between giving the first estimates, which can be helpful when dealing with difficult converging problems, or letting the program to calculate them. The operator can also set the convergence tolerance and the maximum number of iterations. In the specification of the problem, besides the feed flowrate and the inlet and outlet solute concentrations, the pressure (or temperature) in the last effect, the pressure (or temperature) of the steam used as heating medium, and the enthalpic feed condition must be specified.

The application of the software will be exemplified by considering the concentration of a stream of 7500 kg/h of a solution of sodium hidroxide (NaHO), from 10-60%, in a 3-effect forward feed evaporation system. The remaining input data can be seen in Figures 2 and 3, which are screenshots of the input form and the spreadsheet generated by the program, respectively. The boiling point and enthalpy data for the NaHO solution was obtained by fiting Equations (13) and (14) to the curves of the Dühring and solution enthalpy diagrams, respectively, available in McCabe et al. (1993). This is a good example of a difficult converging problem, due to the significant boiling point elavation. Nevertheless, the solution was reached after 5 iterations, using first estimates generated by the program.

To further exemplify the potencialities of the developed add-in, the same example was also run assuming backward feed. The results of these calculations are shown in Figure 4.

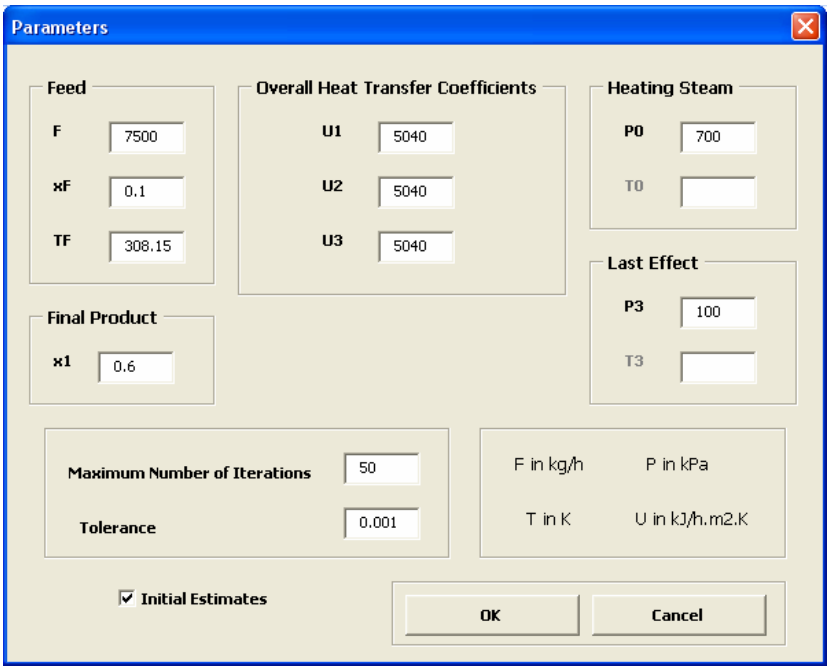

Figure 2 – Screenshot of the input form for a 3 multiple-effect evaporator system

4. Conclusions

An add-in for Microsoft Excel was developed for design of single and multiple-effect evaporators, with forward or backward feed, and having negligible or significant boiling point raises. The interaction with the operator is made by self-explanatory forms, and the physical data input by means of equations (eq. 13-15), whose constants may be obtained by fitting them to available experimental data. The resulting system of equations is solved by means of the Newton-Raphson method, which revealed to be reliable and fast for these types of calculations. The first estimative may be given by the operator, or generated by the program. The results and corresponding input data are summarized in a spreadsheet, which can be used by the program as an input file to run other examples under different initial conditions.

This software can be used as an helpful teaching aid, and as a good tool for operator training or for preliminary design of evaporator systems.

Process synthesis for hydrogen production from glucose: bioreactor design and scale-up and downstream process

Alice M. de Lima, Adilson J. de Assis[1*]
[1] School of Chemical Engineering, Federal University of Uberlandia
Av. Joao Naves de Avila 2121 Bl. 1K, Campus Santa Monica, 38408–100 Uberlandia MG, Brazil.

Keywords: Reactor scale-up; hydrogen from biomass; separation; process simulation.
Topic: Educating chemical and biological engineers for coming challenges.

Abstract

Recognized as one of the most promising energy carrier of the future hydrogen can be produced using several sources, renewable or not. Amongst the renewable alternatives, some have been distinguished as the most promising, such as: electrolysis of water, electrolysis of steam, thermochemical decomposition of water, photoelectrochemical processes, biophotolysis of water, photodecomposition of organic compounds, ethanol reforming and fermentation of organics. The fermentation of organic compounds is considered one of the most promising sustainable alternatives in the future for hydrogen production from biomass. On this basis, this work aims to discuss the integration of the following subjects in process synthesis and design: experimental data published in literature; bioreactor design and scale-up; synthesis of downstream process; process simulation; technical-economic viability analysis, and sustainability. The authors hope that the integrated methodology presented here can help senior process design course instructors to plan their activities.

1 Introduction

Recognized as one of the most promising energy carrier of the future hydrogen can be produced using several sources, renewable or not. Amongst the renewable alternatives, some have been distinguished as the most promising, such as: electrolysis of water, electrolysis of steam, thermochemical decomposition of water, photoelectrochemical processes, biophotolysis of water, photodecomposition of organic compounds, ethanol reforming and fermentation of organics. The fermentation of organic compounds is considered one of the most promising sustainable alternatives in the future for hydrogen production from biomass (Liu et al., 2008; Vijayaraghavan and Soom., 2008).

On this basis, this work aims to do a technical-economic viability analysis of hydrogen production by fermentation route considering bioreactor design and scale-up as well as downstream process. It will be discussed the integration of the following subjects in process synthesis and design: experimental data published in literature; bioreactor design and scale-up; synthesis of downstream process; process simulation; technical-economic viability analysis, and sustainability.

The authors hope that the integrated methodology presented here can help senior process design course instructors to plan their activities.

2 Reactor design and scale-up

The species from the genus *Clostridium* are known as acid producers and usually they can ferment glucose to butirate, acetate, carbon dioxide and molecular hydrogen. The following reactions show

*Corresponding author. Tel. +55-34-3239-4292. E-mail: ajassis@ufu.br

hydrogen production trough fermentation of glucose:

$$C_6H_{12}O_6 \longrightarrow 2CH_3COOH + 4H_2 + 2CO_2 \quad (1)$$

$$C_6H_{12}O_6 \longrightarrow C_3H_7COOH + 2H_2 + 2CO_2 \quad (2)$$

$$C_6H_{12}O_6 \longrightarrow 2C_2H_5OH + 2CO_2 \quad (3)$$

Lin et al. (2007) carried out a series of experiments with four species of *Clostridium* and proposed a Monod like kinetic model modified by an empirical law that takes into account pH inhibition (I_{pH}). Amongst the studied microorganisms, *C. beijerinckii* presented the greatest productivity, whose parameters of reference had been used in this work.

For the rate of glucose consumption, it was used the expression $r_{glu} = (q_{Glu}^{max} S_{Glu} X)/(K_{Glu}+S_{Glu}).I_{pH}$, where *X* denotes biomass concentration, q_{Glu}^{max} maximum specific glucose consumption rate, S_{Glu} residual glucose concentration, and K_{Glu} Monod half-saturation constant. The empirical lower pH inhibition term, I_{pH}, according to Lin et al. (2007), was defined as being $I_{pH} = exp(-3((pH - pH_{UL})/(pH_{UL} - pH_{LL}))^2)|_{pH<pH_{UL}}$, where pH_{UL} and pH_{LL} represents the upper limit at which bacteria are not inhibited (I_{pH}=1 when pH > pH_{UL}), and the lower limit at which inhibition is complete. Using the experimental and kinetic data presented by Lin et al. (2007), new kinetic parameters model were adjusted in this work, considering only glucose as limiting substrate.

After that, bioreactor scale-up was accomplished (stirred batch reactor), using mathematical unsteady-state mass balances (Bailey and Ollis, 1986) and computer simulation. The glucose consumption was directly calculated, and the changes in biomass (*X*), hydrogen (C_{H_2}), carbon dioxide (C_{CO_2}), butanol ($C_{Butanol}$), lactic acid (C_{HLa}), acetate (C_{HAc}) and butyrate (C_{HBu}) concentrations was calculated using the stoichiometric relations as shown in Table 1.

Table 1: Stoichiometric matrix of glucose fermentation

	S_{glu}	S_{HAc}	S_{HBu}	S_{H_2}	X
Glucose consumption	-1	$(1-Y)f_{HAc}$	$(1-Y)f_{HBu}$	$(1-Y)f_{H_2}$	Y

In order to perform the reactor design and scale-up, a suitable dynamic model was developed through mass balances. The model is a set of ordinary differential equations with initial value problem as showed in the following equations:

$$\frac{dS_{Glu}}{dt} = -r_{Glu} \quad (4)$$

$$\frac{dX}{dt} = -Y.\frac{dS_{Glu}}{dt} \quad (5)$$

$$\frac{dC_{H_2}}{dt} = -(1-Y).f_{H_2}.\frac{dS_{Glu}}{dt} \quad (6)$$

$$\frac{dC_{CO_2}}{dt} = -Y_{CO_2}.\frac{dS_{Glu}}{dt} \quad (7)$$

$$\frac{dC_{Butanol}}{dt} = -Y_{Butanol}.\frac{dS_{Glu}}{dt} \quad (8)$$

$$\frac{dC_{HLa}}{dt} = -Y_{HLa}.\frac{dS_{Glu}}{dt} \quad (9)$$

$$\frac{dC_{HAc}}{dt} = -(1-Y).f_{HAc}.\frac{dS_{Glu}}{dt} \quad (10)$$

$$\frac{dC_{HBu}}{dt} = -(1-Y).f_{HBu}.\frac{dS_{Glu}}{dt} \quad (11)$$

The model was solved using the free software Scilab (www.scilab.org) with **ode** function and **lsoda** integrator. With the new parameters adjusted in this work, it was obtained a good concordance between simulated (this work) and experimental data (Lin et al., 2007), as showed in Figure 1.

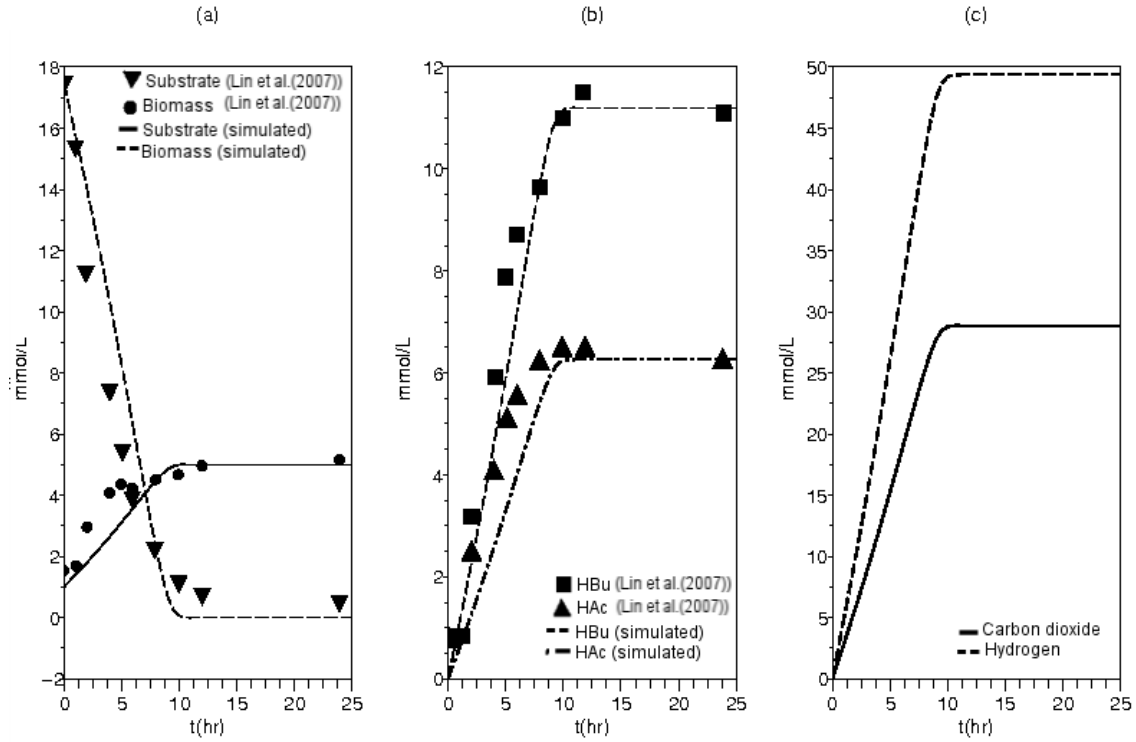

Figure 1: Simulation result for: (a) substrate and biomass concentrations, (b) acids concentrations, (c) gases.

3 Downstream process synthesis

The proposed downstream process is constituted basically by:

1. Gas separation subsystem, with hydrogen recovery and compression; it was also considered the purification and compression of carbon dioxide as valuable byproduct;
2. Liquid separation, namely acetic and butyric acids, by means of liquid-liquid extraction and distillation.

The process flowsheet synthesis was accomplished following the conceptual design methodology proposed by Douglas (1988) at level 4, and it is shown in Figure 2. For CO_2 capture, it was considered absorption with MEA and a 99% of recovery, as reported in the literature. The vapour phase from exit reactor is feed in an absorber tower (T-101) bottom and the solvent solution on the top of it. Inside the absorber, the absorvent solution (MEA) reacts chemically with carbon dioxide from effluent gas. The gas rich in hydrogen follows to the section of recuperation and compression. The solution rich in carbon dioxide follows to the regeneration tower (T-102). In this column, CO_2 is withdrawn from MEA through temperature increase. The solvent (MEA) is colled in heater exchanger (E-101) to increase the solubility of CO_2, making it possible the absorption operation. The CO_2 liberated in stripping column follows to compression (C-101 and C-102) and cooling (E-102 and E-103), allowing gas condensation on technically viables temperatures, what is realized in two stages. The gas is then sent to a flash vessel (V-101) for withdrawn of vapour and solvent. After that, it is compressed (C-103) and colled (E-104), and then sent to an adsorption column (T-103) that uses silica gel as dessicant agent, to remove moisture from gas mixture, avoiding ice formation in the next heater exchanger (E-105). In sequence, CO_2 is sent to be stored (V-102).

To recuperate and compress hydrogen, the gas stream from absorption tower (T-101) is cold in a heater exchanger (E-201), compressed (C-201) and then follows to a flash vessel (V-201), where water and CO_2 are separated. To remove traces of CO_2, the mixture is colled (E-202) and follows to a flash (V-202). The liquid stream from flash is sent to a section that captures CO_2. The vapor phase exiting V-202 follows to another stage of compression (C-202), where it is compressed to 340 atm, the usual pressure to store

liquid hydrogen.

Separation of liquid stream is done by liquid-liquid extraction tower (T-301). The stream rich in butyric acid (extract phase) is heated (E-301) and sent to a flash (V-301) for withdrawn of water and then heated again (E-302). The stream 35 (water, butyric and acetic acids, and solvent – decanol or oleyl alcohol) is sent to a first distillation column (T-302), where the distillate product is a acetic solution, and the bottom product follows to the second distillation column (T-303), where the top product is a butyric acid solution, and the bottom product returns to the extractor column.

The proposed downstream process flowsheet was simulated using the free software and chemical processes simulator Sim42 (Assis and Oliveira-Lopes, 2005; Assis et al., 2006) with VMGSim interface from Virtual Materials (www.virtualmaterials.com). Peng-Robinson and Advanced Peng-Robinson were used as thermodynamic package in all simulations. Simulation shows that it is possible to obtain hydrogen with a high purity (0.999%), which increases the yield of fuel cells using hydrogen and oxygen as reactants for energy generation.

4 Economic evaluation

The costs of the equipments were calculated using the methodology proposed by Peters and Timmerhaus (1991) and Henley and Seader (1981). For reaction and gas separation subsystem, the mainly direct annualized costs are showed on Table 2, using a return rate of 20%. The installed costs were estimated with inflaction factor indices of year 2000 (CEPCI=392.4 and MSI=1089). The costs of utilities, maintenance, start-up, piping, instrumentation and control, were estimated according to Peters and Timmerhaus (1991). All calculations were done using Scilab.

The accuracy of a "preliminary design estimate" is typically -30% to +50% (Peters and Timmerhaus, 1991). At this level of accuracy, the resulting costs of production were 1.17 USD and a profit of 0.66 USD for kilogram of produced hydrogen. Thus, the cost of hydrogen production by fermentation reveals to be economically attractive, and more viable than the gasification of the biomass, that presents a cost of production of 2.2 USD for kilogram of H_2, approximately.

Table 2: Direct and Indirect costs of process.

Equipment	Installed Cost ($)	Annualized Cost ($/year)
Fermentor	2,980,636.00	596,127.00
Stirrer	69,834.00	13,968.00
V-101	134,537.00	26,908.00
T-103	49,443.00	9,889.00
C-101	32,700.00	6,540.00
C-102	21,800.00	4,360.00
C-103	14,170.00	2,834.00
V-201	328,869.00	65,773.00
V-202	127,437.00	25,487.00
C-201	1,417.000.00	283,400.00
C-202	872,000.00	174,400.00
Total	6,048,425.00	1,209,685.00
Annual Profit		6,285,505.00
Utilities		241,937.00
Maintenance		96,775.00
Start-up		120,969.00
Piping		241,937.00
Instrumentation and Control		96,775.00
Annual Profit		5,487,112.00

5 Conclusions

Although in initial steps of development, the technology of hydrogen production by fermentation reveals to have both technical and economical viability. In this work, it was presented a preliminary design flowsheet considering reaction and downstream. The profit showed to be attractive and detailed flowsheet and cost estimates should be done in further investigations. Based on the steps presented here, the student can see how to integrate basic and technical information in sustainable process design and simulation. Furthermore, the authors hope that the integrated methodology presented here can help senior process design course instructors to plan their activities.

Topic: Educating chemical and biological engineers for coming challenges

Abstract

The new reorganization of university education according to the European Higher Education Area (EHEA) guidelines involves relevant changes in teaching and learning methodologies. In this sense specific strategies will have to be implemented in order to help students to learn more successfully and to develop important skills and competences requested by the professional world. The subjects included in each level of education degree will be design in terms of learning outcomes and competences. Learning outcomes will be defined on basis of specific contents developed in each subject whereas the acquisition of skills requires a parallel programming of them. A summary of the main progress in competence training for chemical engineers of Valladolid University got up to now is presented in this work. Moreover, main transferable skills are identified, the possibilities and resources to develop them within our actual program of studies are analysed, including a detailed description of an educational activity based on a case study methodology, and a reflection of evaluation procedure is done.

1. Introduction

The education of chemical engineers in the frame of Bologna process must be focused not only to develop learning outcomes directly connected with knowledge but also transferable skills. In this sense, the new European Higher Education Space involves an important modification of the actual teaching-learning system, based on the use of new methodologies to help student to acquire the knowledge and the skills and competences requested by the professional world.

The teaching and learning methods should also help to develop students' skills (Molzahn, 2006), to work both independently and in teams. Thus, to learn to function in teams, group work is necessary. To be able to communicate, communication tasks must be given and solved. To learn to learn and to take responsibility for their own learning, students must receive appropriate self-study and problem solving tasks during their study. To understand ethical, societal, environmental and professional issues, suitable examples for illustration or discussion must be included (Felder & Brent, 1999).

Recent studies have revealed that the majority of chemical engineering graduates find employment in a wide range of industries including oil, petrochemicals, pharmaceuticals, biotechnology, food and the environment. Chemical engineers are professionals able to tackling a wide variety of problems: turn laboratory bench-top phenomena into production processes, have an integrated approach to systems, work within and often manage teams of theoretical and experimental chemists, mechanical and civil engineers, accountants and health and safety officials, apply fundamental scientific understanding and engineering principles to industrial, laboratory and molecular processes. The new working positions require the development of general and transferable skills besides chemical engineering knowledge. As a consequence universities should place more emphasis on developing

students' transferable skills (Grant and Dickson, 2006).

In this work the main progress in competence training for chemical engineers of Valladolid University got up to now is presented. The partial objectives to be carried out in order to get this global aim are the followings:

1. Identify the main transferable skills for chemical engineering curricula
2. Adapt the subject programmes to help students to develop these transferable skills
3. Evaluate the student's competence and knowledge acquisition levels

2. Identification of transferable skills

Taking as reference the analysis extracted from numerous studies related to accreditation of engineering programs contributed by leaders of universities, associations or professional bodies (ICheme, ABET, ANECA, WCEC and UVa) have revealed that the most important generic attributes for chemical engineers are connected with the capacity to communicate effectively, including in english, the ability to work in multidisciplinary teams, the capacity to understand the basic principles underlying chemical engineering and be able to use them to set up and to solve problems and the ability to learn on his/her own, and have a recognition of the need for life-long learning (Cartón *et al*., 2007). As an example, the relevance and development degree of transferable skills and abilities to work as chemical engineers in a scale 1 to 5 (1 means very low and 5 very high) are presented in **Figure 1** (WCEC, 2004).

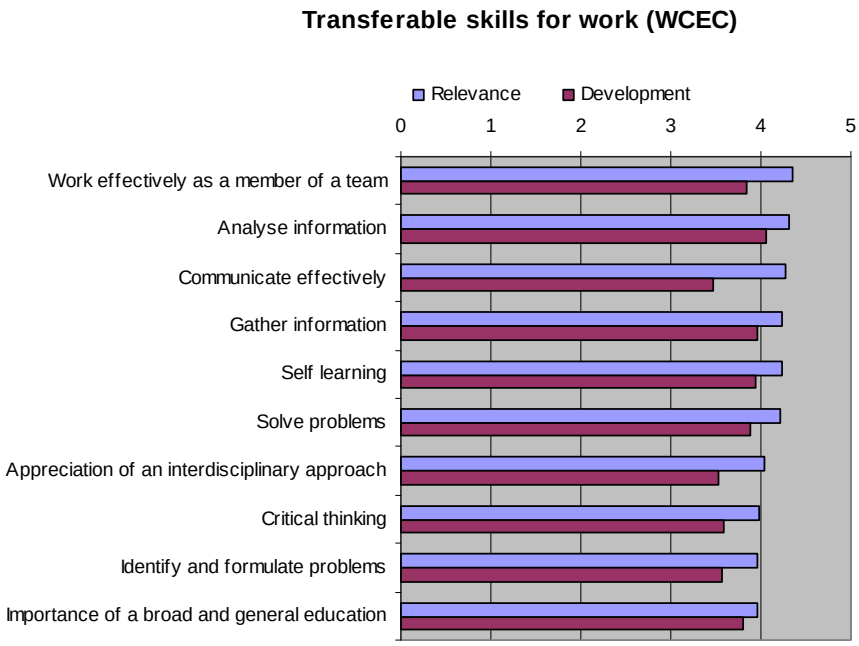

Figure 1. Relevance and development degree of transferable skills to work as chemical engineers.

3. Teaching and learning strategies for transferable skills acquisition

Integrated and global teaching and learning methodologies have been carried out in Chemical Engineering Degree at Valladolid University to help students to develop these transferable skills The learning objectives were established not only for every one of the specific subjects considered but also for the general skills to be acquired for the student. So, these learning methodologies include classical theoretical and practical classes but also propose individual and team works. Different activities such as oral presentations, written reports, discussion sessions, conferences and technical visits have been planned for all the semester subjects (Lucas *et al.*, 2008). Moreover, new methodologies for improving these

transferable skills were applied. In this sense, as an example, Based Problem Learning or appropriate computational tools facilitate the application of basic principles to problem resolution, the preparation of written reports, mini-projects and oral presentations improve the student capacity to communicate effectively or common collaborative techniques such as jigsaw, peer review, brainstorming or case study promote the learning based on work in teams (De Miguel, 2006).

In this paper a common activity based on the ***case study methodology*** applied to a real industrial production process is analyzed. This learning strategy is the main part of the global course activities developed and implemented in the seventh semester of a 5 years Chemical Engineering Degree and allow to integrate the different subjects involve in this course: Chemical reactors, separation processes, environmental technology and process instrumentation. The students, working in teams, study the proposed chemical process initially as a whole and later defined in different blocks. For each subject, different block aspects were detailed: selection of alternatives, operation mode, dimensioned for the equipment selected, system analysis, etc. At the final of the semester, students present the main results in a written report and also in an oral presentation in public session with all the teaching staff involved in the course, invited professionals and the rest of students. After every presentation, a discussion time is programmed in order to establish the main considerations to be made for every problem proposed.

The main objectives of the proposed methodology were to provide to the student with a holistic, integrated and applied vision of the different subjects involved in Chemical Engineering and at the same time to help students to develop transferable skills (team work, communication skills, life long learning).

The partial objectives to be carried out in order to develop and implemented this methodology were:

1. Adapt the programs of the different subjects to the total available workload of the students (ECTU) including the learning outcomes and the general abilities and competences previously established
2. Select and plan the case study. Production of ethanol from sugar beet was the selected industrial process for this course
3. Programme the different activities and elaborate an specific schedule for students that includes oral presentation and written reports, tutorial sessions, conferences, technical visits (student guide)
4. Evaluate the learning strategy as a whole taking into account the academic results (skills and knowledge acquisition) and the global learning process (planning, coordination, workload, etc.)
5. Create effective virtual case study course with Moodle that includes forums, textual resources (general information related to educational methodology, chemical engineers abilities and evaluation criteria; textbooks and exercise books), home-learning resources (video recordings, audio recordings), demonstration resources (laboratory experiments, simulators…), quizzes (partial evaluations), calendar (global, group and user events) and other activities (technical visits, conferences, upcoming events). The global structure of the virtual course is shown in **Figure 2**.

A complete description of case study methodology can be found in previous works (García Cubero *et al.*, 2007 and 2008)

4. Teaching and learning process evaluation: transferable skills and knowledge acquisition levels

Figure 2. Structure of case study virtual course.

Academic results of students during the last three years are collected in **Figure 3**. All students involved in the case study activity pass the evaluation. Most of students (> 70%) are in the range of qualifications 7 – 9 (good/very good) and a 25% of students are in the range of 9-10 (excellent). These results indicate the high motivation and implication level of the students in the activity proposed. Moreover during the last course, when virtual course was implemented in Moodle, no significant differences have been found in the students yield.

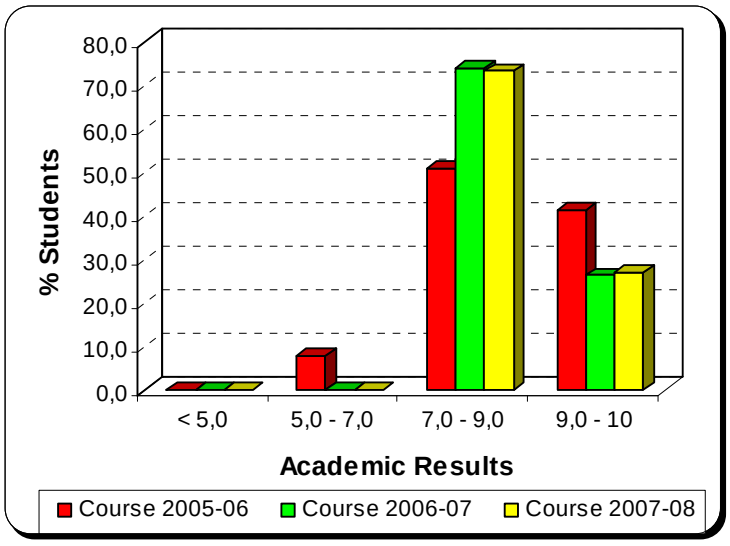

Figure 3. Trend in the academic results of students in the case study activity.

As it has been mentioned previously, one of the main objectives of this activity was to provide the student an integrated vision of the subjects involved in the seventh semester of the degree. Moreover, the acquisition of important transferable skills as team work, communication skills, etc. are intended to promote with the implementation of this learning strategy. A questionnaire with 15 transferable and specific skills was prepared. Both students and teachers evaluate every one of the skills in a 1 to 5 points scale (very low to very high) with a double sense: firstly the relevance that every item had for them and secondly the level of acquisition got with the proposed methodology in the case study activity. Results are summarized in **Figure 4.**

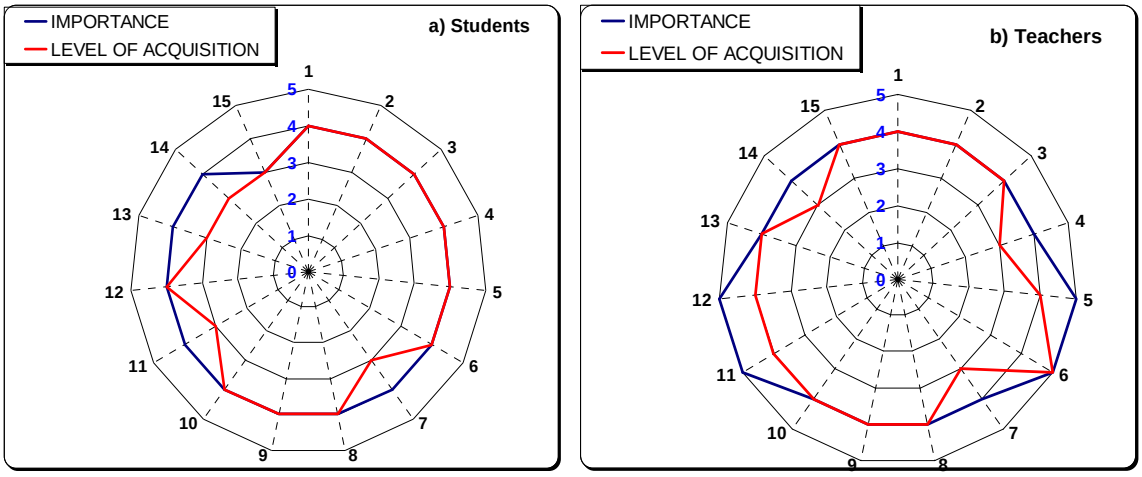

Figure 4. Results of skills evaluation procedure of case study activity.

From the analysis of **Figure 4** it can be concluded that teachers and students consider with a high punctuation (always higher than 3) the majority of transferable and specific skills evaluated. Only the written communication skills obtained a lower importance level. From a point of view of the level of acquisition, students recognize, according to their perception, a good level of acquisition (higher than 4) for most of the items tested, except those involved with oral and written communication skills (items 7 and 15 in Figure 4a) and the integration of operations and processes with the aim to attain global improvements (item 11 in Figure 4a). Teachers appreciate specific skills in a higher extent than transferable ones and assign a higher level of acquisition than students opinion showed, except on oral communication skills (item 7 in Figure 4 b) and leadership and making decision skills (item 4 in Figure 4b).

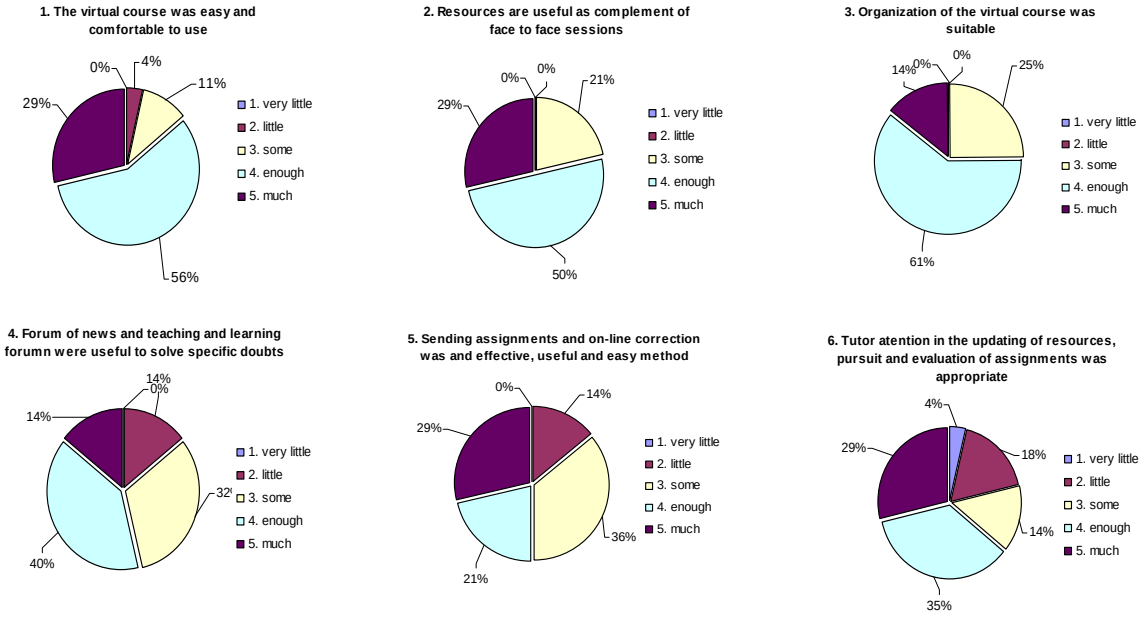

Figure 5. Student's opinion about the virtual case study.

Finally, **Figure 5** shows students opinion about the virtual case study used as a complement during the last course. The tool is easy or very easy to use for more than 80% of students. A 75% consider that resources (power point slides, information resources, web links, etc…) and organization of the virtual course result appropriate. However, teaching and learning forums has not attained a good evaluation: more than 30% of students consider forums useless. The use of Moodle to send the different assignments, to evaluate and to check qualifications is considered very positive for the 50% of students and the tutor attention is adequate or very adequate for more than 60% of students.

5. Conclusions

1. Case study is an effective tool to promote the holistic, integrated and applied vision of the different subjects involved in the seventh semester of the Chemical Engineering degree. At the same time, this new methodology help students to develop transferable skills of importance for their professional future (team work, communication skills, life long learning, etc) without resigning to the theoretical contents of each subject (knowledge acquisition)
2. The use of a virtual course as a complementary tool has allowed maintaining continuously updated resources, activities, etc. Moreover the teaching and learning forums allow the opinions and information exchange among teams and teachers involved in the activity.
3. The combination of technology-based materials and face-to-face sessions, allow developing innovative ways to motivate people to learn, provide greater access to information, help students learn conceptual matters and allow developing interpersonal skills.

Another basic segregation mechanism in aerated gravity flows of particulate solids

Dolgunin V.N.*, Kudy A.N., Klimov A.M. and Ivanov O.O.
Department of Technological Equipment and Food Technology,

Keywords: granular material, gravity flow, mixing, segregation, migration
Topic: Advancing the chemical engineering fundamentals (Particulate systems)

Introduction

Transversely aerated gravity flows of particulate solids are used widely in particle technology for the processes of heat-mass transfer and dust removal as well as for pneumatic transport in open channel. The results of experimental and analytical investigations presented earlier in [1] have shown that the aeration intensity and aeration direction considerably influence the segregation-mixing process in gravity flows of non uniform particles.

The prediction of segregation effects in aerated gravity flow of particles is of great significance for the industrial application because segregation may considerably upset the mixture uniformity which will influence the character of the subsequent technological processes and the quality of the finished products.

Earlier in the work [1] in order to forecast the segregation-mixing effects in aerated gravity flows of particulate solids differing in size and density the general segregation model [2] was adapted. In our further investigation [3] the general segregation model was developed by means of a closer definition of segregation kinetics and consideration of a quasi-diffusional separation mechanism. In the present paper this model is used in the experimental and analytical research on segregation in aerated gravity flow of particulate solids in order to reveal more accurately physical segregation mechanisms.

Experimental

The technique and the apparatus were analogous to the ones used earlier in the work [1]. The test unit (Fig. 1) consists of an inclined open channel of square cross-section 1 with a rough bottom. The slope of the channel can be adjusted. There is a horizontal tray 3 which used to collect the particles falling down the channel. To determine the particle distribution along the bed depth the tray contains cells 4. The slide–valve 2 is installed at the top of the channel to control the depth and the length of the moving bed.

The bottom of the channel is made of a steel plate 9 with holes 8 mm in diameter. The total holes area equals ≈ 70% of bottom area. The perforated plate 10 below the bottom is installed to distribute the air flow uniformly. The diameter of the plate holes and their total area are much smaller than the diameter and the total area of the holes in the bottom.

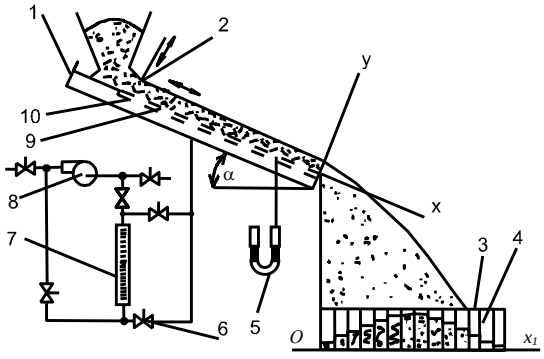

Fig.1 Schematic of test unit:

* Corresponding author. E-mail: ioo_c4@rambler.ru

Under the perforated plates there is a box connected with the air pipeline. Valves 6 are designed to control the air flow rate and to change the direction of the bed aeration. A rotameter 7 is used to measure the air rate. A differential micro-air-pressure gauge 5 is used to measure the pressure differential in the bed.

The research was carried out in the steady-state sliding flow of particulate solids [1] close to the boundary of the splashing flow. Such a state exists in a non-aerated gravity flow on a rough incline at the slopes approximate to the material angle of repose. During the aeration the above mentioned flow state is achieved by a corresponding variation of the slope. While varying the intensity of aeration the slope of the chute is changed so as to ensure sticking of the particles in the bottom analogous to the sticking taking place in non-aerated particle flow. The adequacy of particle sticking conditions is determined visually after the particles have flown down. Besides the adequacy of the flow state is controlled using the method proposed by Ishida et al [4].

According to the data described in [4] the minimum flow depth of rolling particles is registered at the boundary between the sliding and splashing flows. A similar dependence between the bed depth and the state of the particulate solid flow is registered in the present research both during aeration in the direction to the free surface and during aeration towards the bottom. The material flow depth was the same in both cases. This depth doesn't depend on the intensity of aeration.

The following experimental procedure is used. After setting the required chute slope α as well as the length of the incline and the air rate the material is metered out into the chute at the required feed rate. When the flow stationary state is achieved (which is determined experimentally) the particles go into the receiving tray.

Thus the profiles of velocity, the fraction of void volume and the test particles distributions along the bed depth were defined experimentally. These results were defined on the basis of the experimental data including bed depth in the channel h, channel inclination angle α, particles distribution function along the tray and vertical distance between the tray and the discharge threshold of the channel.

Taking into consideration the problems arising during direct experimental determination of the velocity and concentration profiles and also the void volume distribution along the thin bed depth for a rapid gravity flow of particles the present investigation was carried out by using the previously discussed experimental-analytical method [1]. The method is based on the combined analysis of the above mentioned experimental data using the law of a free falling body and taking into account the function of the interrelationship between the dilatation, shear rate and pressure along the bed depth [2]. This function was defined using the analogy between the particulate medium at a rapid shear flow and a dense gas as follows

$$p_t \bar{\varepsilon} = \psi \vartheta \tag{1}$$

where p_t is the total pressure of the particulate medium, $\bar{\varepsilon}$ is the shear flow dilatation [2], ϑ is the granular material 'temperature', expressed as a function of the shear rate [2], ψ is the coefficient of the physical and mechanical properties of the particles which is determined during modeling.

The total pressure $p_t(y)$ for the aerated gravity flow was defined as the sum of the hydrostatic pressure $p_s(y)$ analogue and the hydrodynamic pressure $p_d(y)$, generated by the aerating flow.

At small values of the air velocity (Re - number) the Kozeni-Karman equation is used for the hydrodynamic pressure determination.

Thus the total granular medium pressure is expressed in the following integral form

$$p_t(y) = p_s(y) + p_d(y) = \int_{h-y}^{h} \rho(1-\varepsilon(y)) g \cdot \cos\alpha \cdot dy + \int_{h-y}^{h} \frac{\lambda}{\varphi d_c(y)} \cdot \frac{\rho_g w^2}{2} \cdot \frac{1-\varepsilon(y)}{\varepsilon(y)^3} dy \tag{2}$$

where λ is the hydraulic resistance coefficient; d_C is the equivalent channel diameter in the bed of particles. This diameter is calculated as a function of the void volume fraction and mean particle diameter

$$d_C(y) = \frac{2\sqrt{3}}{\pi}\left(\sqrt[3]{\frac{1-\varepsilon_0}{1-\varepsilon(y)}}\right)^2 \cdot d - d \qquad (3)$$

The hydraulic resistance coefficient λ is expressed by an iteration procedure as the following function of Re

$$\lambda = A \cdot \mathrm{Re}^{-0.46}, \ \mathrm{Re} = 20 \div 150 \qquad (4)$$

where $A = 5 \div 8$

According to the procedure described in the work [2] and taking into account the above mentioned relations we have investigated the profiles of velocity and the fraction of void volume in the aerated gravity flow of silica gel and supephosfate granules differing in size. The investigation was carried out during the aeration oriented from the bed bottom to its free surface as well as to the reverse direction and without aeration.

As an example Fig.2 shows the profiles of velocity and the fraction of void volume in gravity flows of silica gel granules, which demonstrate the significant aeration effects depending on the aeration intensity and the aeration direction.

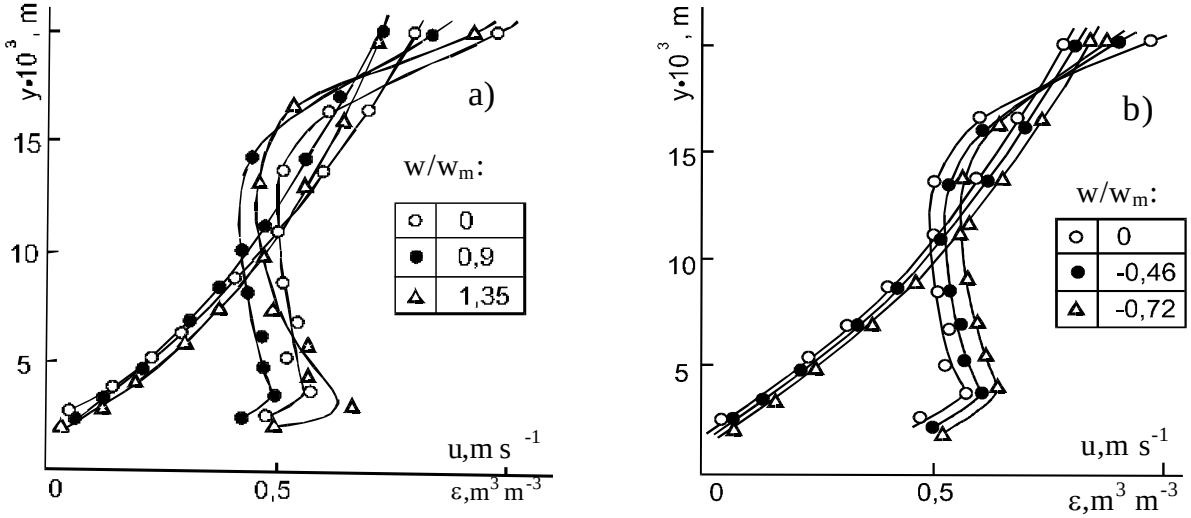

Fig.2. Profiles of velocity $u(y)$ and the void volume fraction $\varepsilon(y)$ in the gravity flow of silica gel granules (-3.75+3.5mm -50%; -4.25+4.0mm -50%) for various aerating air velocity w / w_m towards the free surface of the bed (a) and towards the bottom of the bed (b).

Analytical

In order to reveal more accurately physical mechanisms of aeration influence on particle segregation in gravity flows the mathematical modeling of segregation dynamics is carried out on the basis of the recently developed mathematical model [3]. For steady twodemensional shear flow the general equation of segregation dynamics is formulated as follows

$$\frac{\partial c \cdot \rho_b}{\partial t} = -\frac{\partial(u \cdot c \cdot \rho_b)}{\partial x} + \frac{\partial}{\partial y}\left(\rho_b\left(D_{dif} \cdot \frac{\partial c}{\partial y} - D_m \cdot c \cdot \frac{\partial \ln s}{\partial y} - K \cdot \Delta M \cdot c\right)\right) \qquad (5)$$

It takes into account the fluxes of convection, quasi-diffusional mixing, migration and hydromechanical segregation. In case of rapid shear flows of cohesionless non-elastic spherical particles all the parameters in Eq.(5) excluding coefficient *K* are calculated analytically as functions of traditional physical and mechanical characteristics of particles and flow parameters [3]. Only the kinetic constant *K* is determined experimentally by the method described in Ref [3].

The segregation driving force ΔM in aerated flows is calculated as the excess momentum of forces acting on the test particle [1] in nonuniform particulate media. This momentum is calculated according to the schematic of particle interactions in aerated gravity flows shown in Fig.3.

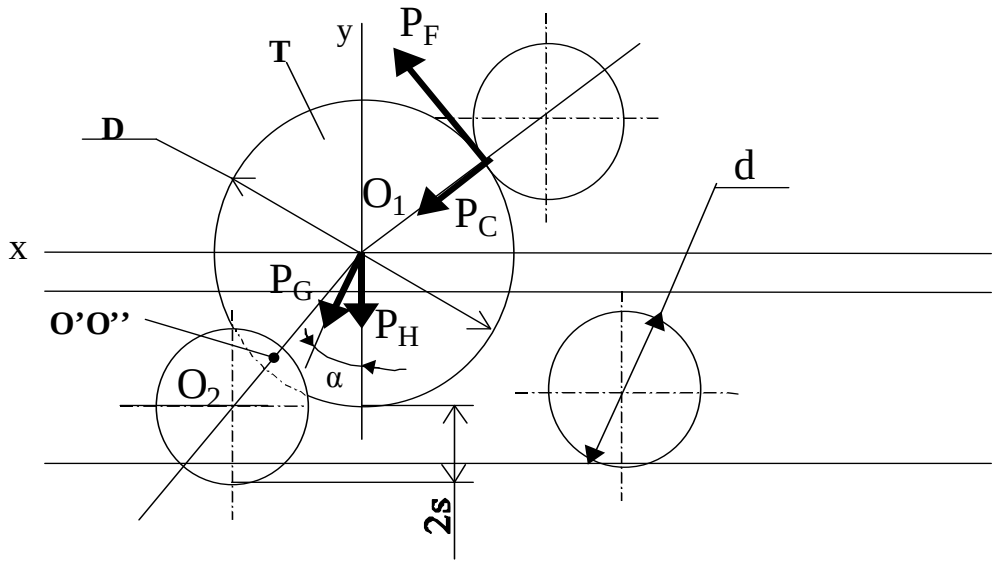

Fig.3. Schematic of particle interactions in aerated gravity flow: T, test particle; O'O'', instantaneous axis of rotation of a test particle.

The calculation scheme allows to determine the momentum of hydrodynamic pressure forces in the following way

$$M_D = \frac{d\left(p_d(y)\right)\cdot D^4}{dy}\cdot\frac{\pi\left((d+D)^2-(d+s)^2\right)^{\frac{1}{2}}}{8(d+D)}\cdot\cos\left(\arcsin\frac{D-d+4s}{\left((d+D)^2-(d+s)^2\right)^{\frac{1}{2}}}\right) \qquad (6)$$

where *pd(y)* is the hydrodynamic pressure, which equals to the second item in the right part of Eq.(2).

Then taking into consideration the additional momentum of forces (6) appearing in aerated gravity flows we can describe the segregation driving force as follows

$\Delta M = M - M_0$ (7)

where $M = M_G + M_F + M_C + M_D$ is the total momentum of gravity, friction, impact and hydrodynamic pressure forces, acting on the test particle relatively to their instantaneous axis of rotation, *M0* is the analogous momentum of forces acting on an average particle in a conventionally uniform medium at the same flow conditions [2].

Equation (5) was integrated numerically for the initial condition

$c(0,x,y) = c_0$

where c_0 is the mean concentration of test particles.

Boundary conditions were formulated in the following way

$$D_{dif}\cdot\frac{\partial c}{\partial y} = D_m\cdot c\cdot\frac{\partial \ln s}{\partial y} = K\cdot\Delta M\cdot c = 0, \qquad \text{if} \quad y = 0, h$$

$c(\tau,0,y) = c_0$

The profiles of velocity and fraction of void volume presented in the previous paper part (Fig.2) were used to obtain *u* and *s* values. The calculated results shown in Figs. 4 and 5 were obtained on the basis of the two different calculation versions. The first version takes

into account all the particle fluxes in accordance with Eq.(5) and the second one ignores the migration flux, i.e. it assumes that *Dm=0*.
It should be pointed out that the adequate modeling results in a case of non-aerated gravity flow of particles differing in size may be obtained often without taking into consideration the migration flux as it shown in Fig.4. However, analyzing the concentration profiles calculated in case of aerated flows (Figs.4,5) we observed the considerable migration effects in the vicinity of the free surface of the bed and the segregation increase in the central part of the bed. These phenomena are explained by the shear rate increase in all the bed depth and expanding the loose zone in the upper part of the bed.

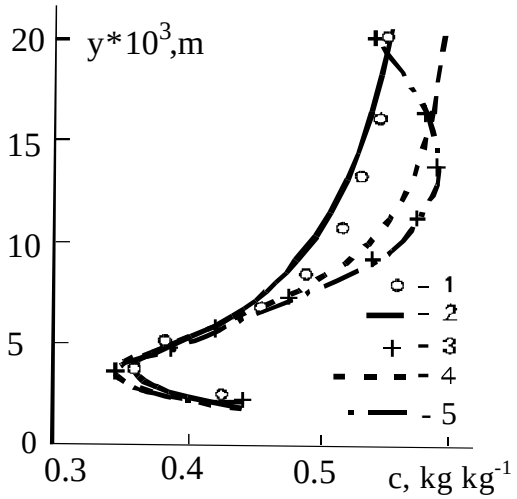

Fig.4. Concentration profiles in the gravity flow of silica gel granules (-3.75+3.5mm - 50%; -4.25+4.0mm -50%) for various aerating air velocity towards the bed bottom: 1 - w/w_m=0 (experimental [1]); 2 - w/w_m=0 calculated at $D_m=0$); 3 - w/w_m=-0.46 (experimental); 4 - w/w_m=-0.46 (calculated at $D_m=0$); 5 - w/w_m=-0.46 (calculated according to (5)).

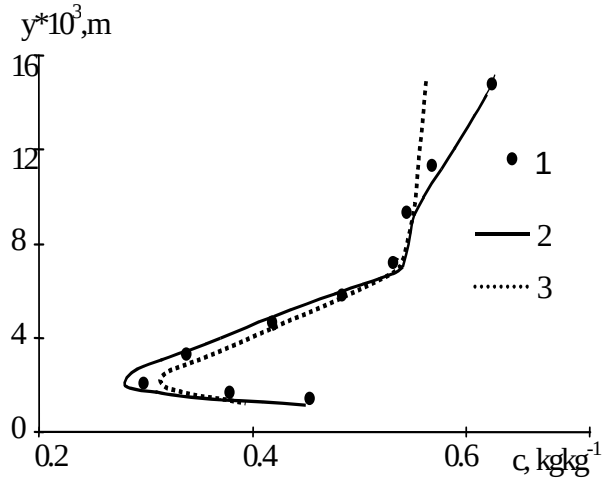

Fig. 5. Concentration profiles in the aerated gravity flow of superphosphate granules (-2.2+2.0mm -50%; -2.8+2.6mm -50%) for aerating air velocity w/w_m=0.405 towards the bed bottom: 1 – experimental [1]; 2 – calculated according to Eq.(5); 3 – calculated without migration flux $(D_m=0)$.

Thereby it is important to note that the same value of segregation coefficient *K* is used for modeling in aerated and non-aerated flows. This fact can be considered as an indirect proof of the relatively high forecasting properties of the mathematical model.
Thus the investigation results allowed us to maintain that the quasidiffusional separation (migration) is one more basic segregation mechanism in aerated gravity flows of granular materials.

Conclusions

In order to reveal more accurately physical mechanisms of aeration influence on particle segregation in gravity flows the mathematical modeling of segregation dynamics was carried out. This modeling has taken into account the fluxes of nonuniform particles in consequence of convection, quasidiffusional mixing, segregation and quasidiffusional separation (migration). The results of the mathematical modeling were comprised with experimental data. The comparison has shown that these results are quite satisfactory. It is found out that the quasidiffusional separation (migration) is one more basic segregation mechanism in aerated gravity flows of granular materials.

Biofouling Control in Cooling Water

T. Reg. Bott
Department of Chemical Engineering, University of Birmingham, Birmingham B15 2TT, U.K.

Keywords: Biofouling, Cooling Water, Chemical Control, Physical Control
Topic: Environmental Engineering and Management

Abstract

An important aspect of environmental engineering is the control of greenhouse gas emissions. Fossil fuel fired power stations for instance, represent a substantial contribution to this problem. Unless suitable steps are taken the accumulation of microbial deposits (biofouling) on the cooling water side of the steam condensers, can reduce their efficiency and in consequence, the overall efficiency of power production, with an attendent increase in fuel consumption and hence CO_2 production. Biofouling control therefore, is extremely important and can be exercised by chemical or physical techniques or a combination of the two. The paper gives some examples of the effectiveness of different approaches to biofouling control.

1 Introduction

The importance of good energy management is becoming far more demanding than in the past. The substantial increase in energy costs and the threat of climate change due to greenhouse gas emissions, makes it imperative that all steps are taken to reduce energy usage. Of particular importance is the effectiveness of cooling water, specially in the steam condensers of fossil fuel fired power stations, to maintain electrical energy output per tonne of fuel at its highest possible level.

Despite efforts to provide an effective design of heat exchanger, and careful attention to the maintenance of the design operating conditions, it is likely that fouling on the water-side of the heat exchangers will occur unless suitable precautions are taken. The common practice of taking water from natural sources such as rivers and lakes for cooling purposes, means that it will contain micro organisms, which will colonise the heat transfer surfaces, to the detriment of cooling efficiency, The problem will be aggravated by the fact that the temperature of the water-side surface in the heat exchanger, is usually close to the optimum temperature for maximum microbial growth. In addition water from natural sources will contain nutrients from the breakdown of naturally occurring organic material. Unless this bioactivity is controlled the efficiency of the heat exchanger will be seriously reduced. In fossil fuel fired power stations this will require additional fuel to be burnt to maintain the required electricity output with an attendant increase in the emission of green house gases There are basically two methods of controlling this problem, chemical and physical, that might be used separately or in some sort of combination. Three conferences held in Portugal, Melo et al (1987), Melo et al (1992) and International Water Association and Collaborators (2002) did much to stimulate interest is these techniques and their effective use. In addition conferences organised by EPI have also covered aspects of the associated technology. The most recent conference was held inTomar, Portugal in 2007, organised by Müller-Steinhagen et al (2007).

2 Chemical Control

In essence chemical control generally involves the use of biocides to kill the micro organisms in *the cooling* water, or biostats to reduce their activity. For many years the preferred biocide was chlorine because it was relatively cheap and available. However its use is becoming

severely restricted on account of its detrimental effects on the quality of the water discharged back to the natural environment from where it was abstracted and its effect on other living creatures including humans. In contact with organic material in the natural environment chlorine can form chloromethanes that are carcinogenic. An alternative to the discharge of chlorine-contaminated water is to dechlorinate before disposal. The techniques for dechlorination are likely to add considerably to the operating costs. As a result ther are efforts being made to provide alternatives and to be economical in their application. A wide range of chemicals is used as a basis for biocides. They may be classified as oxidising or non-oxidising. Oxidising agents include; chlorine and chlorine yielding chemicals, ozone and hydrogen peroxide. Amongst the non oxidising compounds are amines, heavy metal compounds, aldehydes, organo-bromine compounds and isothiazolones.

So-called “environmentally friendly” biocides are generally those that have a relatively short life after application, breaking down to innocuous products. Simple examples are ozone which reverts to oxygen on decomposition and hydrogen peroxide that breakdown to water. Alternatives to these inorganic chemicals usually involve complex organic compounds that readily break down after application. It also has to be appreciated that sometimes these breakdown products are nutrients for micro organisms!

Clearly the objective is to remove any biofilm as it forms. In order to be economical and effective the technology of dosing has to be carefully considered. The addition of chemicals to cooling water may be made in three ways;

a) Continuous. The maintenance of a fixed concentration in the circulating water. The dose depending on the concentration and species of the micro organisms present.

b) Shock. An intermittent dose of relatively high concentration, maybe only once in 24 hours.

c) Pulse. Involves dosing on a fixed schedule but more frequently than shock dosing-maybe once per hour for example.

The method of dosing will, in general, depend on the season and the quality of the water involved. Careful choice of dosing regime based on trials, preferably in a pilot plant, will help maximise control and minimise cost. It could be beneficial to employ a side-stream test section on the cooling water system, to optimise the dosing regime, and to make comparisons between alternative biocides.

Some bacteria can develop a potential tolerance to an applied biocide, particularly biocides that affect cell membranes. A change in the dosing regime or a change in the biocide, may be effective in overcoming this drawback. Biocides that actually destroy the cell structure are more likely to be the most effective.

In pilot plant studies (Grant and Bott,2005) using *Pseudomonas fluorescens* as the biofllm forming species in single tubes, bulk water flow velocities of 0.5 and 1.3 m/s and a proprietary biocide, suggested that pulse dosing, based on comprehensive preliminary testing, is likely to be the most effective regime. This observation is not surprising since pulse dosing is the closest to continuous biocide application.

An alternative to the use of environmentally friendly biocides to meet discharge regulations is to have “zero discharge” i.e. to reuse the cooling water, with only “make up” water to replace operating losses. It would allow less costly biocides to be used but such a procedure may be costly in other ways to maintain an acceptable quality of the circulating water.

3 Physical control

In theory at least, it should be possible to control biofouling by passing the water through the exchanger at high velocity to increase the removal forces acting on the biofilm. Although this may be feasible, it it is not really practical because of the high energy requirement to overcome the large pressure drop involved. There are a number of other physical techniques

that may be applied to cooling water systems to reduce the incidence of biofouling, but it has to be said that many are still in the development stage and it remains to be seen if they are practical and economically attractive.

a) Circulation of sponge rubber balls.

The use of circulating sponge rubber balls with the cooling water, through the tubes of steam condensers has been practiced with success, for many years. The balls having a diameter slightly larger than the internal diameter of the tubes, wipe away any biofilm that begins to form. Cleaning is a random process, so that the concentration of balls in the system has to be sufficiently high to ensure that every tube receives balls frequently enough to ensure effective cleaning. In addition there has to be a replacement policy since the balls loose their effectiveness after a time due to reduced diameter through wear, but this can be made automatic through suitable design.

b) The use of inserts

The inclusion of inserts in tubes, originally intended to boost heat transfer, by the destruction of the laminar sublayer on the tube surface, are also capable of reducing the incidence of biofouling at modest water velocities. Two basic types are available; (i) Static inserts such as “Hitran” wire wound inserts that break up the laminar sublayer by creating turbulence and associated removal forces at the heat transfer surface, and (ii) inserts that oscillate in response to the water flow such as “Total “ inserts, that remove the developing biofilm by abrasion.

Both types of device will increase the pressure drop and hence the operating costs, although this may be offset to some extent by suitable design. Some data (Bott, 2001) on the effect of “Hitran” inserts on the accumulation of biofilm consisting of the slime forming species *Pseudomonas Fluorescens* demonstrate that although there is some scatter in the data, it is evident that the presence of the insert reduces the accumulation of biofilm. In one test, after 700 hours operation, the reduction of biofilm accumulation compared to an equivalent test with no insert prsent, was aproximately 33% with a water flow velocity of 0.86 m/s and approximately 64% with a water velocity of 1.27 m/s.

c) The use of ultrasound

Ultrasound has the property of disturbing liquids and the structure of solids. It is employed for instance, to remove hard mineral deposits from heat exchange surfaces exposed to high temperature combustion gases in boiler installations. It has been demonstrated experimentally (Bott, 2000) that biofilm accumulation (*Pseudomonas fluorescence*) on the inside of tubes can be reduced by the modest use of ultrasound of 20 kHz. Depending on the amplitude (20 or 40%), the length (time) and frequency of groups of bursts of ultrasound, the reduction in biofilm accumulation varied between 20 and 93%. The water flow velocity was 1m/s. Some further detail is given in Table1

A major drawback in respect of the use of ultrasound for the control of biofouling is the initial cost of the equipment and its inclusion in heat exchanger design.

Table1. Control of biofilm formation with different ultrasound treatments.

Amplitude of Ultrasound %	Number of 30s bursts	Frequency of bursts each day	Reduction of biofilm growth compared with no treatment %
20	3	1	20.0
20	3	6	65.5
20	1	8	40.3

d) Circulation of polymer fibres.

Some preliminary work (Bott, 2001) on the use of Arimid fibres to control biofouling suggests that the technique could be useful. Again using *Pseudomonas fluorescens* as the biofouling bacterium, it was shown that a concentration of fibres of 100 ppm, with a water velocity of 1.6 m/s is adequate for effective control of biofilm formation. It was noteworthy that if fibre addition was stopped, a biofilm soon began to form. Considerably more work on the technology will be required however, before it could be applied effectively for industrial cooling water. A major difficulty that would have to be faced would be the recovery of the fibres prior to the final discharge of the water. Fibre removal might also be necessary before passing the water through a cooling tower in a recirculating system to avoid potential accumulation and associated blockage problems. Some preliminary work suggests that the fibres do not accelerate the wear on the associated pumps.

4. Combined chemical and physical control

It is possible that a combination of chemical and physical techniques of control could be more effective than either solely applied.

a) Ozone and ultrasound

Experimental work using a combination of ozone and ultrasound over a four week period (Bott and Liu Tianqing, 2003), again using *Pseudomonas fluorescens* as the biofilm former and a water velocity of 1m/s demonstrated that this was a more effective control than ozone alone.. During the first week of a four week period, no treatment was applied to allow a biofilm to develop. The biofilm thickness at the end of that first week ranged from 45-60μm. Table 2 presents some of the data obtained during the subsequent three weeks, demonstrating that the application of the ultrasound (20kHz at 20% amplitude) for three minutes each day made a considerable difference to the retention of biofilm. The ozone concentration in the water during these tests was very low, since water containing an ozone concentration of around 2.2 - 2.8 mg/l was pumped into the system to be mixed with the bulk water for only three hours each day. The data contained in Table indicates that the application of ultrasound made a considerable reduction in the accumulated biofilm.

Table2. Mean biofilm thickness over a period of 28 days with different treatments.

Week	Biofilm thickness for different tubes μm	
	Ozone only	Ozone + ultrasound
2	26, 18, 17, 18	9, 8
3	43, 15, 24, 20	11, 12
4	111, 49, 60, 51	7, 5

b) Propriety biocide and inserts

Limited results (Wills et al, 2002) using Hitran inserts in conjunction with a propriety biocide have demonstrated that whereas a biocide concentration of around 50 mg/l would normally be required to control biofilm formation, but in the presence of inserts the concentration required could be as low as 10 mg/l The conditions of these tests were similar to those quoted elsewhere in this paper.

5. Concluding remarks.

This brief summary of investigations into the factors that influence biofilm formation and perhaps more importantly the opportunities for control of biofilm growth, demonstrate how the application of chemical engineering and associated technologies, can help meet the challenge of climate change and the associated impact on the well-being of humanity.

Conferences such as Chempor, do much “to spread the word” about what is possible through the application of chemical engineering principles. Furthermore the “networking” that is a direct result of conference attendance is extremely valuable in that it facilitates a combined approach to meeting the challenge.

Keywords: airlift column/reactor, slug flow, gas-liquid systems

Abstract

The present work reports a series of experiments performed in an external loop airlift column (ELARL) with a 2.74 m high riser tube. This column could be operated under the same range of operating conditions used previously by Santos (2004) in an internal loop airlift column (ILARL), using a similar aqueous glycerol solution in columns with different configurations (riser tubes with 22, 32 and 52 mm internal diameter) and injecting different gas flow rates. The objective of the present study was to analyse if similar hydrodynamic parameters could be obtained as in the ILARL column spending approximately 22% of liquid volume.

Several experiments were performed and analysed for riser tubes with 22 and 32 mm internal diameters. A 78% (w/w) aqueous glycerol solution (μ = 0.05 Pa.s) was used, for different air flow rates (15×10^{-6} to 98×10^{-6} m^3/s), and a 0.94 submergence ratio was imposed. Slug flow regime was observed for these conditions.

The experimental data of gas hold-up, velocity of gas slugs (Taylor bubbles) and liquid circulation velocity were compared with the results obtained previously for the ILARL. For the conditions used during experiments performed in the ELARL the solution viscosity was 6% lower than the value measured for the solution used in the ILARL. This discrepancy was mainly due to the impossibility of working at the same temperature as in the ILARL. In general, differences inferior to 3.3% were found in the liquid circulation velocity, 8.1% in the gas hold-up and 17% in the Taylor bubbles rise velocity.

The present study ensures that the two experimental designs lead to similar hydrodynamics parameters.

1 Introduction

In many bubble columns the gas is injected at the bottom and rises through the liquid in the shape of bubbles that induce the circulation of the liquid. When the gas rises oriented by a riser tube the flow patterns become more ordered and the liquid flow rate increases. These are called airlift columns. In the internal loop airlift column, ILARL, the liquid rises along with the gas through an internal riser tube, separates total or partially at its top, and descends between the main column and the riser tube. In the external loop airlift column configuration, ELARL, the gas and liquid rise through an external tube (riser) and the liquid flows down through the main column (downcomer).

* Corresponding author. Tel + 351-22-8340500. E-mail:mte@isep.ipp.pt

Airlift columns are commonly used as gas-liquid reactors, in wastewater and sewage treatment processes, in nuclear, pharmaceutical and biochemical industries. The design of this type of columns involves the knowledge of pressure drop, gas hold-up and liquid recirculation velocity. This last parameter influences the mixture characteristics of these columns and also heat and mass transfer coefficients, when mass transfer between the two phases (gas and liquid) occurs. Each of these factors is conditioned by the physical and chemical properties of the gas and liquid, by the gas and liquid flow rates and configuration (geometry) of the bubble column.

In the literature there are few studies about ILARL and ELARL especially for slug flow regime. In this regime, long bullet-shaped bubbles, usually called Taylor bubbles, occupy most of the tube cross section. Between the gas bubble and the tube wall flows a thin film of liquid and at the bubble rear there is a separated region, the wake, characterized by strong mixing. It is known that the flow pattern in the wake, in the liquid around the bubble and between gas slugs determine the mixing level in gas-liquid slugging columns. In the literature there is also a lack of information for laminar flow in the liquid, obtained when liquids of high viscosities are used

To enlarge the knowledge about the performance of airlift columns/reactors, in the slug flow regime, an ILARL column was designed by Santos (2004) (see also Santos et al., 2005) to ensure high precision and quality of the experimental results, with very simple experiments. This ILARL column can be operated with different submergence ratios of the riser tube and a wide range of operating conditions. In that study several hydrodynamic parameters were studied, namely: gas hold-up and liquid superficial velocity in the internal riser tube, bubbles rise velocity, bubble length and average number of gas slugs in the internal tube.

The disadvantage of this ILARL column was the volume of liquid required to perform the experiments. When the design of an ELARL column was considered the advantage was that the volume of liquid used could be considerably reduced when compared to the ILARL column. The ELARL built, with a 2.74 m high riser tube, could be operated under the same range of operating conditions used previously in the ILARL column, i.e., different viscosities of the liquid solutions in columns with different configurations (riser tube with 22, 32 and 52 mm internal diameter), injection of different gas flow rates and variable submergence ratios. The objective of the present study was to analyse if similar results for the gas hold-up, liquid superficial velocity and bubbles rise velocity in the riser tube could be obtained as in the ILARL column but spending approximately 22% of liquid volume.

2 Experimental set-up and measurements

The experimental set-up built for the hydrodynamic study of an ELARL column is sketched in Fig. 1. This set-up, which has a main column (downcomer) in flexible and transparent PVC, of 50 mm of internal diameter and 2.75 m of height, can be operated for different submergence ratios and a wide range of operating conditions. These conditions correspond to different types of flow regimes in the main liquid between bubbles and in the wake of gas slugs. These regimes can be obtained using different liquid viscosities, in external riser tubes with different internal diameters and injecting different gas flow rates. In the experiments performed transparent acrylic riser tubes with 22 and 32 mm I.D. were used. The riser tubes were 2.74 m high and the liquid free surface in the downcomer was 0.17 m below the top of the risers, which set a submergence ratio of 0.94. The liquid used was a 78% (w/w) aqueous solution of glycerol with ρ = 1203 kg/m^3 and μ = 0.05 Pa.s, for a temperature of 21ºC. The air injected at the bottom of the riser tube, with flow rates ranging from 15×10^{-6} to 98×10^{-6} m^3/s, was provided from a compressed-air line. The experimental values of gas hold-up, ε, rise velocity of the gas slugs, v_s, and liquid circulation velocity in the riser tube, v_L, were determined.

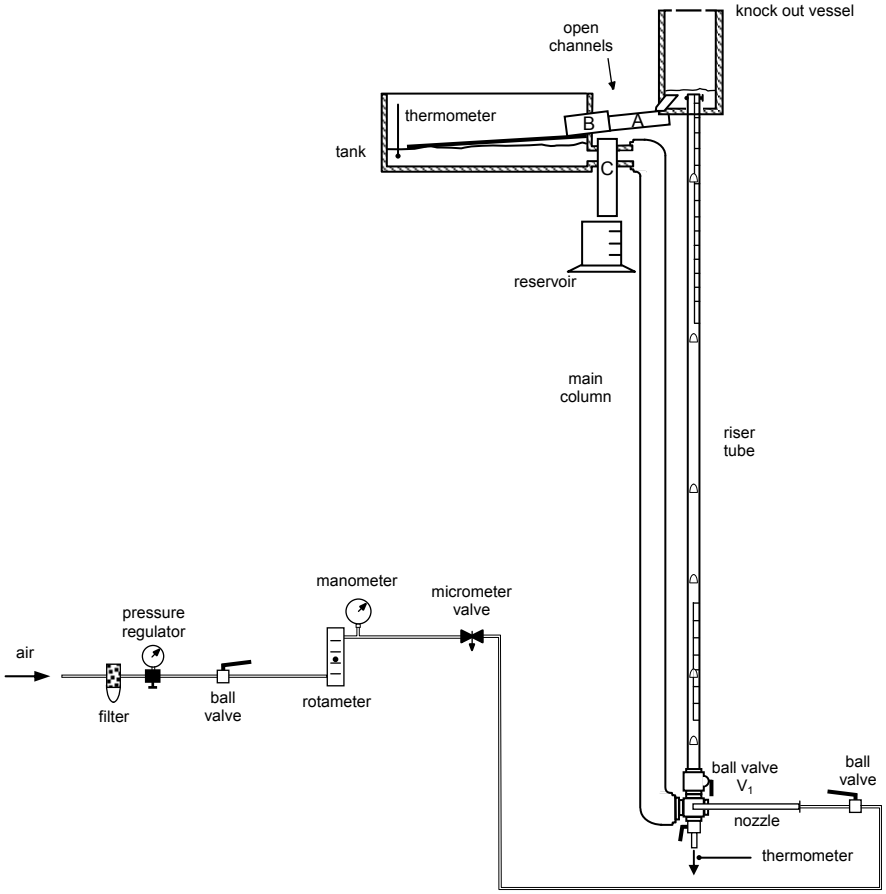

Figure 1 - Sketch of the experimental set-up

The air was continuously injected through a nozzle at the bottom of the riser tube generating the circulation of liquid, upwards in the riser tube and downwards in the main column (downcomer). At the top of the riser, the gas was separated from the liquid in a knock out vessel and the liquid was directed to a tank through a system of two small open channels. In the tank, the liquid was discharged on a wide ramp, with a small inclination, where the velocity of the liquid was greatly reduced in order to obtain the liquid free of small bubbles dispersed. The tank was connected to the main column allowing the liquid to flow downwards along the downcomer. The temperature of the liquid was measured regularly to verify if any change in the viscosity had occurred. The viscosity of the liquid was measured with a rotating Brookfield viscometer.

To measure the gas hold-up, valve V_1 at the bottom of the riser tube was closed. Sometime after the closure of the tube, the level of liquid was measured with a tape measure fixed at the top of the riser. This determination was repeated ten times for each gas flow rate.

The system of two small open channels that connected the knock out vessel to the tank was used to measure the volumetric flow rate of liquid circulating in the airlift. When the flow was steady and the measurement was to be made, the position of channel B (channel closer to the tank) was changed so the flow of liquid was directed to channel C that discharged the liquid into a reservoir. The volume of liquid collected (approximately 10^{-3} m^3), for an interval of time registered with a chronometer, was then weighted on an analytical balance and the mass flow rate was calculated. It was then converted to volumetric flow rate with the density experimentally determined at the temperature of the experiment. Because the tank was designed with large dimensions (0.50 m length and 0.20 m width), the liquid level (and the submergence ratio imposed) maintains essentially constant when the volume of liquid was

removed during flow rate measurements; the liquid level in the tank lowered approximately 8 mm, which is responsible for a decrease of only 3.5% in the volumetric flow rates. The procedure described for the determination of the mass flow rate was repeated six times and until, at least, three values of flow rate with deviations inferior to 5% were obtained.
The rise velocity of the gas slugs in the riser tube was determined by filming a section of the tube with a video camera that recorded 25 frames per second, and was placed 1 m away. The section with 0.25 m of length was marked with two white stripes, 2 m above the injection of gas. The videos were transferred to a computer using a *Pinnacle* video board and its software, and the frames were analysed with the software *Adobe Premiere 6*. The time of rise of a gas slug between the first mark and the second mark was given by the number of frames visualised between the reference positions, which correspond to the nose coincident with each mark. The rise of 8 to 12 consecutive gas slugs was analysed and an average value of the rise velocity was determined. Whenever a gas slug coalesced with the one above it, in the frames in analysis, its rise velocity was not calculated.

3 Results and discussion

The results obtained in the ELARL column are compared with the results presented by Santos et al. (2005) and Santos (2004) for an ILARL column operating with a similar aqueous glycerol solution. The liquid flow regime in the experiments was laminar in the main liquid between Taylor bubbles ($53 < Re_{v_L} < 378$, where Re_{v_L} is the Reynolds number of the flowing liquid) and transitional in their wake ($156 < Re_V < 532$, where Re_V is the Reynolds number of the flowing liquid based on the liquid velocity relative to the bubble) according to Pinto *et al.* (1998).

In Figures 2 and 3 the experimental values of the gas hold-up, ε, obtained in the ILARL and ELARL columns are plotted against the superficial liquid velocity in the riser tube, v_L, for the 22 and 32 mm I.D. riser tubes, respectively. The error bars were also drawn in these figures representing the total uncertainties associated with the average experimental values of gas hold-up. The experimental results obtained in the ELARL with the 22 mm I.D. riser tube are in accordance with the ILARL, with deviations less than 7.2%, as depicted in Figure 2. Exception must be made for the lowest velocity where the difference is 17.8%. For the results of the 32 mm I.D. riser tube, shown in Figure 3, differences are lower than 8.1%. The lower values obtained in the ELARL may be due to the lower viscosity of the liquid used in the present work; the impossibility to control the temperature did not allow the same liquid viscosity as in the ILARL, although a similar aqueous glycerol solution was used in both situations.

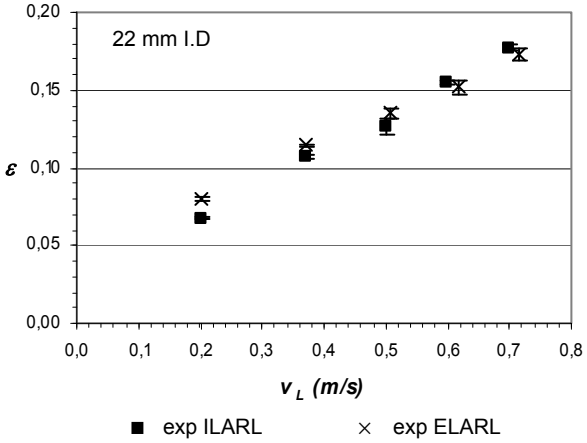

Figure 2 - Experimental values of ε for an ILARL and ELARL column with a riser tube of 22 mm I.D. and laminar regime in the liquid.

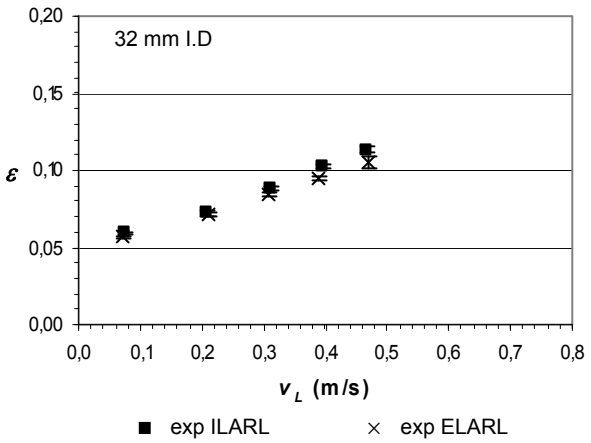

Figure 3 - Experimental values of ε for an ILARL and ELARL column with a riser tube of 32 mm I.D. and laminar regime in the liquid.

As reported by Santos *et al*. (2005) and Santos (2004) for the ILARL column, the results in both riser tubes diameters are well predicted by theory for laminar flow regime in the liquid.

The experimental values of Taylor bubbles rise velocity, v_s, for the ILARL and the ELARL columns are represented in Figures 4 and 5 against v_L, for the 22 and 32 mm I.D. riser tubes, respectively. The error bars associated with the data are also drawn. The experimental results for the 22 mm I.D. riser (Fig. 4) show differences lower than 17% between the ELARL and the ILARL. Again for the lowest liquid velocity the deviation is higher with a value of 23%. It should be emphasized that the differences observed for v_L > 0.3 m/s are within the uncertainties associated with the experimental determinations. Better results can be observed in the 32 mm I.D. riser tube (Fig. 5) where the differences are lower than 10.2%.

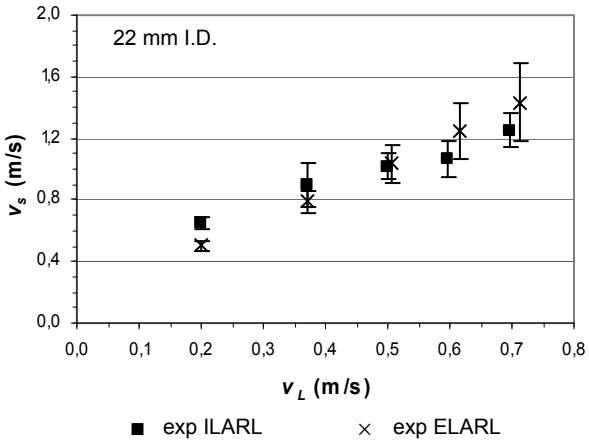

Figure 4 - Experimental values of v_S for an ILARL and ELARL column with a riser tube of 22 mm I.D. and laminar regime in the liquid.

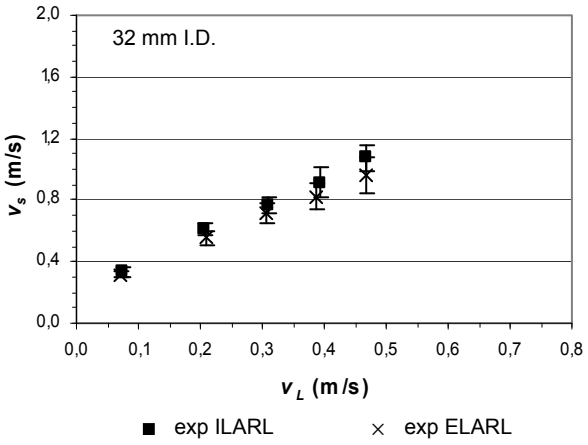

Figure 5 - Experimental values of v_S for an ILARL and ELARL column with a riser tube of 32 mm I.D. and laminar regime in the liquid.

In previous studies Santos *et al*. (2005) and Santos (2004) compared the experimental Taylor bubble velocities obtained in the ILARL with the predictions made by Nicklin *et al.* (1962) for laminar flow regime in the liquid and concluded that they are in reasonable good agreement. They obtained deviations less than 5% for the 32 mm I.D. riser tube and less than 27% for the 22 mm I.D. riser tube.

In Figures 6 and 7 the experimental values (and respective error bars) of v_L are represented against the gas flow rate, Q_G, for the 22 and 32 mm I.D. riser tube, respectively.

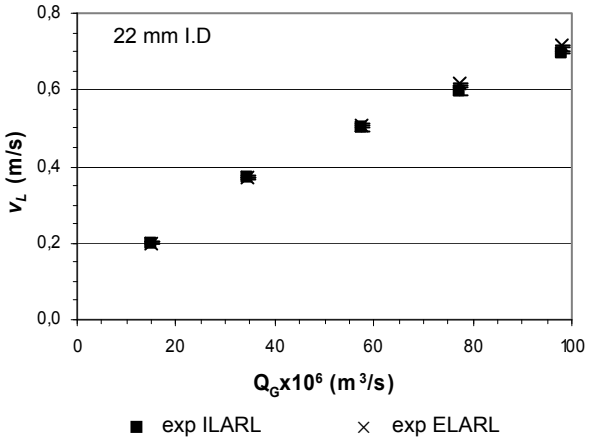

Figure 6 - Experimental values of v_L for an ILARL and ELARL column with a riser tube of 22 mm I.D. and laminar regime in the liquid.

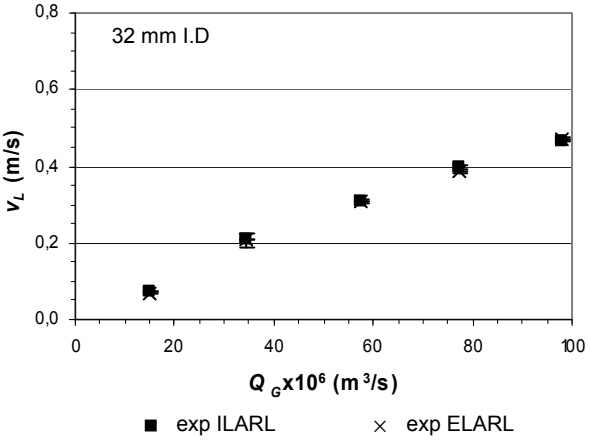

Figure 7 - Experimental values of v_L for an ILARL and ELARL column with a riser tube of 32 mm I.D. and laminar regime in the liquid.

As depicted in these figures good agreement is observed between the results of the ELARL and ILARL columns. In Figure 6 (22 mm I.D riser tube) the deviations are lower than 3.3% and in Figure 7 (32 mm I.D. riser tube) the differences do not exceed 1.8% (except for the lowest air flow rate for which the deviation is 5.1%).

The previous experimental values for v_L in the ILARL were compared by Santos *et al*. (2005) and Santos (2004) with the predictions of a hydrodynamic model (based in mechanical energy balances along the circulation path) developed by Sena Esteves (1998), valid for laminar regime in the main liquid. The model underpredicted the experimental results with deviations lower than 33% in the 22 mm I.D. riser and 17% in the 32 mm I.D. riser.

4 Conclusions

Hydrodynamic parameters, namely gas hold-up, Taylor bubble rise velocity and superficial liquid velocity in the riser tube, obtained in an ELARL column were compared with the results of an ILARL column. In both airlifts aqueous glycerol solutions with similar viscosities (0.05 Pa.s) were used with riser tubes of 22 and 32 mm I.D. The operating conditions selected guaranteed laminar flow regime in the liquid between bubbles and transitional flow regime in the bubble wake.

The experimental values of gas hold-up in the ELARL do not differ more than 8.1% from the ILARL results. The experimental values of Taylor bubble rise velocity show reasonable agreement with the results obtained in the ILARL, with differences lower than 17%. The experimental results of superficial liquid velocity in the riser tube obtained in the ELARL are in accordance (deviations less than 3.3%) with the results obtained in the ILARL.

The present study ensures that the two experimental designs lead to similar hydrodynamic parameters. With the ELARL configuration it is possible to spend approximately 22% of the liquid volume used in the ILARL configuration.

New Journals IMPACTING Science

Recent Patents on Electrical Engineering

publishes review articles by experts on recent patents in electrical engineering. A selection of important and recent patents on electrical engineering is also included in the journal. The journal is essential reading for all researchers involved in electrical engineering science.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Recent Patents on Biomedical Engineering

publishes review articles on recent patents in the field of biomedical engineering e.g. new medical devices and biomaterials. A selection of important and recent patents on biomedical engineering is also included in the journal. The journal is essential reading for all researchers involved in biomedical engineering.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Current Molecular Pharmacology

publishes the latest developments in cellular and molecular pharmacology. Each issue contains in-depth reviews written by leaders in the field.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 140.00

Recent Patents on Chemical Engineering

publishes review articles by experts on recent patents in chemical engineering. A selection of important and recent patents on chemical engineering is also included in the journal. The journal is essential reading for all researchers involved in chemical engineering science.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Recent Patents on Materials Science

publishes review articles by experts on recent patents in all fields of materials science. A selection of important and recent patents on materials is also included in the journal. The journal is essential reading for all researchers involved in materials sciences.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Recent Patents on Mechanical Engineering

publishes review articles by experts on recent patents in mechanical engineering. A selection of important and recent patents on mechanical engineering is also included in the journal. The journal is essential reading for all researchers involved in mechanical engineering science.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Current Radiopharmaceuticals

publishes original research articles on all aspects on radiolabelled compound preparations, including radio imaging techniques, therapies, preparation and application of radionuclide compounds.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 140.00

Recent Patents on Computer Science

publishes review articles by experts on recent patents in all areas of computer science. A selection of important and recent patents on computer science is also included in the journal. The journal is essential reading for all researchers involved in computer science.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 340.00

Current Drug Abuse Reviews

publishes reviews and meta-analyses on all the latest advances on alcohol and drug abuse and addiction.

Volume 1, 3 Issues, 2008
Personal Subscription: $ 140.00

Current Aging Science

publishes frontier review and experimental articles in all areas of aging and age-related research that may influence longevity. The journal is essential reading for gerontologists, neuroscientists, clinicians, health science planners, granting agencies and pharmaceutical scientists.
